The gilding of buttons is done in the following way: When the buttons, which are of copper, are made, they are dipped into dilute nitric acid to clean them, and then burnished with a hard black stone. They are then put into a nitric solution of mercury, and stirred about with a brush till they are quite white. An amalgam of gold and mercury is then put into an earthen vessel with a small quantity of dilute nitric acid, and in this mixture the buttons are stirred, till the gold attaches to their surface. They are then heated over the fire, till the mercury begins to run, when they are thrown into a large cap made of coarse wool and goats' hair, and in this they are stirred about with a brush. The mercury is then volatilized by heating over the fire in a pan, to the loss of the article, and injury of the workmen's health; though the greater part might be recovered, with less injury to the operators.

Painting with gold upon porcelain or glass is done with the powder of gold, which remains behind after distilling the aqua regia from a solution of that metal. It is laid on with borax and gum water, burned in, and polished. The gilding of glass is commonly effected by covering the part with a solution of borax, and applying gold leaf upon it, which is afterwards fixed by burning.

Gilding in oil is performed by means of a paint sold under the name of gold size. It consists of drying oil, (that is to say, linseed oil boiled upon litharge,) and mixed with yellow ochre. It is said to improve in its quality by keeping. This is laid upon the work; and when it has become so dry as to adhere to the fingers without soiling them, the gold leaf is laid on, and pressed down with cotton. This method of gilding is proper for work intended to be exposed to the weather.

The method of gilding in burnished gold consists in covering the work with parchment size and whiting, thinly laid on at five or six different times. This is covered with a yellow size made of Armenian bole, a little wax, and some parchment size; but in this, as in most other compositions used in the arts, there are variations which depend on the skill or the caprice of the artists. When the size is dry, the gold is applied upon the surface previously wetted with clear water. A certain number of hours after this application, but previous to perfect hardening of the composition, the gold may be very highly burnished with a tool of agate made for this purpose. This gilding is fit only for work within doors; for it readily comes off upon being wetted.

The edges of the leaves of books are gilded by applying a composition of one part Armenian bole, and one quarter of a part of sugar-candy, ground together with white of eggs. This is burnished while the book remains in the press, and the gold is laid on by means of a little water.

Leather is gilded either with leaf brass or silver, but most commonly by the latter, in which case a gold-coloured varnish is laid over the metal. Tin-foil may be used instead of silver-leaf for this less perfect gilding, upon such works as do not possess flexibility.

GIMBALS, in sea affairs, the brass rings by which a sea compass is suspended in its box, so as to counteract the effect of the ship's motion, and keep the card horizontal.

GIMBLETING, a term applied to the anchor to denote the action of turning it round by the stock, so that the motion of the stock appears similar to that of the handle of a gimblet when it is employed.

GIN. See GENEVA.

GIN, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved, that goes over the wheel at the top.

GINANNIA, a genus of the class and order enneandria monogynia. The calyx is double, both one-leaved, petals three-fringed and spreading; germ pedicelled, with a membranaceous wing at top. Legume. There is one species, a shrub of Guiana.

GINKGO, or maiden hair-tree, of the dioecia class (order and character unknown,) a large tree of Japan, with leaves resembling the adiantum, whence its popular name.

GINORA, a genus of the dodecandria monogynia class and order. The calyx is six-cletted; petals six; capsules one-seeded, four-celled, four-valved, coloured, many seeds. There is one species, an elegant shrub of Cuba, bearing handsome large red flowers.

GINGER. See AMOMUM.

GINSENG. See PANAX.

GIRDERS, in architecture, some of the largest pieces of timber in a floor. By the building act, no girder is to lie less than 10 inches into the wall, and the ends to be laid in loam.

GIRT, in the measuring of timber, is the circumference of a tree, though some use this word for the fourth part of the circumference only, on account of the use made of it. The square of the fourth part is considered as equal to the area of the section of the tree, which square therefore multiplied by the length of the tree is accounted the solid content.

GLACIERS is a name given to those extensive fields of ice and hardened snow, which occur in elevated mountainous districts, but especially in the Alps of Switzerland and Savoy.

The most remarkable phenomenon attending the glaciers is their near approach to the usual vegetation of summer, being separated only by the intervention of a few feet from the chilling influence of an endless bed of ice, which seems impenetrable to the rays of the sun. The depth of these astonishing accumulations of frozen fluid varies from 80 to 600 feet.

GLACIS, in fortification, that mass of earth which serves as a parapet to the covered way, sloping easily towards the champaign, or field. The glacis, otherwise called esplanade, is about six feet high, and loses itself by an insensible diminution in the space of ten fathoms.

GLADIATORS, in antiquity, persons who fought generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity, though sometimes freemen made profession of it, like our prize-fighters for a livelihood. The Romans borrowed this cruel diversion from the Asiatics. They were all first sworn that they would fight till death; and if they failed they were put to death either by fire, swords, clubs, whips, &c. It was usual with the people or emperor to grant them life when they shewed no signs of fear. Augustus decreed that it should always be granted them. Constantine the Great had the humanity and courage to abolish the custom, after it had prevailed near six hundred years; but it revived under Constantius Theodosius and Valentinian, and was finally suppressed by the Emperor Honorius.

GLAREOLA, the *pratincole*, in natural history, a genus of birds of the order Grallæ. Generic character: bill strong, strait, short, hooked at the end; nostrils at the base, linear and oblique; feet four-toed; toes long, slender, connected at the base by a membrane; tail forked, consisting of twelve feathers. There are three species, of which the principal is P. austriaca; this is about as large as a blackbird, lives on water insects and on worms; is found in great numbers on the banks of the Rhine.

GLASS is an artificial substance, formed by the fusion of siliceous earth with various salts and metallic oxides, and possessing a high degree of transparency. It is one of the most useful and ornamental substances which the arts have yet produced. Various speculations have been offered to the world on the origin of this substance, which seem totally unworthy of notice: the most probable fact connected with the subject is that recorded by Pliny, which is as follows:

Some merchants with soda as part of their freight, had cast anchor at the mouth of the river Belus, in Phœnicia, and were dressing their dinner on the sand, making use of large lumps of the soda as supports for their kettles. The heat of the fire melted the soda, and the siliceous earth together; the result was glass. The hint was not lost, and a manufacture in that trading country was instantly established, and to this place it was for a long time confined. Glass was undoubtedly made in great perfection among the ancients. In their accounts we read of drinking glasses, glass prisms, and coloured glasses of various kinds. Glass was first used for windows in the third century of the Christian æra, but it did not come into common use till very long after this. There are five distinct kinds of glass at present manufactured:—

1. Flint glass, or glass of lead.
2. Plate glass, or glass of pure soda.
3. Crown glass, the best window-glass.
4. Broad glass, a coarse window glass.
5. Bottle, or coarse green glass.

1. *Flint glass*, so named because the siliceous ingredient was originally employed in the form of ground flints. It is now made of the following composition:—

Purified Lynn sand.	100 parts
Litharge or red lead,	60
Purified pearl ash,	30

To correct the green colour derived from combustible matter, or oxide of iron, a little black oxide of manganese is added, and sometimes nitre and arsenic. The fusion is accomplished usually in about thirty hours.

2. *Plate Glass.* Good carbonate of soda, procured by decomposing common salt with pearl ash, is employed as the flux. The proportion of the materials is,

Pure sand,	43.0
Dry subcarbonate of soda,	26.5
Pure quicklime,	4.
Nitre,	1.5
Broken plate glass,	25.0
	100.0

About seventy parts of good plate glass may be run off from these materials.

3. *Crown or fine window-glass.* This is made of sand vitrified by the impure barilla, manufactured by incineration of sea weed, on the Scotch and Irish shores. The most approved composition is,

	By measure.	By weight.
Fine sand purified,	5	— 200
Best kelp ground,	11	— 330

These ingredients are mixed, and then thrown into the fritting arch, where the sulphur of the kelp is dissipated, and the matters are thoroughly incorporated, forming, when withdrawn at the end of four hours, a greyish-white tough mass, which is cut into brick-shaped pieces, and after concretion and cooling, piled up for use. By long keeping, a soda efflorescence forms on their surface. They are then supposed to have become more valuable. These bricks are put into the melting pots, and sometimes a proportion of common salt is thrown in towards the end of the operation, if the vitrification has been imperfect. Gehlen, some time before his death, was occupied with experiments on the preparation of glass, by means of sulphate of soda. Prof. Schweigger has lately published the result of his trials. He found that the following proportions were the best:—

Sand; - - -	100
Dry sulphate of soda, -	50
Dry quicklime in powder, -	17 to 20
Charcoal, - - -	4

This mixture always gives a very good glass without any addition whatever. During the fusion, the sulphuric acid is decomposed and drawn off, and the soda unites with the silica. The sulphate of soda vitrifies very imperfectly, when mixed alone with the silica. The vitrification succeeds better when quicklime is added; and it succeeds completely, when the proportion of charcoal in the formula is added; because the sulphuric acid is thereby decomposed and dissipated. This decomposition may be either effected during the making of the glass, or before, at the pleasure of the workmen.

4. *Broad Glass.* This is made of a mixture of soap-boilers' waste, kelp, and sand. The first ingredient consists of lime used for rendering the alkali of the soap-boiler caustic, the insoluble matter of the kelp or barilla, and a quantity of salt and water, all in a pasty state. The proportions necessarily vary; 2 of the waste, 1 of kelp, and 1 of sand, form a pretty good broad glass. They are mixed together, dried, and fritted.

5. *Bottle Glass* is the coarsest kind. It is made of soaper's waste and river sand, in proportions which practice must determine according to the quantity of the waste; some soap-boilers extracting more saline matter, and others less from their kelps. Common sand and lime, with a little common clay and sea salt, form a cheap mixture for bottle glass.

As far as observation has hitherto directed us, it appears to be a general rule, that the hardness, brittleness, elasticity, and other mechanical properties of congealed bodies, are greatly affected by the degree of rapidity with which they assume the solid state.. This, which no doubt is referrible to the property of crystallization, and its various modes, is remarkably seen in steel and other metals, and seems to obtain in glass. When a drop of glass is suffered to fall into water, it is found to possess the remarkable property of flying into minute pieces, the instant a small part of the tail is broken off. This, which is commonly distinguished by the name of Prince Rupert's drop, is similar to the philosophical phial, which is a small vessel of thick glass suddenly cooled by exposure to the air. Such a vessel possesses the property of flying in pieces, when the smallest piece of flint or angular pebble is let fall into it, though a leaden bullet may be dropped into it from some height without injury. Many explanations have been offered, to account for these and other similar appearances, by referring to a supposed mechanism or arrangement of the particles, or sudden confinement of the matter of heat. The immediate cause, however, appears to be derived from the fact, that the dimensions of bodies suddenly cooled remain larger than if the refrigeration had been more gradual. Thus the specific gravity of steel hardened by sudden cooling in water is less, and its dimensions consequently greater than that of the same steel gradually cooled. It is more than probable, that an effect of the same nature obtains in glass; so that the dimensions of the external and suddenly cooled surface remain longer than are suited to the accurate envelopement of the interior part, which is less slowly cooled. In most of the metals, the degree of flexibility they possess, must be sufficient to remedy this inaccuracy as it takes place, but in glass, which, though very elastic and flexible, is likewise excessively brittle, the adaptation of the parts, urged different ways by their disposition to retain their respective dimensions, and likewise to remain in contact by virtue of the cohesive attraction, can be maintained only by an elastic yielding of the whole, as far as may be, which will therefore remain in a state of tension. It is not therefore to be wondered at, that a solution of continuity of any part of the surface should destroy this equilibrium of elasticity; and that the sudden action of all the parts at once, of so brittle a material, should destroy the continuity of the whole, instead of producing an equilibrium of any other kind.

Though the facts relating to this disposition of glass too suddenly cooled, are numerous and interesting to the philosopher, yet they constitute a serious evil with respect to the uses of this excellent material. The remedy of the glass-maker consists in annealing the several articles, which is done by placing them in a furnace near the furnace of fusion. The glasses are first put into the hottest part of this furnace, and gradually removed to the cooler parts at regular intervals of time. By this means the glass cools very slowly throughout, and is in a great measure free from the defects of glass which has been too hastily cooled.

The different coloured glasses owe their tints to the different metallic oxides, mixed with the glass, or materials, while in a state of fusion. *Blue* glass is formed by the oxide of cobalt; *green* by the oxide of iron or copper *violet* by the oxide of manganese; *red* by mixture of the oxides of copper and iron *purple* by the oxide of gold; *white* by the oxid of arsenic and zinc; *yellow* by the oxide of silver and by combustible bodies, and *black* from a mixture of oxide of manganese, cobalt, and iron. In this manner are made those

elegant pastes, which so faithfully imitate, and not unfrequently excel, in brilliance, their originals, the gems of antiquity. The *glass*, however, for this purpose, is prepared in a peculiar manner, and requires great nicety. It combines purity and durability. *Opaque* glass is made by the addition of the oxide of tin, and produces that beautiful imitation of *enamel* which is so much admired. Dials for watches and clocks are made in this manner.

The following is a brief account of the common process of glass blowing, and of the principal instruments used by the workmen.—The workman has a tube of iron, the end of which he dips into a pot of melted glass, and thus gathers a small quantity of glass on the end of it, he then applies the other end of the tube to his mouth and blows air through it, this enters into the body of the fluid glass, and expands it out, into a hollow globe, similar to the soap bladders blown from a tobacco-pipe. Various methods are used to bring these hollow globes into forms of the different utensils in common domestic use, and several tools.

The furnace consists of two large domes one over the other, the lower one stands over a long grating, (on a level with the ground,) on which the fuel is placed; beneath the grate is the ash pit, and a large arch leading to it, conveys air to the furnace. In the sides of the lower dome, as many holes or mouths are made as there are workmen to make use of the furnace, and before each mouth a pot of melted glass is placed; the pots are very large like crucibles, and will hold from three to four hundred weight of liquid glass, they are supported upon three small piers of brickwork, resting on the floor of the furnace. The form reverberates the flame from the roof down upon the pots, and they are placed at some distance within the furnace, that the flame may get between the wall and the pots. The upper dome is built upon the other, and its floor made flat by filling up round the roof of the lower dome with brickwork, there is a small chimney opens from the top of the lower dome into the middle of the floor of the upper one, which conveys the smoke away from it, and a flue from the upper dome leads it completely from the furnace. The upper dome is used for annealing the glass, and is exactly similar to a large oven, it has three mouths, and in different parts a small flight of steps leads up to each.

The principal implements used by the glass-blower are, a blowing-pipe, which is an iron pipe about two feet long, with rope-yarn wrapped round where the workman takes hold of it; two or three iron rods of the same length; a pair of blunt shears, and several different sized ladles, shovels, pokers, &c. and two stools.

For explaining the operation, we shall describe the method of making a goblet. The workman dips the end of his blowing-pipe, which is hot, through the hole into the melting pot, and by turning it about, a small quantity of the glass, which is called metal, sticks to the iron: this he repeats three or four times (between each dip rolling it on an iron plate, fixed on a stool, till he has got metal enough:) he then blows through the pipe, which expands the metal into a hollow globular form; and then by swinging it round his head, it lengthens out in the shape of a bladder The workman then sits down on a stool, between the two bars, across which he lays the blowing-iron, and rolls it along under his left hand, following it at the same time with the shears, in his right hand, the blades of which embrace it, and by gently putting them in the proper place, he brings the glass into the required form; meanwhile, the boy who attends him brings a lump of metal from the furnace on the end of one of the iron rods which he sticks on the bottom, and by twisting the rod round, he separates the metal from the rod, and leaves it on the glass vessel; the workman then rolls the rod and vessel as before, and with his shears brings the lump of glass into the form of a stem and foot. The boy then holds the tool against the bottom of the foot, while it is turning to flatten it; the boy next takes another iron rod, and gets a very small piece of metal on its end, this he applies to the centre of the bottom of the foot; so as to connect it to the rod; when the workman, by touching it at the neck with a wet iron, cracks the glass, so that a slight blow upon the rod with the hand will separate it from the blowing-pipe. The glass has by this time become too cold to work without heating again, which is done before the fire; the workman then returns to the stool, and again rolls the rod round with his left hand as before, and with the point of one of the blades of the shears opens the end of the glass; after which he inserts both points, and finally works it into the form of a goblet. It is now separated from the rod, and is carried on a shovel like a baker's peel by the boy to the annealing furnace, or oven, in the upper part of the furnace, where it remains in a low red heat for many hours, by which its former extreme brittleness is removed.

Window-glass is made in a similar manner, except that the liquid mass at the end of the tube is formed into a cylindrical shape, which being cut longitudinally by scissars or shears, is gradually bent back until it becomes a flat plate.

GLAUBER'S-*salt*, a cathartic or purging salt. See SODA, *sulphat of*.

GLAUCOPIS, in ornithology, a genus of birds of the order picæ. Bill incurvate, arched, the lower mandible shorter, and carunculate beneath at the base; nostrils depressed, half-covered with a membrane; tongue slit, and fringed at the tip; feet walkers. It inhabits New Zealand.

GLAZING, the crusting over earthen ware by a vitreous substance, the base of which is commonly lead. See POTTERY.

GLEANING, in law. It has been said, that by the common law and custom of England, the poor are allowed to enter and glean upon another's ground, after the harvest, without being guilty of trespass; and that this humane provision seems borrowed from the Mosaical law; but it is now positively settled, by a solemn judgment of the court of Common Pleas, that a right to glean in the harvest field cannot be claimed as a general right by every person at common law; nor as a custom by the poor of a parish, legally settled.

GLEBE, or *Glebe-land*, is a portion of land, meadow or pasture, belonging to, or parcel of the parsonage or vicarage, over and above the tithes.

GLEE, in music, a vocal composition in three or more parts, generally consisting of

more than one movement, the subject of which may be either gay, tender, or grave; bachanalian, amatory, or pathetic.

GLIRES, the name given by Linnæus to the fourth order of the mammalia; the character of which is, fore-teeth cutting, two in each jaw; no tusks; feet with claws formed for running and bounding; food, bark, roots, vegetables, &c. which they gnaw. The order includes ten genera, viz. the hystrix, cavia, castor, mus, arctomys, sciurus, myoxus, dipus, lepus, and hyrax.

GLOBE, in geometry signifies a round or spherical body, more commonly called a sphere. See SPHERE.

GLOBE, is more particularly used for an artificial sphere, on the surface of which is drawn a map or representation of the earth or of the heavens, with the several imaginary circles.

The globes commonly used are composed of plaster and paper in the following manner: A wooden axis is provided, somewhat less than the intended diameter of the globe, and into the extremes two iron wires are driven for poles: this axis is to be the beam or basis of the whole structure. On the axis are applied two spherical or rather hemispherical caps, formed on a kind of wooden mould or block. These caps consist of pasteboard or paper, laid one lay after another on the mould, to the thickness of a crown-piece; after which, having stood to dry and embody, making an incision along the middle, the two caps thus parted are slipped off the mould. They remain now to be applied on the poles of the axis, as before they were on those of the mould; and to fix them in their new place, the two edges are sewed together with packthread, &c. The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are hasped in a metalline semicircle of the size intended; and a kind of plaster made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper surface. In proportion as the plaster is applied, the ball is turned round in the semicircle, the edge of which pares off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are short of it. After such application of plaster, the ball stands to dry; when dry it is put again in the semicircle, and fresh matter applied: thus they continue alternately to apply the composition, and dry it, till the ball every where accurately touches the semicircle; in which state it is perfectly smooth, regular, and complete. The ball thus finished, it remains to paste the map on it. In order to this, the map is projected in several gores, all which join accurately on the spherical surface, and cover the whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the better to resist dust, moisture, &c. The globe itself thus finished, they hang it in a brass meridian, with an hour-circle and a quadrant of altitude, and thus fit it into a wooden horizon.

There are ten principal circles represented upon globes, viz. six greater and four lesser ones. The greater circles are the horizon, meridian, and equinoctial, as it is called on the celestial, and equator on the terrestrial globe, the ecliptic drawn along the middle of the zodiac, and the two colures. The lesser circles, of principal use, are the two tropics and two polar circles. Of these circles some are fixed, and always obtain the same position; others moveable, according to the position of the observer. The fixed circles are the equator and ecliptic, with their parallels and secondaries; which are usually delineated upon the surface of the globes. The moveable circles are the horizon, with its parallels and secondaries.

The horizon is a broad wooden circle surrounding the globe, and dividing it into two equal parts, called the upper and lower hemispheres. It has two notches, to let the brazen meridian slip up and down, according to the different heights of the pole. On the flat side of this circle are described the twelve signs, the months of the year, the points of the compass, &c. The brazen meridian is a ring of brass, divided into degrees. It divides the globe into two equal parts, called the eastern and western hemispheres. The quadrant of altitude is a thin pliable plate of brass, answering exactly to a quadrant of the meridian. It is divided into 90°, and has a notch, nut and screw, to fix to the brazen meridian in the zenith of any place, where it turns round a pivot, and supplies the room of vertical circles. The hour-circle is a flat ring of brass, divided into 24 equal parts or hour distances; and on the pole of the globe is fixed an index that turns round with the globe, and points out the hours upon the hour-circle. Lastly, there are generally added a compass and needle upon the pediment of the frame.

The surface of the celestial globe may be esteemed a just representation of the concave expanse of the heavens, notwithstanding its convexity; for it is easy to conceive the eye placed in the centre of the globe, and viewing the stars on its surface. The stars are all disposed in constellations under the forms of various animals, whose names and figures are represented on the celestial globe, which were first invented by the ancient astronomers and poets, and are still retained for the better distinction of these luminaries.

Various improvements have been made in the construction of globes, some of which are of great importance in working the problems; among the latest of these may be mentioned the terrestrial globe of Mr. Christie, which is so mounted as to exhibit the diurnal and annual revolutions of the earth. This globe, while it is made to revolve on its own axis, is moved, by the aid of two parallel levers, round a hollow sphere of ground glass, within which a lamp is placed, and from which a strong light is thrown upon the globe.

As, however, globes mounted either in this way, or on other improved principles, are in the possession of comparatively few persons, the following problems are selected for the use of those who have globes mounted in the common way.

PROBLEMS ON THE TERRESTRIAL GLOBE.

1. *To find the latitude of any place.* Bring the given place to the brazen meridian, and

observe what degree it is under, for that is the latitude required.

2. *To rectify the globe for any given place.* Raise the pole so many degrees above the horizon as are equal to the latitude of the place; then, finding the sun's place, bring it to the meridian; screw the quadrant of altitude on the zenith; set the index of the hour-circle to the upper XII, and place the globe due north and south by the compass.

3. *To find the longitude of a given place.* Bring the place to the brazen meridian, and observe the degree of the equator under the same, for that expresses the longitude required.

4. *To find any place by the latitude and longitude given.* Bring the given degree of longitude to the meridian, and under the given degree of latitude you will see the place required.

5. *To find all those places which have the same latitude or longitude with those of any given place.* Bring the given place to the meridian; then all those places which lie under the meridian have the same longitude: again, turn the globe round on its axis; then all those places which pass under the same degree of the meridian with any given place have the same latitude with it.

6. *To find all those places where it is noon at any given hour of the day in any place.* Bring the given place to the meridian, set the index to the given hour; then turn the globe till the said index points to the upper XII, and observe what places lie under the brass meridian; for to them it is noon at that time.

7. *When it is noon at any one place, to find what hour it is at any other given place.* Bring the first given place to the meridian, and set the index to the upper XII; then turn the globe till the other given place comes to the meridian, and the index will point to the hour required.

8. *For any given hour of the day in the place where you are, to find the hour of the day in any other place.* Bring the place where you are to the meridian, set the index to the given hour, then turn the globe about; and when the other place comes to the meridian, the index will shew the hour of the day there as required.

9. *To find the distance between any two places in English miles.* Bring one place to the meridian, over which fix the quadrant of altitude; and then laying it over the other place, count the number of degrees thereon contained between them; which number multiply by 69½ (the number of miles in one degree,) and the product is the number of English miles required.

10. *To find how any one place bears from another.* Bring one place to the brass meridian, and lay the quadrant of altitude over the other, and it will shew on the horizon the point of the compass on which the latter bears from the former.

11. *To find those places to which the sun is vertical in the torrid zone for any given day.* Find the sun's place in the ecliptic for the given time, and bring it to the meridian, and observe what degree thereof it cuts; then turn the globe about, and all those places which pass under that degree of the meridian, are those required.

12. *To find what day of the year the sun will be vertical in any given place in the torrid zone.* Bring the given place to the meridian, and mark the degree exactly over it; then turn the globe round, and observe the two points of the ecliptic which pass under that degree of the meridian: lastly, see on the wooden horizon on what days of the year the sun is in those points of the ecliptic; for those are the days required.

13. *To find those places in the north frigid zone where the sun begins to shine constantly without setting, on any given day between the 21st of March and the 21st of June.* Find the sun's place in the ecliptic for the given day, bring it to the brazen meridian, and observe the degrees of declination; then all those places which are the same number of degrees distant from the pole are the places required to be found.

14. *To find on what day the sun begins to shine constantly without setting, on any given place in the north frigid zone, and how long.* Rectify the globe to the latitude of the place, and, turning it about, observe what point of the ecliptic between Aries and Cancer, and also between Cancer and Libra, coincides with the north point of the horizon; then find, by the calendar on the horizon, what days the sun will enter those degrees of the ecliptic, and they will solve the problem.

15. *To find the place to which the sun is vertical on any given day and hour.* Find the sun's place, and bring it to the meridian, and mark the degree of declination for the given hour; then find those places which have the sun in the meridian at that time; and among them that which passes under the degree of declination is the place required.

16. *To find, for any given day and hour, those places wherein the sun is then rising and setting, or on the meridian; also those places which are enlightened, and those which are not.* Find the place to which the sun is vertical at the given time, and bring the same to the meridian, and elevate the pole to the latitude of the place. then all those places which are in the western semicircle of the horizon have the sun rising, and those in the eastern semicircle see it setting; and to those under the meridian it is noon. Lastly, all places above the horizon are enlightened, and all below it are in darkness.

17. *The day and hour of a solar or lunar eclipse being given, to find all those places in which the same will be visible.* Find the place to which the sun is vertical at the given instant, and elevate the globe to the latitude of the place; then in most of those places above the horizon will the sun be visible during his eclipse; and all those places below the horizon will see the moon pass through the shadow of the earth in her eclipse.

18. *The length of a degree being given, to find the number of miles in a great circle of the earth, and thence the diameter of the earth.* Admit that one degree contains 69½ English statute miles; then multiply 360 (the number of degrees in a great circle) by 69½, and the product will be 25020, the miles which measure the circumference of the earth. If this number be divided by 3.1416, the quotient will be 7963 $\frac{86}{100}$ miles for the diameter of the earth.

19. *The diameter of the earth being known, to find the surface in square miles, and its solidity in cubic miles.* Admit the diameter to be 7964 miles; then multiply the square of the diameter by 3.1416, and the product will be 199250205 very nearly, which are the

square miles in the surface of the earth. Again, multiply the cube of the diameter by 0.5236, and the product 264466789170 will be the number of the cubic miles in the whole globe of the earth.

20. *To express the velocity of the diurnal motion of the earth.* Since a place in the equator describes a circle of 25020 miles in 24 hours, it is evident, that the velocity with which it moves is at the rate of 1042½ in one hour, or 17$\frac{3}{10}$ miles per minute. The velocity in any parallel of latitude decreases in the proportion of the co-sine of the latitude to the radius.

Thus, for the latitude of London, 51° 30′, say,

As radius.......................................10.000000
To the co-sine of lat. 51° 30′....... 9.794149
So is the velocity in the equator, 17$\frac{3}{10}$′.......................................} 2.238046
To the velocity of the city of London, 10$\frac{8}{10}$′.................................} 2.032195

That is, the city of London moves about the axis of the earth at the rate of 10$\frac{8}{10}$ miles every minute of time: but this is far short of the velocity of the annual motion about the sun; for that is at the rate of more than 65,000 miles per hour.

PROBLEMS ON THE CELESTIAL GLOBE.

1. *To rectify the globe.* Raise or elevate the pole to the latitude of the place; screw the quadrant of altitude in the zenith; set the index of the hour-circle to the upper XII, and place the globe north and south by the compass and needle: then it is a just representation of the heavens for the given day at noon.

2. *To find the sun's place in the ecliptic.* Find the day of the month in the calendar on the horizon, and against it is the degree of the ecliptic which the sun is in for that day.

3. *To find the sun's declination.* Rectify the globe, bring the sun's place in the ecliptic to the meridian, and that degree which it cuts in the meridian is the declination required.

4. *To find the sun's right ascension.* Bring the sun's place to the meridian, and the degree of the equinoctial cut by the meridian is the right ascension required.

5. *To find the sun's amplitude.* Bring the sun's place to the horizon, and the arch of the horizon intercepted between it and the east or west point, is the amplitude, north or south.

6. *To find the sun's amplitude for any given day and hour.* Bring the sun's place to the meridian, set the hour-index to the upper XII; then turn the globe till the index points to the given hour; then screwing the quadrant of altitude in the zenith, lay it over the sun's place, and the arch contained between it and the horizon will give the degrees of altitude required.

7. *To find the sun's azimuth for any hour of the day.* Every thing being done as in the last problem, the arch of the horizon contained between the north point and that where the quadrant of altitude cuts it, is the azimuth east or west as required.

8. *To find the time when the sun rises or sets.* Find the sun's place for the given day, bring it to the meridian, and set the index to XII; then turn the globe till the sun's place touches the east part of the horizon, the index will shew the hour of its rising; turn the globe to the west part of the horizon, and the index will shew the time of its setting for the given day.

9. *To find the length of any given day or night.* This is known by taking the number of hours between the rising and setting of the sun for the length of the day; and the remainder to 24, for the length of the night.

10. *To find the hour of the day, having the sun's altitude given.* Bring the sun's place to the meridian, and set the index to XII; then turn the globe in such a manner, that the sun's place may move along by the quadrant of altitude (fixed in the zenith) till it touches the degree of the given altitude, and the index will shew the hour required.

11. *To find the place of the moon, or any planet, for any given day.* Take White's Ephemeris, and against the given day of the month you will find the degree and minute of the sign which the moon or planet possesses at noon. The degree thus found being marked in the ecliptic on the globe by a small notch or otherwise, you may then proceed to find the declination, right ascension, latitude, longitude, altitude, azimuth, rising, southing, setting, &c. in the same manner as has been shewn for the sun.

12. *To explain the phænomena of the harvest moon.* In order to this we need only consider, that when the sun is in the beginning of Aries, the full moon on that day must be in the beginning of Libra: and since, when the sun sets, or the moon rises on that day, those equinoctial points will be in the horizon, and the ecliptic will then be least of all inclined thereto, the part or arch which the moon describes in one day, viz. 13°, will take up about an hour and a quarter ascending above the horizon; and, therefore, so long will be the time after sun-set, the next night, before the moon will rise. But at the opposite time of the year, when the sun is in the autumnal, and the full-moon in the vernal, equinox, the ecliptic will, when the sun is setting, have the greatest inclination to the horizon; and, therefore 13° will in this case soon ascend, viz. in about a quarter of an hour; and so long after sun-set will the moon rise the next day after the full: whence, at this time of the year, there is much more moonlight than in the spring; and hence this autumnal full moon came to be called the harvest moon, the hunter's or shepherd's moon; all which may be clearly shewn on the globe.

13. *To represent the face of the starry firmament, for any given hour of the night.* Rectify the globe, and turn it about till the index points to the given hour; then will all the upper hemisphere of the globe represent the visible half of the heavens, and all the stars on the globe will be in such situations as exactly correspond to those in the heavens, which may therefore be easily found, as will be shewn in the 16th problem.

14. *To find the hour when any known star will rise, or come upon the meridian.* Rectify the globe and set the index to XII; then turn

the globe till the star comes to the horizon or meridian, and the index will shew the hour required.

15. *To find at what time of the year any given star will be on the meridian at* XII *at night.* Bring the star to the meridian, and observe what degree of the ecliptic is on the north meridian under the horizon; then find in the calendar on the horizon the day of the year against that degree, and it will be the day required.

16. *To find any particular star.* First, find its altitude in the heavens by a quadrant, and the point of the compass it bears on: then, the globe being rectified, and the index turned to he given hour, if the quadrant of altitude is ixed on the zenith, and laid towards the point of the compass on which the star was observed, the star required will be found at the same degree of altitude on the quadrant, as it was by observation in the heavens.

GLOBULAR CHART, a name given to the representation of the surface, or of some part of the surface of the terrestrial globe upon a plane, wherein the parallels of latitude are circles nearly concentric, the meridian curves bending towards the poles, and the romb-lines are also curves.

GLOBULAR SAILING. See SAILING.

GLOBULARIA, *globular blue daisy*, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. There are eight species, but one only is commonly to be met with in our gardens, viz. the vulgaris, or common blue daisy.

GLOW-WORM. See CICINDELA.

GLUCINA, in chemistry, an earth lately discovered by Vauquelin, while he was analyzing the beryl, to ascertain whether its constituent parts were the same as those of the emerald. In this experiment he found the glucina, which he so named from its sweetish taste. Glucina, in the form of powder, or in fragments, is almost three times as heavy as water; it is infusible in the fire; it does not contract, like alumina, by great heat, and it has no effect on vegetable colours. It combines with sulphurated hydrogen. It is insoluble in water, but combines with acids, making with them soluble salts, distinguished by a sweet and slightly astringent taste.

GLUE. An inspissated jelly made from the parings of hides and other offals, by boiling them in water, straining through a wicker basket, suffering the impurities to subside, and then boiling it a second time. The articles should first be digested in lime water, to cleanse them from grease and dirt; then steeped in water, stirring them well from time to time; and lastly laid in a heap, to have the water pressed out, before they are put into the boiler. Some recommend that the water should be kept as nearly as possible to a boiling heat, without suffering it to enter into ebullition. In this state it is poured into flat frames or moulds, then cut into square pieces when congealed, and afterwards dried in a coarse net. It is said to improve by age; and that glue is reckoned the best, which swells considerably without dissolving by three or four days' infusion in cold water, and recovers its former dimensions and properties by drying.

Shreds or parings of vellum, parchment, or white leather, make a clear and almost colourless glue.

GLUTEN. If wheat flour be made into a paste, and washed in a large quantity of water, it is separated into three distinct substances: a mucilaginous saccharine matter, which is readily dissolved in the liquor, and may be separated from it by evaporation; starch, which is suspended in the fluid, and subsides to the bottom by repose; and gluten, which remains in the hand, and is tenacious, very ductile, somewhat elastic, and of a brown-grey colour. The first of these substances does not essentially differ from other saccharine mucilages. The second, namely the starch, forms a gluey fluid by boiling in water, though it is scarcely, if at all, acted upon by that fluid when cold. Its habitudes and products with the fire, or with nitric acid, are nearly the same as those of gum and of sugar. It appears to be as much more remote from the saline state than gum, as gum is more remote from that state than sugar.

The vegetable gluten, though it existed before the washing in the pulverulent form, and has acquired its tenacity and adhesive qualities from the water it has imbibed, is nevertheless totally insoluble in this fluid. It has scarcely any taste. When dry, it is semitransparent, and resembles glue in its colour and appearance. If it be drawn out thin, when first obtained, it may be dried by exposure to the air; but if it be exposed to warmth and moisture while wet, it putrefies like an animal substance. The dried gluten applied to the flame of a candle, crackles, swells, and burns, exactly like a feather, or piece of horn. It affords the same products by destructive distillation as animal matters do; is not soluble in alcohol, oils, or ether; and is acted upon by acids, and alkalis, when heated. According to Rouelle, it is the same with the caseous substance of milk.

GLYCYRRHIZA, or *liquorice*, a genus of the diadelphia decandria class and order. Natural order of papilionaceæ or leguminosæ. There are four species. These are tall growing perennial, herbaceous plants, with the stalks somewhat woody at bottom. Stipules are distinct from the petiole; flowers in a head or spike from the axils and at the ends of the branches; seed vessel a legume or pod, smooth, hairy, or prickly. Their propagation is effected by cuttings of the small roots. An open situation and a deep loose soil is the most suitable for them. In three years the roots will be fit to take up. Liquorice is almost the only sweet that quenches thirst, and has been employed in hydropic cases, to prevent the necessity of drinking. An extract is made from the root.

GLYPH, in sculpture and architecture, denotes any canal or cavity, used as an ornament.

GMELINA, in botany, so called in honour of Joh. George Gmelin, professor of natural history at St. Petersburgh, afterwards of Botany at Tubingen, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is nearly quadridentated; the corolla campanulated or bell-shaped; there are two bipartite and two simple antheræ; the fruit is a plum with a bilocular kernel. There is one species, a tree of Malabar.

GNEISS. A compound rock, consisting of felspar, quartz, and mica, disposed in slates, from the predominance of the mica scales. Its structure is called by Werner, granular-slaty. This geognostic formation is always stratified; contains sometimes crystals of schorl, tourmaline, and garnet, and is peculiarly rich in metallic ores.

GNOMON, in dialling, the style, pin, or cock of a dial, which by its shadow shews the hour of the day. The gnomon of every dial represents the axis of the world. See DIAL and DIALLING.

GNOSTICS, in church history, Christians so called, it being a name which almost all the ancient heretics affected to take to express that new knowledge and extraordinary light to which they made pretensions; the word gnostic signifying a learned or enlightened person.

GOAT. See CAPRA.

GOAT *sucker.* See CAPRIMULGUS. These birds are regarded by the American Indians as very ominous. They believe that goat-suckers were not known in their country till the English had made depredation upon it, and that they are, in fact, the departed spirits of the murdered Indians. In Carolina the lower class of people look upon them as birds of ill omen, and are gloomy and almost melancholy if one alights on the house or near the door, and begins its call, which they will sometimes do, even on the very threshold, imagining that it is a sure prognostic of the death of one of the family.

GOBIUS, the *goby,* in natural history, a genus of fishes of the order Thoracici. Generic character; head small; eyes approximated, with two punctures between them; gill membrane, four-rayed; ventral fins, united into a funnel-like oval; dorsal fins two. There are twenty-five species.

GOD, *Deus,* the Supreme Being, the first cause or creator of the universe, and consequently, the only proper object of religious worship. There cannot possibly be any subject respecting which it is of such importance for human beings to form correct notions as this. Many truly able, and pious arguments have been produced in favour of the existence of God, but it cannot be denied that while those arguments produce their full effect on the mind as to the fact itself, they, in general, leave it in a state of great perplexity, amounting almost to distraction, as to what *definite* idea should be entertained of the GREAT SUPREME. It is true that a question of such moment ought to be approached by finite creatures with the most profound reverence; yet if it is true that the grand object of Divine Revelation is to communicate to man the true knowledge of his Maker, it cannot be deemed presumption to infer that, in that divinely inspired volume, there is such a sufficiency of information afforded as shall form for the most anxious mind a suitable resting place.

The grand defect to which we here allude is the vague manner in which philosophers and theologians have treated the subject of the divine existence. This has arisen from the difficulty of elevating the mind to the contemplation of God as existing in a definite form, yet totally independent of the limits of time and space. That acute reasoner, Dr. Priestley, in his Essays on Matter and Spirit, evidently evinces that he conceives of God as subject to extension, as having properties in common with matter, as bearing relation to space, and, in one word, as being himself absolutely *material,* and having nothing of immateriality about him. From this it is very obvious that the Doctor, if he allow the Divine Being to possess any form at all, must admit that that form is the form assumed by infinite space, which is acknowledging that the Deity exists in the form of an infinitely extended sphere, an idea unworthy of a moment's serious consideration.

Now, it is a striking fact, to which every man's experience will bear witness, that until the mind is sophisticated by reasonings on the subject, it never thinks of God as existing in any other than the human form. And whence arises this universal impression? Doubtless from these two very obvious, though but little attended to circumstances. 1. That throughout the innumerable and endlessly varied objects of the visible creation, there is, more nearly or remotely, a tendency to the human form; and we are well assured that man himself was originally created an image and likeness of his Maker. 2. That throughout the whole of divine revelation where any intimation is given of the appearance of the Deity, (and instances of this are numerous,) it was always in the human form. And let it be particularly remembered, that all those appearances had a direct bearing upon his final manifestation upon earth for the redemption and salvation of mankind, which no one will deny was also in the human form. And after this most wonderful event was accomplished, still he appeared in the proper form of man; in this form he was seen when encircled with all the glory of the celestial world; and the plainest intimations are given in Scripture, that throughout eternity he will never be beheld in any other.

GOLD. See CHEMISTRY.

GOLD *leaf.* The method of extending gold used by the gold-beaters, consists in hammering a number of thin rolled plates between skins or animal membranes. By the weight and measure of the best wrought gold leaf, it is found, that one grain is made to cover 56¾ square inches; and from the specific gravity of the metal, together with this admeasurement, it follows, that the leaf itself is $\frac{1}{282000}$ part of an inch thick. This, however, is not the limit of the malleability of gold; for the gold-beaters find it necessary to add three grains of copper in the ounce to harden the gold, which otherwise would pass round the irregularities of the newest skins, and not over them; and in using the old skins, which are not so perfect and smooth, they proceed so far as to add twelve grains.

GOLD *wire.* The wire which is used by the lace-makers, is drawn from an ingot of silver, previously gilded. In this way, from the known diameter of the wire, or breadth when flattened, and its length, together with the quantity of gold used, it is found, by computation, that the covering of gold is only one 12th part of the thickness of gold-leaf, though it still is so perfect as to exhibit no cracks when viewed by a microscope.

GOLD *potable.* Ether, naphtha, and essential oils, take gold from its solvent, and form liquors, which have been called potable gold

The gold which is precipitated by evaporation of these fluids, or by the addition of sulphate of iron to the solution of gold, is of the utmost purity.

Gold *fulminating*. See Chemistry.

Gold, *shell*, that used by the illuminers to write gold letters, is made with the parings of leaf-gold, and even of the leaves themselves, reduced into an impalpable powder, by grinding on a marble with honey. After leaving it to infuse some time in aquafortis, they put it in shells, where it sticks. To use it, they dilute it with gum-water, or soap-water.

GOLDFINCH. See Fringilla.

GOLDSMITH, or silversmith, an artist who makes vessels, utensils, and ornaments, in gold and silver.

The goldsmith's work is either performed in the mould, or beaten out with the hammer, or other engine. All works that have raised figures are cast in a mould, and afterwards polished and finished: plates or dishes of silver or gold are beaten out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates soldered together, and their mouldings are beaten, not cast.

GOLDEN *number*, a number shewing what year of the moon's cycle any year is.

GONDOLA, in naval architecture, a flat kind of boat, very long and narrow, chiefly used on the canals at Venice.

GONG, in music, an instrument used in China, is made of a metal composed of silver, lead, and copper, and its shape is a sort of circular concave. The tone is loud, harsh, and clanging. It is never introduced except on occasion of giving a national cast to the music in which it is employed, or to awaken surprize, and rouse the attention of the company.

GONIOMETER. The instrument for measuring the angles of crystals is called a goniometer, of which there are two kinds. 1. The goniometer of M. Carangeau, used by M. Haüy, consists of two parallel blades, jointed like those of scissars, and capable of being applied to a graduated semicircular sector, which gives the angle to which the joint is opened, in consequence of the previous apposition of the two blades to the angle of the crystal. 2. The reflective goniometer of Dr. Wollaston; an admirable invention, which measures the angles of the minutest possible crystals with the utmost precision. To these we may add another invented by Dr. Brewster, and described in the Edinburgh Encyclopædia, Vol. 10. It is much the same as that of Dr. Wollaston, but differs in the application of the principle of construction, and is capable of measuring a hollow angle.

GONIUM, a genus of vermes, of the order infusoria. Worm very simple, flat, angular, invisible to the naked eye. There are five species. The pectoral, quadrangular, pellucid, with 16 spherical molecules, found in pure water; molecules oval, nearly equal in size, set in a quadrangular membrane, like diamonds in a ring, the lower ones a little larger than the rest.

GOOSE. See Anas.

Goose *berry*. See Ribes.

Goose *neck*, in a ship, a piece of iron fixed on the end of the tiller, to which the laniard of the whip-staff, or the wheel rope comes for steering the ship

Goose *wing*, in the sea-language. When a ship sails before, or with, a quarter-wind on a fresh gale, to make the more haste, they launch out a boom, and sail on the lee-side; and a sail so fitted, is called a goose-wing.

GORDIUS, in natural history, *hair-worm*, a genus of the vermes intestina class and order. Body round, filiform, equal, smooth. There are five species. G. aquaticus is from four to six inches long, of a pale brown colour, but darker at the extremities: it is found in stagnant waters, and twists itself into various contortions and knots, and it is said that if it is handled without caution, it will inflict a bite that occasions the whitlow.

GORGONIA, in natural history, a genus of the vermes zoophyta class and order. Animal growing in the form of a plant; stem coriaceous, corky, woody, horny, or bony, composed of glassy fibres, or like stone, striate, tapering, dilated at the base, covered with a vascular or cellular flesh or bark, and becoming spongy and friable when dry; mouths or florets covering the surface of the stem and polype bearing. There are about forty species.

GOSHAWK. See Falco.

GOSSAMER, is the name of a fine filmy substance, like cobweb, which is seen to float in the air in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is probably formed by the flying spider, which, in traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSSYPIUM, or cotton; a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is double, the exterior one trifid; the capsule quadrilocular; the seeds wrapt in cotton-wool. There are six species, all of them natives of warm climates. 1. The herbaceum, or common herbaceous cotton, has an herbaceous smooth stalk two feet high, branching upwards; five-lobed smooth leaves; and yellow flowers from the ends of the branches, succeeded by roundish capsules full of seed and cotton. 2. The hirsutum, or hairy American cotton, has hairy stalks branching laterally two or three feet high; palmated, three and five-lobed hairy leaves; and yellow flowers, succeeded by large oval pods furnished with seeds and cotton. 3. The barbadense, or Barbadoes shrubby cotton, has a shrubby stalk branching four or five feet high, three lobed smooth leaves, glandulous underneath: and yellow flowers succeeded by oval pods, containing seeds and cotton. 4. The arboreum, or tree cotton, has an upright woody perennial stalk, branching six or eight feet high; palmated, four or five-lobed smooth leaves, and yellow flowers, succeeded by large pods filled with seeds and cotton. The first three species are annual, but the fourth is perennial both in root and stalk. In warm countries these plants are cultivated in great quantities in the fields for the sake of the cotton they produce; but the first species is most generally cultivated. The pods are sometimes as large as middling-sized apples, closely filled with the cotton surrounding the seed.

GOTHIC *style*, in architecture. The characteristics of this manner of building are pointed arches, greater height than breadth in the proportions, and profuse ornament chiefly derived

from an imitation of the leaves and flowers of plants.

GOVERNMENT, in general, is the polity of a state, or an orderly power constituted for the public good.

Civil government was instituted for the preservation and advancement of men's civil interests, and for the better security of their lives, liberties, and properties. The use and necessity of government is such, that there never was an age or country without some sort of civil authority; but as men are seldom unanimous in the means of attaining their ends, so their difference in opinion, in relation to government, has produced a variety of forms of it. To enumerate them would be to recapitulate the history of the whole earth. But they may, in general, be reduced to one of these heads; either the civil authority is delegated to one or more, or else it is still reserved to the whole body of the people; whence arises the known distinction of government into monarchy, aristocracy, and democracy.

The government of this country is unquestionably a mixed government, though by some writers it is denominated a limited monarchy. It is formed by a combination of the three regular species of government; the monarchy residing in the King, the aristocracy in the House of Peers, and the republic, being represented by the House of Commons.

GOUGE, an instrument or tool used by divers artificers; being a sort of round hollow chissel, for cutting holes, channels, grooves, &c. either in wood or stone.

GOURD. See CUCURBITA.

GOUT. See MEDICINE.

GRACE, *act of*, an act of parliament for a general and free pardon, and for setting at liberty insolvent debtors.

GRACE, *days of*, in commerce. See BILLS OF EXCHANGE.

GRACULA, the *grakle*, in natural history, a genus of birds of the order Picæ. Generic character: the bill convex, thick, sharp-edged, somewhat naked at the base; nostrils small, near the base of the bill; tongue entire, rather sharp at the end; claws hooked and sharp. No species of this bird is found in Europe. There are thirteen species, of which the following are the most remarkable: Gracula kelegiosa, or the minor grakle, is of the size of a blackbird, is found in various districts of the East Indies, and almost in every island beyond the Ganges. It is rendered familiar with the greatest ease, and readily taught to speak. The paradisœa tristis is rather larger than the former, and inhabits the Philippine islands.

Graculus quiscular, or purple grakle inhabits Carolina and other parts of North America, and is found also in the island of Jamaica, where it frequently makes great devastation in the maize fields. It is however found highly serviceable in devouring insects.

GRADUATE, a person who has taken a degree in the university.

GRADUATION, in mathematics, the act of graduating or dividing any thing into degrees, or equal parts.

GRAFTING, in gardening, is the insertion of a scion into a stock or stem raised for the purpose, and is necessary to the ensuring of good fruit, *i. e.* to have the same produced on the new tree, as that of the old one whence the graft was taken: it is sometimes performed on the branches of trees, and may be on the roots, a piece being raised out of the ground for the purpose.

The first thing to be done is, to cut off the head of the stock at the proper height, and in a fair part of the bark, making a smooth flat top. The most proper size for stocks, is from half an inch to an inch diameter.

Dwarf trees are to be grafted within six inches of the ground, and standards as high as the stock will well bear, considering whether they are to be half or full standards.

The scions should be healthy and strong, and taken from the outsides of fruitful trees, where the juices of the wood have been properly digested by sun and air; they should be taken from trees just in their prime, or at full bearing, and not before. Let them be cut two or three weeks sooner than wanted. The middle of scions are fittest for the purpose; but do not cut off the tops till they are brought out to graft, for they keep best in length. Take off a little of the lower end of the scion first, and then cut it in length, so as to have three or four eyes to appear above the claying: two eyes will be sufficient for a standard, but four are better for a dwarf that is to be trained.

The time for grafting is usually from mid-February to mid-March; but in a forward season sooner, and in a backward one sometimes later.

Cleft-grafting has been the most common method of propagation. The stocks for this mode of grafting should be strong, about three quarters of an inch diameter, or more; but it may be used with very young stocks, having scions of like thickness.

Cut off the head, as before directed, so as to have (on the sunny side) a smooth part in the stock, where the scion is to be placed, and cutting a part of the stock off slopewise, opposite to this place, leave the top or the crown of the stock, about the distance of half an inch wide. Then cleave the stock with a strong knife, or thin sharp chisel, about two inches deep, as near the middle as possible, so as not to divide the pith, and if any roughness appears in the slit, smooth it off with a penknife; but something of the wedge kind must be put into the slit to keep it open to receive the scion, leaving proper room to put it in. Cut the scion on each side to the form of a wedge at bottom, an inch or more long, making that side which is to be placed inwards in the stock, thinner by about one third. Put the scion in, so that its bark and that of the stock may be level, and consequently that the two barks may unite and run into each other; for on this one principle depends the whole art of grafting.

The graft must be nicely whipped round with wet bass pulled tight, and the whole clayed over to an inch above and half an inch below, smoothing it off taper, with a trowel or knife dipped in water.

Whip-grafting has the advantage of cleft-grafting in neatness, and not requiring the stocks to be so old by a year or two, as very small ones will do in this way; for the stock is directly covered by the scion, and it takes with certainty if properly performed.

Having cut the head of the stock off, and the scion to its proper length, slope the lower end of the scion about an inch and a half, and

to a point; then cut the stock to answer it. bark against bark, and tie them together exactly to their place, and clay it.

Grafting in the bark, or *crown-grafting*, is perhaps as good a way as any, both for ease of operation and certainty of success; but it will hardly suit any other fruit than apples or pears. The head being cut off, make a straight slit down through the bark from the top, at the place destined for the graft, nearly as long as the slope cut of the scion, which may be one and a half or two inches. Loosen the bark a little at the top of the score, and then with some smooth instrument open the bark sufficiently to receive the scion. This instrument should be thin, tapered and rounded towards the point, to suit the shape of the scion's face, one side of it flat, and the other a little convex, the flat side being applied to the wood of the stock; let it be rather narrower than the scion, that it may not loosen the bark too widely.

Cut a bit of the bark of the scion smooth off at the bottom that it may not turn up in pushing down. It will be proper to cut the scion with a small shoulder, to rest upon the stock. And because when the scion is in, it will bear the bark up hollow from the stock, score the bark each side the scion, so that it may fall close to the stock, and to the edges of the scion. Bind and clay neatly.

This way of grafting is used most properly with strong stocks; and sometimes is applied to large branches, and even trunks of old trees to change the sorts or renew the wood.

Side-grafting is done in the bark, much like inoculation, a scion being inserted instead of a bud; but remember, there must be a fluent sap first, i.e. the bark must part readily from the wood, before this mode of grafting is attempted. The head of the stock is not to be cut off, only thinned a little if it is large, and the side shoots taken away. The bark of the stock, where the insertion of the scion is to be, must be cut through in the form of the letter T, as wide and as long as is sufficient to receive the scion, cut as before, with a slope face of at least an inch long, taking advantage of a part of the stock that is a little gibbous. Let the bark of the stock be neatly raised to receive it, but yet no more than necessary; a little bit of the bark may be sliced off the part that is over the cross cut, to receive the scion the better.

Approach-grafting or *inarching*, is performed in April or May. When the stock we would graft, and the tree we would propagate, grow near together, bend the best situated young branch of the tree or shrub to be propagated, to the stock to be grafted, and having determined on the part at which most conveniently to fix the shoot, cut the bark of that part of the shoot off, with nearly half the wood (not to touch the pith) to the length of about three inches for a strong branch, or less for a weaker. Then cut exactly so much of the bark and branch of the stock off, as will receive the cut part of the branch or shoot, so as to bring bark and bark in contact in every part; and if the contrivance of lipping is used, it will secure them better together. Bind and clay, and if in open ground, fix a stake to tie the work so that the wind may have no power over it.

Budding or *inoculation*, though here last mentioned, is the most considerable mode of propagation.

Inoculation may be performed as soon as good shoots with good eyes of the present year can be had, so that the season may be reckoned from mid June to mid-August. Peaches and nectarines are propagated on plum-stocks. Plums and cherries may be inoculated on sucker stocks of any kind; but stocks raised from stones are best. Pears, if for standards, should be inoculated on pear stocks, and on those raised from seed, rather than suckers; but if for dwarfs, quince stocks may be best used, to keep the trees from growing off too fast.

Let the scions to procure buds for inoculation, be taken only from the outside branches of healthy and fruitful trees; but they must not be taken from the upper part of the scions, as the bark and buds there are too raw.

Before the buds are prepared, get the stock ready to receive them, by taking off lateral shoots, leaving an uncut single stem. At the part fixed on for the inoculation (which should be smooth, and rather on the north side) cut the bark through to the wood in the form of a T, the cross and the down slit being of the length necessary to take in the bud, which may be cut with from one to two inches of bark; putting the point of a knife (or some instrument rather not of iron or steel) into the top of the down cut of the stock, raise the bark all the way to the bottom, so that it will just receive the bud easily. There are knives made on purpose for budding, with flat ivory hafts.

To procure proper buds, put the knife in (suppose) about three-fourths of an inch above the eye, and with a slope downwards cut the scion half through, then do it at the same distance below the eye, and sloping it upwards cut up the middle of the wood, till the knife meets the upper incision, so the eye, or bud, will be directly in the middle.

Separate the wood from the bark, which is to be done thus: with your nail, or the point of a knife, loosen the bark at the top, and strip it from the wood; or rather with a swan or large goose quill, made in the form of an apple-scoop (having a regular smooth edge) push it down between the bark and wood, pressing it against the wood.

Examine the inside of the bark, and if there is a cavity just behind the eye or bud, it is good for nothing, and another must be procured.

The leaf that grows by the eye is to be cut down to near its footstalk, so as to leave only a little bit of it to hold the bud by.

See that the bark of the stock is loosened a proper length and breadth, and if, when the bud is put in, it should prove a little too long, cut the spare part off; so that the top of the bud being squared, falls in straight with the cross cut of the stock. Thus fixed, bind it moderately tight in its place, with the wet bass, beginning at the bottom, and passing by the bud, go on to the top, or rather above it. Care must be taken that the bud be not hurt, and it is to be left only just starting out between the bass.

If the buds have taken, it will be seen in about three weeks or a month, by their ap-

pearing fresh and plump. As often as any shoots appear below the budding, cut them off, and also some of the shoots above, if there are many of them: for it is not proper that an inoculated stock should have a large head. In a month loosen the bandage, by taking it off, and putting it on gently again for another month.

In March, cut the head of the stock off with a keen knife, close behind the budding, in a sloping direction. Suffer no shoots from the stock, but rub the buds off as soon as they appear. It may be of use to shade inoculated buds a few days by a leaf, or a bit of paper.

GRAIN, a small weight, the twentieth part of a scruple in apothecaries' weight, and the twenty-fourth of a pennyweight troy.

Grain also denotes the component particles of stones and metals, the veins of wood, &c Hence cross-grained, or against the grain, is contrary to the fibres of wood, &c.

GRAMMAR, may be defined to be the art of speaking or of writing any language with propriety. The term is commonly applied to a collection of observations called *rules*, to which the methods of speaking used in that language to which they belong may be reduced. For the sake of distinctness, writers on grammar usually divide the subject into four distinct heads, viz. *Orthography*, or the art of combining letters into syllables, and syllables into words; *Etymology*, or the art of deducing one word from another, and the various modifications by which the sense of any one word can be diversified consistently with its original meaning, or its relation to the theme whence it is derived; *Syntax*, which relates to the construction or right disposition of words into sentences or phrases; and *Prosody*, which treats of the quantities and accents of syllables, and the art of making verses.

To give even a general view of the grammar of our own language would far exceed our limits; nor, indeed, is any thing of this kind requisite, since the truly excellent works of Murray on the subject are in the hands of every student of English: to those, however, who are desirous of acquiring a thorough knowledge of that language, a careful perusal of that curious and entertaining work, "Tooke's Diversions of Purley," is indispensable.

GRAMME, in French weights. The unit weight, called a gramme, is the weight of the cube of the hundredth part of the metre of distilled water, taken at its maximum density. It answers to 15.444 grains.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerable time.

GRANATITE, *cross stone*, a mineral found in Spain, and in some parts of France and Switzerland. It is crystallized in a very peculiar form; two six-sided prisms intersect each other at right angles, or obliquely. Hence its name, cross stone. It is of a reddish brown colour; specific gravity 3.3, nearly. It is fusible before the blow-pipe.

GRAND *jury*, is the jury which find bills of indictment before justices of peace and gaol-delivery, or of oyer and terminer, &c. against any offenders that may be tried for the fact. See Jury.

GRANITE. A compound rock, consisting of quartz, felspar, and mica, each crystallized and cohering by mutual affinity, without any basis or cement. The felspar commonly predominates, and the mica is in smallest quantity. The colours of the felspar are white, red, grey, and green. The quartz is light grey, and the mica dark. The granular crystals vary exceedingly in size, in different granite rocks. Occasionally granite is stratified: but sometimes no stratification can be perceived. Large globular masses, called rolling stones, are frequently met with, composed each of concentric lamellar concretions. Schorl, garnet, and tinstone, are frequently present in granite. Tin and iron are the only metals abundantly found in this rock. It contains molybdena, silver, copper, lead, bismuth, arsenic, titanium, tungsten, and cobalt. It is, however, poorer in ores than many other rock formations.

GRANT, in law, a gift in writing of such a thing as cannot be passed or conveyed by word only, as a grant is the regular method, by the common law, of transferring the property of incorporeal hereditaments, on such thing whereof no livery of seisn can be had. For which reason, all corporeal hereditaments, as lands and houses, are said to be in livery; and the others, as advowsons, commons, services, rents, reversions, and the like, lie in grant. He that granteth is termed the grantor; and he to whom the grant is made is termed the grantee. A grant differs from a gift in this; that gifts are always gratuitous, grants are upon some consideration or equivalent. The operative words in grants are *dedi et concessi*, "I have given and granted." Grants may be void by incertainty, impossibility, being against law, or a wrong title, to defraud creditors, &c.

GRANULATION, the method of dividing metallic substances into grains or small particles, in order to facilitate their combination with other substances, and sometimes for the purpose of readily subdividing them by weight.

This is done either by pouring the melted metal into water, or by agitating it in a box until the moment of congelation, at which instant it becomes converted into a powder.

Various contrivances are used to prevent danger, and ensure success, in the several manufactories that require granulation. Copper is granulated for making brass, by pouring it through a perforated ladle into a covered vessel of water with a moveable false bottom. A compound metal, consisting chiefly of lead, is poured into water through a perforated vessel of another kind, for making small shot, in which the height above the surface of the fluid requires particular adjustment. In a new manufactory of this kind, the height is upward of 100 feet.

GRAPE. See Vitis.

Grape-*shot*, in artillery, a combination of small shot, put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder.

GRAPHITE, *Blacklead*, or *Plumbago*. See Plumbago.

GRAPHOMETER, is a name sometimes given to mathematical instruments similar to goniometers, or to particular modifications of the theodolite.

GRASS. For the culture of the different grasses. See AGRICULTURE.

GRASSHOPPER, in zoology. See GRYLLUS.

GRATIOLA, *hedge-hyssop,* a genus of the monogynia order, in the diandria class of plants. There are 12 species; the most remarkable of which is the officinalis, or common hedge-hyssop. This grows naturally in the Alps and other mountainous parts of Europe.

GRAVE, in music, is applied to a sound which is of a low or deep tone. The thicker the cord or string, the more grave is the note or tone: and the smaller, the more acute. The gravity of sounds depends on the slowness of the vibratory motions of the chord; and their acuteness on its quick vibrations.

GRAVE *accent,* in grammar, shews that the voice is to be lowered; its mark stands thus `.

GRAVE *digging beetle.* See SILPHA.

GRAVEL, in natural history and gardening, a congeries of pebbles, which, mixed with a stiff loam, makes lasting and elegant walks; an ornament peculiar to our gardens, and which gives them the advantage over those of other nations.

GRAVER, in the art of engraving, a tool by which all the lines, scratches, and shades, are cut in copper, &c.

GRAVIMETER. See HYDROMETER.

GRAVITATION. See ASTRONOMY.

GRAVITY *Specific.* See SPECIFIC GRAVITY.

GREAT-*circle sailing,* the manner of conducting a ship in, or rather pretty near, the arch of a great circle, that passes through the zenith of the two places, viz. whence she came, and to which she is bound.

GREEK *fire,* an invention of the middle ages, which enabled the Greeks for a time to resist the arms of the Mahometans. Asphaltum is supposed to have been its chief constituent, along with nitre and sulphur.

GREEN, one of the original colours excited by the rays of light. The green colour of plants has been shown, by the French chemists, to depend upon the absorption of carbonic acid, and it is supposed that the leaves of plants have the power of decomposing the carbonic acid and water also.

GREEN, *Brunswick.* It is made by saturating cold water with muriated ammonia, and adding three times as much copper clipping as ammonia. The moisture is to be evaporated, taking care that no dust be allowed to get to it. The muriate of ammonia is decomposed by the copper, which is itself corroded and converted into a green oxide. It is then to be digested in successive portions of alcohol, as long as any green oxide is taken up; the solutions are now to be added together, and the liquor to be driven off by a moderate heat; the residue is the pigment required.

GREEN *cloth,* a board or court of justice, held in the counting-house of the king's household, composed of the lord steward, and officers under him, who sit daily. To this court is committed the charge and oversight of the king's household in matters of justice and government, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiction of the court royal; which is every way about two hundred yards from the last gate of the palace where his Majesty resides. Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

GREEN-*finch.* See FRINGILLA.

GREEN-*house,* or conservatory, a house in a garden contrived for sheltering and preserving the most tender and curious exotic plants, which, in our climate, will not bear to be exposed to the open air during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

GREGORIAN *calendar,* that which shews the new and full moon, with the time of Easter, and the moveable feasts depending thereon, by means of epacts, disposed through the several months of the Gregorian year.

GREGORIAN *epoch,* the epocha, or time whence the Gregorian calendar or computation took place. The year 1808 is the 226th year of that epocha.

GREGORIAN *year,* the Julian year corrected, or modelled, in such a manner as that three secular years, which in the Julian account are bissextile, are here common years, and only every fourth secular year is made a bissextile year.

The Julian computation is more than the solar year by eleven minutes, which in one hundred and thirty-one years amounts to a whole day. By this calculation, the vernal equinox was anticipated ten days from the time of the general council of Nice, held in the year 325 of the Christian æra, to the time of Pope Gregory XIII. who therefore caused ten days to be taken out of the month of October, in 1582, to make the equinox fall on the twenty-first of March, as it did at the time of that council, and to prevent the like variation for the future, he ordered that three days should be abated in every four hundred years, by reducing the leap-year at the close of each century for three successive centuries to common years, and retaining the leap-year at the close of each fourth century only. This was at that time esteemed as exactly conformable to the true solar year, but is is found not to be strictly just, because in 400 years it gets one hour and twenty minutes.

GREYWACKE. A mountain formation, consisting of two similar rocks, which alternate with, and pass into each other, called greywacke, and greywacke-slate. The first possesses the characters of the formation. It is a rock composed of pieces of quartz, flinty-slate, felspar, and clay-slate, cemented by a clay-slate basis. These pieces vary in size from a hen's egg to little grains. When the texture becomes exceedingly fine grained, the rock constitutes greywacke-slate. Its colour is usually ash or smoke-grey, without the yellowish-grey, or greenish tinge, frequent in primitive slate. It has not the continuous lustre of primitive slate, but glimmers from interspersed scales of mica. It contains quartz veins, but no beds of quartz. Petrefactions are found in it.

GRIFFON, in heraldry, an imaginary animal, feigned by the ancients to be half eagle and half lion; by this form they intended to give an idea of strength and swiftness joined

together, with an extraordinary vigilance in guarding the things entrusted to its care.

GRINDING, *trituratio*, the reducing hard substances to fine powders, either by the mortar, or by way of levigation, upon a marble.

GRISLEA, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. There are two species; one a tree of South America, the other a shrub of the East Indies.

GRIST, in country-affairs, denotes corn ground, or ready for grinding.

GRIT, a genus of argillaceous earths. Its texture is more or less porous, equable, and rough to the touch. It does not give fire with steel, nor effervesce with acids. When fresh broken and breathed upon, it exhales an earthy smell.

GROSS, in law-books, signifies absolute or independent on another: thus, an advowson in gross, is one distinct and separate from the manor.

GROSS-*beak*, in ornithology. See LOXIA.

GROSS-*weight*, the whole weight of merchandizes, with their dust and dross; as also the bag or chest wherein they are contained. An allowance is usually made out of the gross-weight for tare and tret. See TARE.

GROTESQUE, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature, or of things so distorted, as to raise surprize and ridicule.

GROTTO, a large deep cavern or den in a mountain or rock. The word is Italian, grotta; formed from the Latin crypta. The ancient anchorites retired into dens and grottos, to apply themselves the more attentively to meditation. Okey-hole, Elden-hound, Peake's-hole, and Pool's-hole, are famous among the natural caverns or grottos of our country.

The *Grotto del Cano*, situated about two miles from Naples, is celebrated for the noxious nature of the air contained in it, which is in fact carbonic acid gas. As this gas, from its weight, must always lie along the bottom of the cavern, small animals on entering must breathe it; whereas a man may traverse it in safety, as his head is considerably above the pestilential vapour. The height to which the gas rises may be seen from observing the colour of the sides of the cavern.

GROUND, in painting, the surface upon which the figures and other objects are represented. See PAINTING.

GROUP, in painting and sculpture, is an assemblage of two or more figures of men, beast, fruits, or the like, which have some apparent relation to each other.

GRUB, the name of worms produced from the eggs of beetles, which are at length transformed into winged insects of the same species with their parents.

GROUSE, a species of the TETRAO, which see.

GRUINALES, in botany, the name of the fourteenth order of Linnæus's Fragments. This order furnishes both herbaceous and woody plants. The roots are sometimes fibrous, and sometimes tuberous. In some species of the oxalis, wood sorrel, they are jointed; the stems are cylindric, and the young branches in some nearly square; the buds are of a conic form, covered with scales; the leaves in some genera are simple, in others compound; the flowers are hermaphrodite. In this order are the geranium, crane's-bill; linum, flax; oxalis, wood-sorrel; guiacum, lignum-vitæ.

GRUS, the *crane*. See ARDEA.

GRYLLUS, in natural history, the *locust*, *grasshopper*, and *cricket*, a genus of insects belonging to the order hemiptera. Generic character: head inflected, armed with jaws, and furnished with feelers: antenna, in most species, either filiform or setaceous; wings four, deflex, convoluted: lower wings plaited; hind legs formed for leaping; claws double on all the feet. There are sixty-one species.

Among the most numerous species is the gryllus migratorius of Linnæus, or common migratory locust. Legions of these animals are from time to time observed in various parts of the world, where the havock they commit is almost incredible: whole provinces are in a manner desolated by them in the space of a few days, and the air is darkened by their numbers: nay, even when dead, they are still terrible; since the putrefaction arising from their inconceivable number is such, that it has been regarded as one of the probable causes of pestilence in the eastern regions.

One of the largest species of locust yet known is the *grillus cristatus* of Linnæus, which is five or six times the size of the gryllus migratorius; and, together with some others of the larger kind, is made use of in various parts of the world as an article of food.

The *gryllus viridissimus* of Linnæus is one of the largest European species, and is often seen during the decline of summer in our own country.

The *gryllus gryllotalpa*, or mole-cricket, is the most curious; and in its colour and manners differs greatly from the rest. It is of an uncouth and even formidable aspect, measuring more than two inches in length, its fore-legs are furnished with very broad feet, divided into several sharp claw-shaped segments, with which it is enabled to burrow under ground; it emerges from its subterraneous retreats only by night, when it creeps about the surface, and occasionally employs its wings in flight. The mole-cricket lives entirely on vegetables, devouring the young roots of grasses, &c. and commits great devastation in gardens.

G. *tettigonia* or grasshopper, well known in our meadows, and the *acheta* or hearth cricket, belong to this genus.

GUAIACUM. A resinous looking substance, extracted from the very dense wood of a tree growing in the West Indies, called *guaiacum officinale*. It differs however from resins in its habitudes with nitric acid, as Mr. Hatchett first shewed. Its specific gravity is 1.229. Its colour is yellowish-brown, but it becomes green on exposure to light. It is transparent, and breaks with a resinous fracture. Its odour is not disagreeable, but when a very little of its powder, mixed with water, is swallowed, it excites a very unpleasant burning sensation in the fauces and stomach. Heat fuses it, with the exhalation of a somewhat fragrant smell. Water dissolves a certain portion of it, acquiring a brownish tinge, and sweetish taste. The soluble matter is left when the water is

evaporated. It constitutes 9 per cent of the whole, and resembles what some chemists call extractive.

Guaiacum is very soluble in alcohol. This solution, which is brown-coloured, is decomposed by water. Aqueous chlorine throws down a pale blue precipitate from it.

Guaiacum dissolves readily in alkaline leys, and in sulphuric acid; and in the nitric with effervescence. From the solution in the last liquid, oxalic acid may be procured by evaporation, but no artificial tannin can be obtained, as from the action of nitric acid on other resins.

Formerly guaiacum was much commended in siphilis and other complaints; at present it is used chiefly in rheumatism, dissolved in liquid ammonia.

GUANO. A substance found on many of the small islands on the South Sea, which are the resort of numerous flocks of birds, particularly of the ardea and phœnicopteros genus. It is dug from beds 50 or 60 feet thick, and used as a valuable manure in Peru, chiefly for Indian corn. It is of a dirty yellowish colour, nearly insipid to the taste, but has a powerful smell partaking of castor and valerian. According to the analysis of Fourcroy and Vauquelin, about one-fourth of it is uric acid, partly saturated with ammonia and lime. It contains likewise oxalic acid, partly saturated with ammonia and potash; phosphoric acid combined with the same bases and with lime; small quantities of sulphate and muriate of potash, and ammonia; a small portion of fat matter; and sand, partly quartzose, partly ferruginous.

GUARD, in a general sense, signifies the defence or preservation of any thing; the act of observing what passes, in order to prevent surprise; or the care, precaution, and attention we make use of, to prevent any thing happening contrary to our intention.

Guard, in the military art, is a duty performed by a body of men, to secure an army or place from being surprised by an enemy.

Guard, *advanced*, is a party of either horse or foot, that marches before a more considerable body, to give notice of approaching danger.

Guard-*boat*, a boat appointed to row the rounds among the ships of war in any harbour, to observe that their officers keep a good look-out, calling to the guard-boat as she passes, and not suffering her crew to come on board, without having previously communicated the watch-word of the night.

Guard-*ship*, a vessel to superintend the marine affairs in a harbour or river, and to see that the ships which are not commissioned have their proper watch duly kept; she is also to receive seamen who are impressed in time of war; she generally has an admiral's flag at one of her mast's head.

Guard, in fencing, is a posture proper to defend the body from an enemy's sword.

There are four general guards of the sword; to form a perfect idea of which, we must suppose a circle drawn on a wall, and divided into four cardinal points, *viz.* top and bottom, right and left. When the point of the sword is directed to the bottom of the circle, with the hilt opposite to its top, the body inclining very forward, this is called the prime or first guard. The second guard is, when the point is directed to the right or second point of the same circle, with the hilt of the sword turned to the left, and the body proportionably raised. The tierce, or third guard, is when the point of the sword is raised to the uppermost part of the same circle; in which case the body, the arm, and the sword, are in their natural position, and in the mean of the extremes of their motion. The quart, or fourth guard, is when the point of the sword is directed to the fourth point of the circle, descending to the right as far as one fourth of the tierce, with the outward part of the arm and the flat of the sword turned towards the ground, and the body out of the line to the right, and the hilt of the sword towards the line to the left. There is also a quint, or fifth guard, which is only the return of the point of the sword to the right, after traversing the circle to the point of the prime, from whence it had departed, with a different disposition of the body, arm, and sword. The common centre of all those motions ought to be in the shoulder.

GUARDIAN, one appointed by the wisdom and policy of the law, to take care of a person and his affairs, who by reason of his imbecility and want of understanding, is incapable of acting for his own interest.

There are several kinds of guardians, as, guardian by nature, guardian by the common law, guardian by statute, guardian by custom, guardian in chivalry, guardian in soccage, and guardian by appointment of the Lord Chancellor.

Guardian, *by nature*, is the father or mother: and by the common law every father has a right of guardianship of the body of his son and heir, until he attains the age of twenty-one years.

This guardianship extends no farther than the custody of the infant's person.

The father may disappoint the mother, and other ancestors, of the guardianship by nature, by appointing a testimentary guardian

Guardian, *by the common law.* If a tenant in soccage dies, his heir being under fourteen, whether he is his issue or cousin, male or female, the next of blood to the heir, to whom the inheritance cannot descend, shall be guardian of his body and land till the age of fourteen: the heir after fourteen may choose his own guardian, who shall continue till he is twenty-one.

Guardian, *by the statute.* The principal guardianship is now by the statute 12 Charles II. c. 24, by which any father, under or of full age, may by deed or will, attested by two witnesses, appoint, dispose of the custody of his child born or unborn to any person except a popish recusant convict, either in possession or reversion till such child attain twenty-one. This guardian supersedes the guardian in soccage, and has all actions which that guardian might have had. Besides which he has the care of the estate, real and personal. A father cannot under this statute appoint one to his natural child, and a case has been decided upon the marriage act, in which a marriage with consent of a guardian applied to a natural child was held void. The chancellor, however, will upon application appoint the same person guardian.

Guardian, *by appointment of the Lord Chancellor.* The Court of Chancery is the only proper court that hath jurisdiction in appointing and removing guardians, and in preventing them and others from abusing their persons or

estates. And as the Court of Chancery is now vested with this authority, we find that court determining, as to the right of guardianship, who is the next of kin, and who the most proper guardian; also orders are made by that court on petition or motion, for the provision of infants during any dispute therein; likewise guardians removed or compelled to give security: they and others punished for abuses committed on infants, and effectual care taken to prevent any abuses intended them in their persons or estates. All courts of justice appoint guardians to infants, to see and prosecute their rights in their respective courts, when the occasion calls for it.

There are also some cases where an infant may elect a guardian, and the Court of Chancery allows him to do so after fourteen.

GUARDIAN *of the Spiritualities*, is he to whom the spiritual jurisdiction of any diocese is committed, during the vacancy of the see. The archbishop is guardian of the spiritualities, on the vacancy of any see within his province.

GUILD (from the Saxon guildan " to pay,") signifies a fraternity or company, because every one was gildare, that is, to pay something towards the charge and support of the company. As to the original of these guilds or companies, it was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed: upon which certain neighbours, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party; that they might the better do this, they raised a sum of money among themselves, which they put into a common stock. These guilds are now companies joined together, with laws and orders made by themselves, by the licence of the prince.

GUITAR, or GUITARRA, a musical instrument of the string-kind, with five double rows of strings, of which those that are bass, are in the middle, unless it be for an octave lower than the fourth.

GULA, or GOLA. See ARCHITECTURE.

GULES, in heraldy, signifies the colour red, which is expressed in engraving by perpendicular lines falling from the top of the escutcheon to the bottom.

GUM. The mucilage of vegetables. The principal gums are, 1. The common gums obtained from the plum, the peach, the cherry tree, &c. 2. Gum Arabic, which flows naturally from the acacia in Egypt, Arabia, and elsewhere. This forms a clear transparent mucilage with water. 3. Gum Seneca, or Senegal. It does not greatly differ from gum Arabic; the pieces are larger and clearer; and it seems to communicate a higher degree of the adhesive quality to water. It is much used by calico-printers and others. The first sort of gums are frequently sold by this name, but may be known by their darker colour. 4. Gum Adragant or Tragacanth. It is obtained from a small plant of the same name growing in Syria, and other eastern parts. It comes to us in small white contorted pieces resembling worms. It is usually dearer than other gums, and forms a thicker jelly with water.

Mr. Willis has found that the root of the common blue-bell *hyacinthus non scriptus*, dried and powdered, affords a mucilage possessing all the qualities of that from gum Arabic. Lord Dundonald has extracted a mucilage also from lichens.

Gums treated with nitric acid afford the acid of sugar. See APPENDIX.

GUM *Elastic*. See CAOUTCHOUC.

GUM *Resin*. The principal gum resins are frankincense, scammony, asafœtida, aloes, gum ammoniac, and gamboge.

GUN, a fire arm or weapon of offence, which forcibly discharges a ball, shot, or other offensive matter, through a cylindrical barrel, by means of gunpowder. Gun is a general name, under which are included divers, or even most species of fire arms. They may be divided into great and small.

Great guns, called also by the general name cannons, make what we also call ordnance or artillery; under which come the several sorts of cannon.

GUNDELIA, a genus of the class and order syngenesia polygamia segregata. There is one species, an herb of the Levant, having the habit of a thistle.

GUNNERA, a genus of the class and order gynandria diandria. There is one species, a herb of the Cape.

GUNNERY, is the art of determining the course and directing the motion of bodies shot from artillery, or other warlike engines.

The great importance of this art is the reason it is distinguished from the doctrine of projectiles in general; for it is no more than an application of those laws which all bodies observe when cast into the air, to such as are put in motion by the explosion of guns or other engines of that sort.

Although numerous experiments had been tried on the subject of gunnery, no general principle seems to have been established from them, till Mr. Benjamin Robins, in 1742, published his *New Principles of Gunnery, containing the determination of the force of Gunpowder, and the investigation of the differences in the resting power of the air to swift and slow motions*. The following are the principal of the practical maxims of that eminent artificer, relative to the effects and management of artillery, the flight of shot and shells.

Maxim 1. In any piece of artillery whatever, the greater quantity of powder it is charged with, the greater will be the velocity of the bullet.

2. If two pieces of the same bore, but of different lengths, are fired with the same charge of powder, the longer will impel the bullet with a greater celerity than the shorter.

3. If two pieces of artillery different in weight, and formed of different metals, have their cylinders of equal bores and equal lengths; then, with like charges of powder, and like bullets, they will each of them discharge their shot with nearly the same celerity.

4. The ranges of pieces at a given elevation, are no just measure of the velocity of the shot, for the same pieces fired successively at an invariable elevation with the powder, bullet, and every other circumstance as nearly the same as possible, will range to different distances.

5. The greatest part of that uncertainty in the range of pieces, arises from the resistance of the air.

6. The resistance of the air acts upon the

projectiles in a two-fold manner. for it opposes their motion, and by that means continually diminishes their celerity; and it, besides, perpetually diverts them from the regular course they would otherwise follow.

7. If the same piece of cannon be successively fired at an invariable elevation, but with various charges of powder, the greatest charge being the whole weight of the bullet in powder, and the least not less than the fifth of that weight; then if the elevation be not less than 8° or 10°, it will be found that some of the ranges with the least charge will exceed some of those with the greatest.

8. If two pieces of cannon of the same bore, but of different lengths, are successively fired at the same elevation. with the same charge of powder, then it will frequently happen that some of the ranges with the shorter piece will exceed some of those with the longer.

9. In distant cannonadings, the advantages arising from long pieces and large charges of powder, are but of little moment.

10. Whatever operations are to be performed by artillery, the least charges of powder with which they can be effected are always to be preferred.

11. No field-piece ought at any time to be loaded with more than one sixth, or at the utmost one fifth of the weight of its bullet in powder. Nor should the charge of any battering piece exceed one third of the weight of its bullet.

12. The depth to which a bullet penetrates in a solid substance is a much more definite criterion of its comparative velocity than the distance to which it ranges when fired at an elevation; for with different velocities, the penetrations vary in a much greater proportion than the velocities themselves.

For the demonstration of this, Mr. Robins invented a machine which simply consists of a pendulous block of wood suspended freely by a horizontal axis, against which block the balls are fired.

GUNPOWDER. This well known powder is composed of 75 parts, by weight, of nitre, 16 of charcoal, and 9 of sulphur, intimately blended together by long pounding in wooden mortars, with a small quantity of water. This proportion of the materials is the most effectual. But the variations of strength in different samples of gunpowder are generally occasioned by the more or less intimate division and mixture of the parts. The reason of this may be easily deduced from the consideration, that nitre does not detonate until in contact with inflammable matter; whence the whole detonation will be more speedy, the more numerous the surfaces of contact. The same cause requires that the ingredients be very pure, because the mixture of foreign matter not only diminishes the quantity of effective ingredients which it represents, but likewise prevents the contacts by its interposition.

The nitre of the third boiling is usually chosen for making gunpowder, and the charcoal of light woods is preferred to that of those which are heavier, most probably because this last, being harder, is less pulverable.

The requisite pounding of the materials is performed in the large way, by a mill, in which wooden mortars are disposed in rows, and in each of which a pestle is moved by the arbor of a water-wheel: it is necessary to moisten the mixture from time to time with water, which serves to prevent its being dissipated in the pulverulent form, and likewise obviates the danger of explosion from the heat occasioned by the blows. Twelve hours' pounding is in general required to complete the mixture; and when this is done, the gunpowder is in fact made, and only requires to be dried to render it fit for use.

The granulation of gunpowder is performed by placing the mass, while in the form of a stiff paste, in a wire sieve, covering it with a board, and agitating the whole: by this means it is cut into small grains or parts, which, when of a requisite dryness, may be rendered smooth or glossy by rolling them in a cylindrical vessel or cask. Gunpowder in this form takes fire more speedily than if it be afterward reduced to powder, as may be easily accounted for from the circumstance, that the inflammation is more speedily propagated through the interstices of the grains. But the process of granulation does itself, in all probability, weaken the gunpowder, in the same manner as it is weakened by suffering it to become damp; for, in this last case, the nitre, which is the only soluble ingredient, suffers a partial solution in the water, and a separation in crystals of greater or less magnitude; and accordingly the surfaces of contact are rendered less numerous.

GUNTER'S *chain*, the chain in common use for measuring land, according to the true or statute measure; so called from Mr. Gunter its inventor.

The length of the chain is 66 feet, or 22 yards, or four poles of five yards and a half each; and it is divided into 100 links, of 7.92 inches each.

This chain is the most convenient of any thing for measuring land, because the contents thence computed are so easily turned into acres. The reason of which is, that an acre of land is just equal to 10 square chains, or 10 chains in length and one in breadth, or equal to 100,000 square links. Hence the dimensions being taken in chains, and multiplied together, it gives the content in square chains; which therefore being divided by 10, or a figure cut off for decimals, brings the content to acres; after which the decimals are reduced to roods and perches, by multiplying by 4 and 40.

GUNTER'S *line*, a logarithmic line, usually graduated upon scales, sectors, &c. It is also called the line of lines, and line of numbers. It is usually divided into a hundred parts, every tenth of which is numbered, beginning with 1, and ending with 10; so that if the first great division, marked 1, stand for one-tenth of any integer, the next division, marked 2, will stand for two-tenths; 3, three-tenths, and so on; and the intermediate divisions will, in like manner, represent 100th parts of some integer. If each of the great divisions represent 10 integers, then will the lesser divisions stand for integers; and if the great divisions be supposed each 100, the subdivisions will be each 10.

USE OF GUNTER'S LINE.

1. *To find the product of two numbers.* From 1 extend the compasses to the multiplier and the same extent, applied the same way from the multiplicand, will reach to the product. Thus, if the product of 4 and 8 be re-

quired, extend the compasses from 1 to 4 and that extent laid from 8 the same way, will reach to 32, their product.

2. *To divide one number by another.* The extent from the divisor to unity will reach from the dividend to the quotient: thus to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought.

3. *To three given numbers, to find a fourth proportional.* Suppose the numbers 6, 8, 9; extend the compasses from 6 to 8, and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required.

4. *To find a mean proportional between any two given numbers.* Suppose 8 and 32: extend the compasses from 8 in the left-hand part of the line, to 32 in the right; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16 the mean proportional sought.

5. *To extract the square root of any number.* Suppose 25: bisect the distance between 1 on the scale and the point representing 25; then the half of this distance, set off from 1, will give the point representing the root 5. In the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line, between 1 and the given number, into as many equal parts as the index of the power expresses; then one of those parts, set from 1, will find the point representing the root required.

Gunter's *quadrant*, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere, on the plane of the equinoctial; the eye being supposed placed in one of the poles.

Besides the use of this quadrant in finding heights and distances, it serves also to find the hour of the day, the sun's azimuth, and other problems of the globe.

Gunter's *scale*, usually called by seamen *the Gunter*, is a large plane scale having various lines upon it, of great use in working the cases or questions in navigation.

This scale is usually two feet long, and about an inch and a half broad, with various lines upon it, both natural and logarithmic, relating to trigonometry, navigation, &c.

On one side are the natural lines, and on the other the artificial or logarithmic ones. The former side is first divided into inches and tenths, and numbered from 1 to 24 inches, running the whole length near one edge. One-half the length of this side consists of two plane diagonal scales, for taking off dimensions to three places of figures. On the other half or foot of this side are contained various lines relating to trigonometry, in the natural numbers, and marked thus, viz.

Rumb. the rumb or points of the compass;
Chord. the line of chords;
Sine, the line of sines;
Tang. the tangents;
S. T. the semitangents; and at the other end of this half are,
Leag. leagues, or equal parts,
Rumb. another line of rumbs;
M. L. miles of longitude:
Chor. another line of chords.

Also in the middle of this foot are *L.* and *P.* two other lines of equal parts. And all these lines, on this side of the scale, serve for drawing or laying down the figures to the cases in trigonometry and navigation.

On the other side of the scale are the following artificial or logarithmic lines, which serve for working or resolving those cases, viz.

S. R. the sine rumbs;
T. R. the tangent rumbs;
Numb. line of numbers;
Sine, sines;
V. S. the versed sines;
Tang. the tangents;
Meri. meridional parts;
E. P. equal parts.

GUN-*wale*, or *gunnel*, is the uppermost wale of a ship, or that piece of timber which reaches on either side from the quarter-deck to the forecastle.

GUST, in sea-language, a sudden and violent squall of wind, bursting from the hills upon the sea, so as to endanger the shipping near the shore.

GUTTA-*serena*, a disease in which the patient, without any apparent fault in the eye, is entirely deprived of sight.

GUTTY, in heraldry, a term used when any thing is charged or sprinkled with drops.

GUY, in a ship, is any rope used for keeping off things from bearing or falling against the ship's sides when they are hoisting in.

GYMNASTICS. This word, derived from the Greek, comprehends all those athletic exercises by which the ancients rendered the body pliant and healthy, and enabled the muscles to do their offices with treble effect. Several very respectable works on the subject of gymnastic exercises have recently appeared, which, it is hoped, will tend much to excite a spirit for that manly and healthful exercise of the physical powers, for which the Greeks and Romans were so celebrated, and banish for ever from the Island, the brutal taste for prize-fighting, which has so long disgraced the English name.

GYMNOTUS, the *gymnote*, in natural history, a genus of fishes of the order Apodes. This fish, which is found in the hot climates of Africa and America, and in the rivers of Surinam and Senegal, is noted for its possessing the remarkable quality of communicating to the person who touches it a very sudden and violent shock, resembling that experienced from the voltaic apparatus.

The following interesting account of this fish we copy from the Edinburgh Philosophical Journal, No. 21.

Structure of Electric Organs of Gymnotus Electricus.

On each side there is an upper large, and an under small electric organ. The large organ arises immediately behind the head, under the great dorsal muscles, where it is obtuse and gradually becomes narrower, and terminates acutely towards the end of the tail. It is straight, or somewhat hollowed towards the back-bone, but convex in the opposite direction: above, it terminates in a line; in a nearly similar manner below, and is thickest in the middle.

It is composed of horizontal plates, about the third of a line from each other, which are traversed at right angles by partition walls, and in the small space between them water is contained. Below this large organ lies a similar,

but smaller and more minutely divided one. These parts are supplied with numerous intercostal nerves: in the specimen examined by Rudolphi, 224, were observed on each side. A great branch of the third branch of the fifth pair of nerves, augmented by a smaller branch from the vagus, runs parallel with the backbone, from the head to the tail, where it divides. This nerve runs immediately over the intercostal nerves, and crosses them at right angles, without, however, uniting with them in any way; on the contrary, they are entirely distributed to the muscles of the back. This is the nerve which Hunter describes as the vagus, and which Fahlberg erroneously considered as the electric nerves; while Hunter, with his usual accuracy, describes the intercostal nerves as those of the electric organs. If we compare the electric organs of the torpedo and gymnosus electricus, the first may be compared with the voltaic pile, the second with the trough apparatus. But they agree in their principal feature, viz. in the abundant distribution of nerves to very vascular plates between which a serous fluid is disposed.

GYMNETRUS, a genus of fishes, of the order of thoracici. The generic character is, body extremely long, compressed; teeth numerous, subulate; gill membrane, four or five-rayed; anal fin wanting. The most remarkable species is gymnetrus Ascanii, or Ascanian gymnetrus.

This fish is said to be generally seen either preceding or accompanying the shoals of herrings in the northern seas, for which reason it is popularly known by the title of king of the herrings.

GYNANDRIA, *from γυνη, a woman,* and *ανηρ, a man,* the name of the 20th class in Linnaeus's sexual system, consisting of plants with hermaphrodite flowers, in which the stamina are placed upon the style, or, to speak more properly, upon a pillar-shaped receptacle resembling a style, which rises in the middle of the flower, and bears both the stamina and pointal; that is, both the supposed organs of generation. The flowers of this class, says Linnaeus, have a monstrous appearance; arising as he imagines, from the singular and unusual situation of the parts of fructification.

GYPSIES, are wandering tribes who live, in general, in the most extreme state of wretchedness, and seem to hold in contempt every thing that has a tendency to raise human beings above the state of absolute barbarism. They are very numerous on the Continent; in England much less so; and in Scotland they are now extremely few. Their origin, although generally supposed to be Egyptian, is involved in great obscurity. In this country, as well as on the Continent, their general *profession* is that of working in iron and brass, which is only a sort of cover for the manner in which they obtain their living. It is, however, but justice to state, that at present many of them, particularly in the midland counties of England, are regularly licensed hawkers, who although they still keep themselves distinct in society, exhibit many proofs of industry, and in the winter season reside in towns, and send their children to school; from which circumstances it may rationally be expected that they will gradually become incorporated with civilized society.

GYPSUM, a substance well known to the ancients, and one that is very abundant in nature, and is now denominated, according to the new chemical arrangement, the sulphate of lime. It forms immense strata, composing entire mountains; it is found in almost every soil; it is contained in the waters of the ocean, and in almost all river and spring water. In these its presence is the cause of the quality termed hardness, which may be known by the water being incapable of forming a solution of soap, the sulphuric acid seizing on the alkali of the soap, and the oil forming a compound with the lime. Sulphate of lime is insipid, white, and soft to the touch. Water will not hold a 500th part of it in solution. Exposed to heat it appears to effervesce, which phenomenon is caused by the expulsion of water. It becomes opaque, and falls into powder. This powder, when its water has been driven off by the application of a red heat, absorbs water rapidly, so that if it be formed into a paste with water, it dries in a few minutes. In this state it is called plaster of Paris, and is employed for forming casts, and for a variety of purposes in the art of statuary.

GYRINUS, the *water-flea,* a genus of insects of the order coleoptera. The natator, or common water flea, is of a bright black colour; the feet are yellow, flat, and large; the length of the insect is about one third of an inch. It runs with great celerity on the surface of the water, and is caught with great difficulty, plunging down instantaneously when attempted to be taken. There are eight other species, which frequent the waters in different parts of the world.

H.

H. This letter is the eighth in the English alphabet. By some it is denied the place of a consonant; but it evidently performs, in numerous instances, the office of one. It is used as a numeral, to denote 200; and with a dash over it, it denotes 200,000.

HABEAS *corpus,* a writ of various uses, and of different importance. It was originally a writ, which a man indicted of a trespass before justices of the peace, or in a court of franchise, and being apprehended for it, may have out of the King's Bench, to remove himself thither at his own costs, and to answer the cause there. In its more usual sense it is the most celebrated writ in the English law. The most efficacious kind, in all manner of illegal confinement, is that of *habeas corpus ad subjiciendum,* which is the subject's writ of right, in cases where he is aggrieved by illegal imprisonment, or any unwarrantable exercise of power.

This writ is founded upon common law, and has been secured by various statutes, of which the last and most efficacious, was 31 Charles II

c. 2, which is emphatically termed the habeas act, and may justly be deemed a second magna charta, and, as relates to modern times, is far more efficacious, for it is the grand protection of the subject against unlawful imprisonment.

HABIT, in philosophy, an aptitude or disposition either of mind or body, acquired by a frequent repetition of the same act.

HACKLE, an implement used in dressing flax.

HADDOCK. See GADUS.

HÆMANTHUS, the *blood flower*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the ninth order, spathaceæ. The involucrum is hexaphyllous and multiflorous; the corolla sexpartite, superior; the berry trilocular. There are eight species.

HÆMANTHUS, in botany, a genus of the hexandria monogynia class and order. Natural order of spathaceæ. Essential character; involucre six-leaved, many-flowered; coralla six-parted, superior; berry three-celled. There are eight species.

HÆMATOPUS, the *oyster-catcher*, in natural history, a genus of birds of the order Grallæ. Generic character: bill compressed, the tip an equal wedge: nostrils linear; tongue about third part of the length of the bill; toes three; all placed forwards, the outer one joined to the middle by a strong membrane. This bird is sixteen inches in length, and about the size of a crow; it is to be met with on almost every sea-shore, and is rather common in Great Britain, particularly on the Western coast.

HÆMATOXYLUM, *logwood*, or *Campeachy wood*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. Of this genus there is only one species, viz. the Campechianum, which grows naturally in the bay of Campeachy at Honduras, and other parts of the Spanish West Indies, where it rises from 16 to 24 feet high.

HÆMORRHAGE, in medicine, a flux of blood from any part of the body.

HÆRUCA, in entomology, a genus of the order of vermes intestina. The body is round, the forepart two-necked, and surrounded with a single row of prickles. The H. muris is grey-white and wrinkled; it inhabits the intestines of the mouse, and is distinguished from the echinorhynchus, in wanting the retractile proboscis.

HAIL, a meteor generally defined frozen rain, but differing from it in that the hailstones are not formed of single pieces of ice, but of many little spherules agglutinated together. Neither are these spherules all of the same consistence; some of them being hard and solid like perfect ice; others soft, and mostly like snow hardened by a severe frost. Sometimes the hailstone has a kind of core of this soft matter; but more frequently the core is solid and hard, while the outside is formed of a softer matter. Hailstones assume various figures, being sometimes round, at other times pyramidal, crenated, angular, thin, and flat, and sometimes stellated, with six radii like the small crystals of snow.

HAILING, in naval language, the salutation or accosting a ship at a distance, which is usuallpe yrformed with a speaking-trumpet; the first exclamation is "hoa, the ship, a hoay," to which she replies "holloa;" then follow the requisite questions and replies.

HAIR, small filaments issuing out of the pores of the skins of animals, and serving most of them as a tegument or covering. In lieu of hair, the nakedness of some animals is covered with feathers, wool, scales, &c. Hair is found on all parts of the human body, except the soles of the feet and the palms of the hands; but it grows longest on the head, chin, breast, in the armpits, &c. It is known that every hair does properly and truly live, and receive nutriment to fill and distend it like the other parts; which they argue hence, that the roots do not turn grey in aged persons sooner than in young persons.

It may be observed, however, that, in propriety, the life and growth of hairs is of a different kind from that of the rest of the body, and is not immediately derived therefrom, or reciprocated therewith. It is rather of the nature of vegetation. They grow as plants do out of the earth; or, as some plants shoot from the parts of others, from which though they draw their nourishment, yet each has, as it were, its several life, and a distinct economy. They derive their food from some juices in the body, but not from the nutritious juices; whence they may live though the body be starved.

The hairs ordinarily appear round or cylindrical; but the microscope also discovers triangular and square ones, which diversity of figure arises from that of the pores, to which the hairs always accommodate themselves. Their length depends on the quantity of the proper humour to feed them, and their colour on the quality of that humour, whence, at different stages of life, the colour usually differs. Their extremities split into two or three branches, especially when kept dry, or suffered to grow too long, so that what appears only a single hair to the naked eye, seems a brush to the microscope. From numerous experiments M. Vauquelin infers, that black hair is formed of nine different substances, namely:

1. An animal matter, which constitutes the greater part. 2. A white concrete oil in small quantity. 3. Another oil of a greyish green colour, more abundant than the former. 4. Iron, the state of which in the hair is uncertain. 5. A few particles of oxide of manganese. 6. Phosphate of lime. 7. Carbonate of lime, in very small quantity. 8. Silex, in a conspicuous quantity. 9. Lastly, a considerable quantity of sulphur.

The same experiments shew, that red hair differs from black only in containing a red oil, instead of a blackish-green oil: and that white hair differs from both these only in the oil being nearly colourless, and in containing phosphate of magnesia, which is not found in them.

HAIR, or DOWN, *of plants*, a general term, expressive of all the hairy and glandular appearances on the surface of plants, to which they are supposed by naturalists to serve the double purpose of defensive weapons and vessels of secretion. These hairs are minute threads, of greater or less length and solidity, some of them visible to the naked eye, whilst others are rendered visible only by the help of glasses.

HAIR'S *breadth*, a measure of length, being the forty-eighth part of an inch.

HAKE, in ichthyology, the English name of the gadus, with two fins on the back, and the under-jaw longest. It grows to two feet or more in length, but is the slenderest of all the gadi. See GADUS.

HALBARD, or *halbert*, in the art of war, a well-known weapon, carried by the serjeants of foot and dragoons. It is a sort of spear, the shaft of which is about five feet long, and made of ash or other wood. Its head is armed with a steel point, edged on both sides, not unlike the point of a two-edged sword: but besides this sharp point, which is in a line with the shaft, there is a cross piece of steel, flat and pointed at both ends; but generally with a cutting edge at one extremity, and a bent sharp point at the other; so that it serves equally to cut down, or thrust.

HALF-*moon*, in fortification, an out-work composed of two faces, forming a saliant angle, whose gorge is in form of a crescent, or half-moon.

HALIOTIS, the ear-shell, a genus of insects belonging to the order of vermes testacea. This is an animal of the snail kind, with an open shell resembling an ear. There are nineteen species, distinguished by the figure of their shells.

HALLERIA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. There is one species, a shrub of the Cape.

HALLIARDS, in sea language, the ropes or tackles usually employed to hoist or lower any sail upon its respective masts or stay.

HALO, in physiology, a meteor in the form of a luminous ring or circle, of various colours, appearing round the bodies of the sun, moon, or stars. See METEOROLOGY.

HAMMER, a well-known tool used by mechanics, consisting of an iron head, fixed crosswise upon a handle of wood.

HAMMOCK, in naval affairs, a piece of hempen cloth six feet long and three feet wide, gathered together at the two ends by means of a clue, and slung horizontally under the deck, forming a receptacle for a bed.

HANAPER *office*, in the court of chancery, is that out of which issue all original writs that pass under the great seal, and all commissions of charitable uses, sewers, bankrupts, idiocy, lunacy, and such like. These writs, relating to the business of the subject, and the returns to them, were originally kept in a hamper, in hanaperio; the other writs, relating to matters wherein the crown is immediately or mediately concerned, were preserved in a little sack or bag, in parva baga; and thence has arisen the distinction of the hanaper office and petty-bag office: both of which belong to the common-law court in chancery.

HAND. See ANATOMY.

HAND *breadth*, a measure of three inches. By this standard the height of horses is estimated.

HAND *cuffs*, an instrument formed of two circular pieces of iron, each fixed on a hinge on the ends of a very short iron bar, which being locked over the wrists of a malefactor prevents his using his hands.

HAND *spikes*, wooden levers used at sea to traverse the ordnance, or to turn the windlass in weighing up the anchor, &c.

HANDS, in heraldry, are borne in coat-armour dexter and sinister, that is, right and left, expanded or open.

HANSE *towns*, port-towns of Germany, of which Lubec and Hamburgh were the chie. They were formerly all of them imperial cities, confederated for their mutual defence, and the protection of their trade.

HARBOUR, a place where ships may ride safe at anchor, chiefly used in speaking of those secured by a boom and chain, and furnished with a mole.

HARDNESS, in physiology, is the resistance opposed by a body to the separation of its particles. This property depends on the force of cohesion, or on that which chemists call affinity, joined to the arrangement of the particles to their figure and other circumstances. A body, says M. Hauy, is considered more hard in proportion as it presents greater resistance to the friction of another hard body, such as a steel file; or as it is more capable of wearing or working into such other body to which it may be applied by friction. Lapidaries judge of the hardness of fine stones, &c. from the difficulty with which they are worn down or polished.

HARE. See LEPUS.

HARIOT, or *heriot*, in law, a due belonging to a lord at the death of his tenant, consisting of the best beast, either horse, ox, or cow, which he had at the time of his death; and in some manors, the best goods, piece of plate, &c. are called hariots. There is both hariot-service, and hariot-custom: when a tenant holds by service to pay a hariot at his decease, which is expressly reserved in the deed of feoffment, this is a hariot service; and where hariots have been customarily paid time out of mind after the death of a tenant for life, this is termed hariot custom.

HARMATTAN, the name given to a singular wind which blows periodically from the interior parts of Africa towards the Atlantic ocean. It prevails in December, January, and February, and is generally accompanied with a fog or haze that conceals the sun for whole days together. Extreme dryness is the characteristic of this wind: no dew falls during its continuance, which is sometimes for a fortnight or more. The whole vegetable creation is withered, and the grass becomes at once like hay. The natives take the opportunity which this wind gives them of clearing the land by setting fire to trees and plants in this their exhausted state. The dryness is so extreme that household furniture is damaged, and the wainscot of the rooms flies to pieces. The human body is also affected by it, so as to cause the skin to peel off, but in other respects it is deemed salutary to the constitution, by stopping the progress of infection, and curing almost all cutaneous diseases.

HARMONICA, or ARMONICA, is a name which Dr. Franklin has given to a musical instrument constructed with drinking-glasses.

This fine instrument was originally composed of a number of glasses of different sizes, fixed on a spindle; the whole was placed in a kind of frame, and made to revolve by a wheel and band after the manner of the spindle of a turning lathe, and the sounds were produced by applying the points of the fingers dipped in water, to the edge of the glasses while revolv-

ing. But this form of the instrument is now become obsolete; the glasses are arranged on a board, in which their base is made fast; they are tuned by partially filling them with water, and the performer by dexterously touching their edges with his wetted fingers, communicates to them a vibratory motion, thus drawing from them a fulness and richness of tone unequalled by any other musical instrument whatever.

HARMONICAL *Arithmetic*, that part of arithmetic which considers musical intervals expressed by numbers, in order to our finding their mutual relations, compositions, and resolutions.

HARMONICAL *Proportion*. See PROPORTION.

HARMONICAL *Series*, a series of many numbers in continual harmonical proportion.

HARMONICAL *sounds*, an appellation given to such sounds as always make a determinate number of vibrations in the time that one of the fundamentals, to which they are referred, makes one vibration.

HARMONICS, that part of music which considered the differences and proportions of sounds, with respect to acute and grave; in contradistinction to rhyme and metre.

HARMONY, in music, the agreeable result or union, of several musical sounds, heard at one and the same time; or the mixture of divers sounds, which together have an effect agreeable to the ear. As a continued succession of musical sounds produces melody, so does a continued combination of these produce harmony.

HARMONY *of the spheres*, or *Celestial Harmony*, a sort of music much talked of by many of the ancient philosophers and fathers, supposed to be produced by the sweetly-tuned motions of the stars and planets. This harmony they attributed to the various proportionate impressions of the heavenly globes upon one another, acting at proper intervals.

HARP, a musical instrument of the string kind, of a triangular figure, held upright between the legs of the person who plays upon it.

HARP, *Eolian*. See ACOUSTICS.

HARPINGS, in a ship, properly denote her breadth at the bow. Some also give the same name to the ends of the bends that are fastened into the stern.

HARPSICHORD, a stringed instrument consisting of a case formed of mahogany or walnut-tree wood, and containing the belly or sounding-board, over which the wires are distended, supported by bridges. But since the invention of that fine instrument, the grand piano-forte, its practice has considerably declined.

HARPOON, an iron spear used to strike the whales in the Greenland and South Sea fisheries. It is furnished with a long shank, and has, at the one end, a broad and flat triangular head, sharpened at both edges: to the other end of this weapon is fastened a long cord which lies carefully coiled in the boat, so as to run out without being entangled.

The gun-harpoon is a weapon used for the same purpose, but is fired out of a gun, instead of being thrown by hand. It is made of steel, and has a chain attached to it, to which the line is fastened.

HARRIER. See CANIS.

HART. See CERVUS.

HAT *Manufactory*. The art of making common hats not involving the description of any complex machinery, or of any very interesting process, we shall content ourselves with the following very general idea of the method generally pursued.

The materials for making hats are rabbits' fur, cut off from the skin, after the hairs have been plucked out, together with wool and beaver. The two former are mixed in various proportions, and of different qualities, according to the value of the article intended to be made; and the latter is used for facing the finer articles. These articles cannot be evenly felted together unless all the fibres be first separated, or put into the same state with regard to each other. This is the object of the process called bowing. The materials are laid upon an open platform of wood or wire, somewhat more than four feet square, called a hurdle, which is fixed against the wall. The workman is provided with a bow or pole of yellow deal-wood, between seven and eight feet long, with two bridges, over which are stretched a catgut, about one-twelfth part of an inch in thickness. The materials being shovelled with a basket towards the right hand end of the hurdle, the workman holding the bow horizontally in his left-hand, lightly places the bow-string, and gives it a pluck with a knobbed stick called the bow-pin. The string in its return, strikes part of the fur, and causes it to rise, and fly partly across the hurdle in a light open form. The quantity bowed at once is called a batt, and never exceeds half that required to make one hat. When the hat is sufficiently bowed, it is ready for hardening. The prepared material being evenly disposed on the hurdle, is covered with a cloth, and pressed successively in its various parts by the hands of the workman. The pressure is gentle, and the hands are very slightly moved backwards and forwards, to favour the entangling of the fibres. In a very short time the stuff acquires sufficient firmness to bear careful handling. The cloth is then taken off, and a sheet of paper, with its corners doubled in, so as to give it a triangular outline, is laid upon the batt, which last is folded over the paper as it lies, and its edges, meeting one over the other, form a conical cap. The joining is soon made good by pressure with the hands on the cloth. Another batt, ready hardened, is then laid on the hurdle, and the cap placed upon it, with the joining downwards. The principal part of the hat is thus put together, and now requires to be worked with the hands a considerable time upon the hurdle, the cloth being occasionally sprinkled with clear water. This is followed by a still more effectual continuation of the felting, called working. This is done in an apparatus called a battery, consisting of a kettle containing water acidulated with sulphuric acid, and eight planks of wood joined together in the form of a frustum of a pyramid, and meeting in the kettle at the middle. The liquor being heated rather higher than unpractised hands could bear, the article is dipped from time to time, and worked on the planks with a roller, and also by folding or rolling it up, and opening it again. The beaver is laid on towards the conclusion of this kind of working. Beer grounds

are used with beaver hats, to render the liquor more tenacious, so that the hat is enabled to hold a greater quantity of it for a longer time.

The next thing to be done is to give it the form required by the wearer. For this purpose, the workman turns up the edge or rim to the depth of about an inch and a half, and then returns the point back again through the centre or axis of the cap, so far as not to take out this fold, but to produce another inner fold of the same depth. The point being returned back again in the same manner produces a third fold; and thus the workman proceeds until the whole has acquired the appearance of a flat circular piece. This is laid upon the plank, where the workman, keeping the piece wet with the liquor, pulls out the point with his fingers, and presses it down with his hand, at the same time, turning it round on its centre in contact with the plank, till he has, by this means rubbed out a flat portion equal to the intended crown of the hat. In the next place he takes a block, to the crown of which he applies the flat central portion of the felt, and by forcing a string down the sides of the block, he causes the next part to assume the figure of the crown, which he continues to wet and work until it has properly disposed itself round the block. The rim now appears like a flounced or puckered appendage round the edge of the crown; but the block being set upright on the plank, the requisite figure is soon given by working, rubbing, and extending this part.

Previous to the dying, the nap of the hat is raised or loosened out with a wire-brush. The dying materials are logwood and a mixture of the sulphates of iron and copper, known in the market by the names of green copperas and blue vitriol.

The dyed hats are taken to the stiffening shop. One workman, assisted by a boy, does this part of the business. He has two vessels or boilers, the one containing the grounds of strong beer, which are applied to the inside of the crown to prevent the glue from coming through to the face. The glue stiffening is applied after the beer-grounds are dried, and then only upon the lower face of the flap, and the inside of the crown. For this purpose the hat is put into another hat, called a stiffening hat, the crown of which is notched, or slit open, in various directions. These are then placed in a hole in a deal board, which supports the flap, and the glue is applied with a brush. The dry hat, after this operation, is very rigid, and its figure irregular. The last dressing is given by the application of moisture and heat, and the use of the brush and a hot iron, somewhat in the shape of that used by tailors, but shorter and broader on the face.

When the rim of the hat is not intended to be of an equal width throughout, it is cut by means of a wooden or metallic pattern. When the hat is completely finished, the crown is tied up in gauze paper, which is neatly ironed down. It is then ready for the subsequent operations of lining, &c.

Hats are also made of chips, straw, or cane, by platting, and sewing the plats together; beginning with the centre of the crown, and working round till the whole is finished. Hats are also wove and made of horse hair, silk, &c. See STRAW HAT.

HATCHEL, or HITCHEL, a tool with which flax and hemp are combed into fine hairs. It consists of long iron pins, or teeth, regularly set in a piece of board.

HATCHES, in a ship, a kind of trap-doors between the main-mast and fore-mast, through which all goods of bulk are let down into the hold.

HATCHES also denote flood-gates set in a river, &c. to stop the current of the water; particularly certain dams or mounds made of rubbish, clay, or earth, to prevent the water that issues from the stream-works and tin-washes in Cornwall, from running into the fresh rivers.

HATCHING, the maturating of fecundated eggs, whether by the incubation and warmth of the parent bird, or by artificial heat, so [illegible] produce young chickens alive.

The art of hatching chickens by me[illegible] of ovens, has long been practised in Egyp[illegible] it is there only known to the inhabitants of a single village named Berme, and to those that live at a small distance from it. Towards the beginning of autumn they scatter themselves all over the country, where each person among them is ready to undertake the management of an oven, each of which is of a different size; but in general they are capable of containing from forty to fourscore thousand eggs. The number of these ovens placed up and down the country is about three hundred and eighty-six, and they usually keep them working for about six months. As, therefore, each brood takes up in an oven, as under a hen, only twenty-one days, it is easy in every one of them to hatch eight different broods of chickens. Every Bermean is under the obligation of delivering to the person who intrusts him with an oven, only two-thirds of as many chickens as there have been eggs put under his care; and he is a gainer by this bargain, as more than two-thirds of the eggs usually produce chickens. In order to make a calculation of the number of chickens yearly so hatched in Egypt, it has been supposed that only two-thirds of the eggs are hatched, and that each brood consists of at least thirty thousand chickens; and thus it would appear that the ovens of Egypt give life yearly to at least ninety-two millions six hundred and forty thousand of these animals.

This operation has of late been effected in this country by the heat afforded by steam; but in artificial hatching, the chickens produced are always very much inferior to those produced in the natural way.

HAUTBOY, a musical instrument of the wind-kind, shaped much like the flute, only that it spreads and widens towards the bottom, and is sounded through a reed.

HAWK. See FALCO.

HAWKERS and *pedlars*, are such dealers or itinerary petty chapmen as travel to different fairs or towns with goods or wares, and are placed under the controul of commissioners, by whom they are licensed for that purpose pursuant to stat. 8 and 9, W. III. c. 25. and 29, Geo. III. c. 26. Traders in linen and woollen manufactories sending their goods to markets and fairs, and selling them by wholesale; manufacturers selling their own manufactures, and makers and sellers of English bone-lace going from house to house, &c. are excepted out of the acts, and not to be taken as hawkers.

HAWKING. See FALCONRY.

HAWSER, in the sea-language, a large

rope, or a kind of small cable, serving for various uses aboard a ship, as to fasten the main and fore shrouds, to warp a ship as she lies at anchor, and wind her up by a capstern, &c.

HAZARD, a game on dice, without tables, is very properly so called, since it speedily makes a man, or undoes him. It is played with only two dice; and as many may play it as can stand round the largest round table.

Two things are chiefly to be observed, viz. main and chance; the latter belonging to the caster, and the former, or main, to the other gamesters. There can be no main thrown above nine, nor under five; so that five, six, seven, eight, and nine, are the only mains flung at hazard. Chances and nicks are from fo[illegible] ten: thus four is a chance to nine, five to [illegible]t, six to seven, seven to six, eight to five; and nine and ten a chance to five, six, seven, and eight: in short, four, five, six, seven, eight, nine, and ten, are chances to any main, if any of these nick it not. Now nicks are either when the chance is the same with the main, as five and five, or the like; or six and twelve, seven and eleven, eight and twelve. Here observe, that twelve is out to nine, seven, and five; eleven is out to nine, eight, six, and five; and ames-ace and deuce-ace are out to all mains whatever.

HAZEL. See Carylus.

HEADBORROW, or Headborough, the chief of the frank pledge, and he that had the principal government of them within his own pledge. He was called also burrowhead, bursholder, third-burrow, tithing-man, chief-pledge, or borrow-elder. He is now occasionally called a constable.

HEAD-*lines*, in a ship, those ropes of all sails which are next to the yard, and by which they are made fast to the yard.

HEALTH, is a right disposition of the body, and of all its parts; consisting in a due temperature, a right confirmation, just connection, and ready and free exercise of the several vital functions.

HEARING. The organ of hearing is the ear, and particularly the auditory nerve and membrane. See Sound.

HEAT. See Caloric.

Heat, *animal.* See Respiration.

Heat, in geography, the diversity of the climates and seasons, arising chiefly from the different angles under which the sun's rays strike upon the surface of the earth. Dr. Halley gives a mathematical computation of the effect of the sun under the different seasons and climates. The different degrees of heat and cold in different places depend in a very great measure upon the accidents of situation, with regard to mountains and valleys, and the soil. The first greatly helps to chill the air by the winds which come over them, and which blow in eddies through the levels beyond; and mountains, sometimes turning a concave side to the sun, have the effects of a burning mirror upon the subject plain; and the like effect is sometimes had from the convex parts of clouds, either by refraction, or reflection. As to soils, a stony, sandy, or chalky earth, it is known, reflects most of the sun's rays into the air again, and retains but few, by which means a considerable accession of heat is derived to the air; as on the contrary, black loose soils absorb most of the rays, and return few into the air, so that the ground is much the hotter.

The following table of the heat of different climates is computed for every tenth degree of latitude, to the equinoctial and tropical sun; by which an estimate may be made of the intermediate degrees.

Lat.	Sun in ♈ ♎.	Sun in ♋	Sun in ♑
0	20000	18341	18341
10	19696	20290	15854
20	18797	21737	13166
30	17321	22651	10124
40	15321	23048	6944
50	12855	22991	3798
60	10000	22773	1075
70	6840	23543	000
80	3473	24673	000
90	0000	25055	000

HEATH. See Erica.

HEDERA, *ivy*, a genus of the monogynia order, in the pentandria class of plants; and in the natural method giving name to the 46th order, hederaceæ. There are five oblong petals, the berry is pentaspermous, girt by the calyx. There are six species with several varieties.

The roots of the ivy are used by leather-cutters to whet their knives upon. Apricots and peaches covered with ivy during the month of February, have been observed to bear fruit plentifully. The leaves have a nauseous taste; Haller says, they are given to children in Germany, as a specific for the atrophy. The common people of England apply them to issues; and an ointment made from them is in great esteem among the Highlanders of Scotland as a ready cure for burns. The berries have a little acidity. In warm climates, a resinous juice exudes from the stalks, which is said to be a powerful resolvent, and an excellent ingredient in plasters and ointments. Horses and sheep eat the plant; goats and cows refuse it.

HEDGES. See Agriculture.

HEDGE-*hog.* See Erinaceus.

HEDYSARUM, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The carina of the corolla is transversely obtuse; the seed-vessel a legumen with monospermous joints. There are ninety species, only one of which is a native of Great Britain; *viz.* H. onobrychis, saintfoin, or cocks-head, and but ten which are natives of Europe. Most of these are perennial. Linnæus relates a remarkable phenomenon belonging to H. gyrans, sensitive hedysarum, which is as follows: This is a wonderful plant, on account of its voluntary motion, which is not occasioned by any touch, irritation, or movement in the air, as in the Mimosa, Oxalis, and Dionæa; nor is it so evanescent as in Amorpha. No sooner had the plants raised from seed acquired their ternate leaves, than they began to be in motion this way and that: this movement did not cease during the whole course of their vegetation, nor were they observant of any time, order, or direction; one leaflet frequently revolved, whilst the other on the same petiole was quiescent; sometimes a few leaflets only

were in motion, then almost all of them would be in movement at once; the whole plant was very seldom agitated, and that only during the first year. It continued to move in the stove during the second year of its growth, and was not at rest even in winter.

Heel, in sea language. If a ship leans on one side, whether she be aground or afloat, she is said to heel a starboard, or a part; or that she heels offwards, or to the shore.

HEGIRA, in chronology, a celebrated epocha among the Mahometans. The event which gave rise to this epocha was the flight of Mahomet from Mecca, with his new proselytes, to avoid the prosecution of the Koraischites: who, being then most powerful in the city, could not bear that Mahomet should abolish idolatry, and establish his new religion. This flight happened in the fourteenth year after Mahomet had commenced prophet: he retired to Medina, which he made the place of his residence.

HEIGHT, in geometry, is a perpendicular let fall from the vertex, or top, of any right-lined figure, upon the base or side subtending it. It is likewise the perpendicular height of any object above the horizon; and is found several ways; by two staffs, a plain mirror with the quadrant, theodolite, or some graduated instrument &c.

HEIR, is he to whom lands, tenements, or hereditaments, by the act of God and right of blood, descend of some estate of inheritance.

Heir-*apparent*. Here we must observe, that no person can be heir until the death of his ancestor; yet in common parlance, he who stands nearest in degree of kindred to the ancestor, is called, even in his life-time, heir apparent. The law also takes notice of an heir apparent, so far as to allow the father to bring an action of trespass for taking away his son and heir, the father being guardian by nature to his son, where any lands descended to him.

Heir-*general*; the heir-general, or heir at common law, is he who after his father's or ancestor's death has a right to, and is introduced into, all his land, tenements, and hereditaments; but he must be of the whole blood, not a bastard, alien, &c. None but the heir-general, according to the course of the common law, can be heir to a warrantry, or sue an appeal of the death of his ancestors.

To prevent the wrong and injury to creditors by the alienation of the lands descended, &c. by 3 and 4 W. & M. c. 14. it is enacted, that in all cases where any heir at law shall be liable to pay the debt of his ancestor, in regard of any lands, tenements, or hereditaments descending to him, and shall sell, alien, and make over, the same before any action brought or process sued out against him, such heir at law shall be answerable for such debt or debts in action or actions of debt to the value of the said land so by him sold, alienated, or made over.

Heir-*looms*, are such goods and personal chattels as, contrary to the nature of chattels shall by special custom to the heir, along with the inheritance.

HEISTERIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is one species, a tree of Martinico.

HELIACAL, in astronomy, a term applied the rising or setting of the stars, or, more strictly speaking, to their emersion out of and immersion into the rays and superior splendor of the sun.

All the fixed stars in the zodiac, as also the superior planets, Mars, Jupiter, and Saturn, rise heliacally in the morning, a little before sun-rising, and a few days after they have set cosmically. They set heliacally in the evening a short time before their achronical setting But the moon, rises heliacally in the evening, after the new moon, and sets heliacally in the morning, when old and approaching to a conjunction with the sun.

The inferior planets, Venus and Mercury, which sometimes seem to go westward from the sun, and sometimes again have a quicker motion eastward, rise heliacally in the morning, when they are retrograde; but when direct in their motions, they rise heliacally in the [illegible]ing. The heliacal rising or setting of the moon happens when she is 17 degrees distant from the sun; but for the other planets 20° are required: and for the fixed stars more or less according to their magnitude.

HELIANTHUS, *the great sun-flower*, a genus of the polygamia frustanea order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. There are 12 species, most of which are now very common in our gardens, though all of them are natives of America.

HELIOCARPUS, a genus of the digynia order, in the dodecandria class of plants, and in the natural method ranking under the 37th order, columniferæ. There is one species, a tree of La Vera Cruz.

HELIOCENTRIC *latitude of a planet*, the inclination of a line drawn between the centre of the sun and the centre of a planet, to the plane of the ecliptic, which may be thus determined.

Heliocentric *place of a planet*, in astronomy, the place of the ecliptic which in the planet would appear to a spectator placed at the centre of the sun.

HELIOMETER, the name of an instrument for measuring with great exactness the diameters of the heavenly bodies, and especially those of the sun and moon. This instrument is a kind of telescope, consisting of two object-glasses of equal focal distance, placed one of them by the side of the other, so that the same eye-glass serves for both. The tube of this instrument is of a conical form, larger at the upper end, which receives the two object-glasses, than at the lower, which is furnished with an eye-glass and micrometer. By the construction of this instrument two distinct images of an object are formed in the focus of the eye-glass, whose distance, depending on that of the two object glasses from one another, may be measured with great accuracy.

HELIX, in geometry. See **Spiral**.

Helix, the *snail*, in zoology, a genus belonging to the order of vermes testacea. The shell consists of one spiral, brittle, and almost diaphanous valve; and the aperture is narrow. Of this genus more than three hundred species have been enumerated. H. formatia, a snail with five spires remarkably ventricose, slightly umbilicated, fasciated with a lighter and deeper brown, is found in the woods of the southern counties of England. It is used in many parts of Europe as food, particularly at Rome during

the weeks of Lent; here they are fattened, and grow to a very large size. H. hortensis, garden snail, has an imperforate shell, globular, pale, with broad interrupted brown bands; this species inhabits the garden and orchard in most parts of Europe; it abounds with a viscid slimy juice, which it readily gives out by boiling in milk and water, so as to render them thick and glutinous, and the compound, especially with milk, is reckoned efficacious in consumptive cases. Snails are very destructive to wall fruit: lime and ashes sprinkled on the ground will keep them away, and destroy the young brood. Fruit, already bitten, should not be taken off the tree, for they will not touch the other, till they have wholly eaten this, if left for them. Eyes of snails are lodged in their horns, one at the end of each horn, which they can retract at pleasure. Cutting off a snail's head, a little stone appears, which is supposed to be a great diuretic, and good in all nephritic disorders. So small an animal as the snail is not free from the plague of supporting other smaller animals; lice being found sometimes on the surface of its body, and worms within its intestines.

HELLEBORUS, *hellebore*, a genus of the polygynia order in the polyandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. There is no calyx; but five or more petals; the nectaria are bilabiated and tubular; the capsules polyspermous, and a little erect. There are seven species, the most remarkable of which is the niger, commonly called Christmas

HELM, in naval architecture, a long and flat piece of timber, or an assemblage of several pieces, suspended along the hind part of a ship's stern-post, where it turns upon hinges to the right or left, serving to direct the course of the vessel, as the tail of a fish guides the body. The helm is usually composed of three parts, viz. the rudder, the tiller, and the wheel, except in small vessels, where the wheel is unnecessary. The rudder is turned upon its hinges, by means of a long bar of timber called the tiller, which is fixed horizontally in its upper end within the vessel. The movements of the tiller to the right and left, accordingly direct the efforts of the rudder to the government of the ship's course as she advances. The operations of the tiller are guided and assisted by tackle, communicating with the ship's side, called the tiller-rope. In order to facilitate the management of the helm, the tiller rope, in all large vessels, is wound about a wheel which acts upon it with the powers of a crane or windlass.

HELMET, an ancient, defensive armour, worn by horsemen both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front secured by bars, which was called the visor.

It is still used in heraldry by way of crest over the shield or coat of arms, in order to express the different degrees of nobility by the different manner in which it is borne. Thus a helmet in profile is given to gentlemen and esquires: to a knight, the helmet standing forward, and the beaver a little open; the helmet in profile and open, with bars, belongs to all noblemen under the degree of a duke; and the helmet forward and open with many bars, is assigned to kings, princes, and dukes.

HELONIAS, a genus of the trigynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. There are two species, herbs of America.

HEMIMERIS, a genus of the angiospermia order, in the didynamia class of plants. There are three species, herbaceous plants of the Cape

HEMIONITIS, a genus of the natural order of filices, belonging to the cryptogamia class of plants. The fructifications are in lines, decussating or crossing each other. There are eight species, natives of the West Indies.

HEMIPTERA, derived from ἡμισος *half*, πτερον *wing*, in the Linnæan system, the second order of insects, comprehending twelve genera, viz. the blatta, mantis, gryllus, fulgora, cicada, notonecta, nepa, cimex, aphis, chermes, coccus, and thrips, and a great number of species.

HEMISPHERE, in geometry, the half of a globe or sphere, when it is supposed to be cut through its centre in the plane of one of its great circles. Thus the equator divides the terrestrial globe into the northern and southern hemisphere: in the same manner the meridian divides the globe into the eastern and western hemisphere; and the horizon into two hemispheres, distinguished by the epithets upper and lower.

Hemisphere, is also used to denote a projection of half the terrestrial globe, or half the celestial sphere, on a plane, and frequently called planisphere.

HEMISTICH, in poetry, denotes half a verse or a verse not completed. Of this there are frequent examples in Virgil's *Æneid*; but whether they were left unfinished by design or not, is disputed among the learned.

In reading common English verses, a short pause is required at the end of each hemistich, or half verse.

HEMLOCK. See Cicuta.

HEMP See Cannabis.

HEN. See Phasianus.

HENDECAGON, in geometry, a figure that has eleven sides, and as many angles. In fortification, hendecagon denotes a place defended by eleven bastions.

HEPTAGON, in geometry, a figure of seven sides and seven angles.

HEPTAGONAL *numbers*, in arithmetic, a sort of polygonal numbers, wherein the difference of the terms of the corresponding arithmetical progression is 5. Arithmeticals 1, 6, 11, 16, 21, &c.; and these added together, make heptagonals, 1, 7, 18, 34, 55, &c. One of the properties of these numbers is, that if they be multiplied by 40, and nine be added to the product, the sum will be a square number.

$$\begin{array}{rrcrcr}
\text{Thus} & 1 \times 40 + 9 & = & 49 & = & 7^2 \\
 & 7 \times 40 + 9 & = & 289 & = & 17^2 \\
 & 18 \times 40 + 9 & = & 329 & = & 27^2 \\
 & 34 \times 40 + 9 & = & 1369 & = & 37^2 \\
 & 55 \times 40 + 9 & = & 2209 & = & 47^2 \text{ \&c.}
\end{array}$$

HEPTARCHY, a government of seven persons: also a state or country divided into seven kingdoms, and governed by seven independent princes; in which sense it was particularly applied to the government of South Britain, when divided amongst the Saxons.

HERALD, is an officer at arms, whose business is to denounce war, proclaim peace, or be otherwise employed by the king in martial messages or other business.

Heralds are the judges and examiners of gentlemen's coats of arms, and preservers of

, and they marshal all solemnities nation of princes, and funerals of great persons.

HERALDRY, the science which teaches how to blazon, or explain in proper terms, all that belongs to coats of arms; and how to marshal, or dispose regularly, divers arms on a field.

Arms, or coats of arms, are hereditary marks of honour, made up of fixed and determined colours and figures, granted by sovereign princes, as a reward for military valour, or some signal public service performed. These are intended to denote the descent and alliance of the bearer, or to distinguish states, cities, societies, &c. civil, ecclesiastical, and military.

Men in all ages have made use of figures of living creatures, or symbolical signs, to denote the bravery and courage either of their chief or nation, to render themselves the more terrible to their enemies, and even to distinguish themselves or families as names do individuals.

The Heathen divinities had each their distinctive mark; Jupiter wielded the lightning in his right hand; Neptune bore the three pronged trident; Mars the spear; Saturn the scythe; and Bacchus the spear, encircled by ivy; the Phrygians, the sow; the Goths, a bear; the Thracians, Mars; the ancient French, the lion, which was afterwards changed to the toad, and that again for the fleur-de-lis, sent them from Heaven by an angel, whose commission was directed to Clovis, their first Christian monarch; the Saxons, a horse; the Flemings, a bull; the King of Antioch, an eagle grasping a dragon; the Romans, the eagle; Pompey, a lion holding a sword; yet the Roman people, who were saved by the cackling of geese, despised that bird in too great a degree to admit it into their ensigns; exclusive of the above, there were many nations and individuals who distinguished themselves by exhibiting every description of weapons on their banners. It should also be observed, that the most ferocious beasts and birds were selected as emblematic of honour and courage, for this reason, shields, with their figures only, are considered as most honourable and ancient; but those with trees, flowers, plants, the sun, moon, planets, varieties of colours, or charged with any of the honourable ordinaries, or artificial objects, are deemed of less importance.

The science of heraldry consists principally of blazoning and marshalling; the former is the art of displaying a coat of arms in its proper colours, the latter is the combining various arms in one shield. In blazoning it is usual to begin with the field, and then proceed with the charge, and in naming the objects charged in the field, to mention the most predominant, and next the field, first; and then the most remote. Gwillim observes, that tincture is a variable hue of arms, and as applicable to differences as to the arms, and is distributed into colours and

There are forms in heraldry, which have names only applied to them, and no colour specified in the blazoning; the term sufficiently explaining the colour of each; they resemble a globe or ball, and are called besants the colour or plates argent; hurts, azure; torteauxes, gules; pellets or ogresses, sable; pomeis, vert; golpes, purpure; oranges, tenne, and grosses, sanguine. In these nine varieties are included all the colours generally used in blazonry.

The blazoning of the arms of gentlemen, esquires, knights, and baronets, is derived from metals and colours: those of barons, viscounts, earls, marquisses, and dukes, from precious stones; and those of princes, kings, and emperors from the planets

Or, gold, is expressed by dots (see plate XXI Fig. I;) and is intended as an intimation, that as gold surpasses all other metals in value and purity, he that bears it should endeavour to excel in the same proportion, the same insinuation is implied in the topaz and the sun.

Argent, or white, is represented by a perfect blank (see figure 2), this colour ranks next to Or and without gold and silver Heraldry would be imperfect, argent signifies innocence, temperance, and hope, the pearl was supposed by the ancients to possess a restorative property, and Luna is acknowledged to be the mistress of honour, the seas, and tides.

Gules, red, is expressed by perpendicular line or lines paleways from the chief to the base (see fig. 3 :) this colour has ever been considered as symbolical of majesty and dignity; the ruby cannot be wasted by fire and water; and Mars, the planet, alludes to the heathen God of battle, the pattern of courage and military address.

Azure, blue, the lines in this instance are horizontal (see fig. 4,) and intended for the tint of the air or sky, and is said to denote loyalty, fidelity, and chastity; the precious stone and planet in azure were adopted as possessed of superior qualities, emblematic of the worth of nobles and princes.

Sable, or black, represented by perpendicular and horizontal lines crossing each other at right angles (see fig. 5.) Sable, indicates gravity, constancy, and grief for the loss of friends; the diamond is the most valuable of all stones, and Saturn presides over counsellors and other grave characters.

Vert, green, the lines are bendways (see fig. 6.) or from the sinister corner of the chief to the opposite of the base, and is emblematical of youth, peace, and concord.

Purpure, is a colour composed of a large part of crimson, and a less of blue, and the lines which express it tend directly contrary to those of vert, (see fig. 7.) this word is derived from the fish called purpura; the amethyst was preferred for its excellence to decorate the breast of Aaron, and the planet Mercury signifies goodness of temper.

Tenne, or tawny, is a mixture of red and yellow, and represented by lines like those of purpure, it has been but little used in England, but was formerly in a considerable degree in France.

Sanguine, is composed of a lake and a small quantity of Spanish brown, and expressed by lines as purpure, it was much used by the knights of the Bath, and by the sergeants at law in their vestments; the sardonix is said by St John to be the sixth stone in the Heavenly Jerusalem.

Furs are the next object to be considered, the use of which may be thus explained.

Ermine, implies a field argent, with the powdering sable. See fig. 8.

Ermines, is the reverse, or a field sable, and the powderings argent.

Erminois signifies a field or, and the powdering sable.

Pean, is a field sable, and the powderings or.

Vair, is of two descriptions: if it consists of argent and azure it is sufficient to say vair, but if it is compounded of any other colours, it is usual to say vairy of the colours adopted. See fig. 9.

Fig. 10 is blazoned potent-counter potent, and the colours argent and azure.

Doublings, of furs, were anciently, and are at present used for the linings of the robes and mantles, of senators, consuls, and kings.

The bordure is extended to a great variety, as (fig. 11.) gules a bordure, or; (fig. 12), a bordure indented, argent; (fig. 13) a bordure counter compone, argent and gules.

The bordure is generally one-sixth part of the breadth of the shield, and is ingrailed, indented, charged, componed, and countered. If the inner line of the bordure is strait and the latter plain, the colour of the bordure alone is named in blazoning; if it is charged with parts of plants or flowers, it is described as verdoy of trefoils. If it consists of ermines, vair, or vairy, or any of the furs, the heralds say purflew of ermines. When charged with martlets, charged with an enaluron of martlets.

The label is the first of the distinctive marks of the branches of a family, and is borne by the eldest son during the life of his father (see fig. 14.) The second son bears a crescent, the third a mullet, the fourth a martlet, the fifth an annulet, the sixth a fleur-de-lis, the seventh a rose, the eighth a cross moline, and the ninth a double quatrefoil. See figs. 15, 16, 17, 18, 19, 20, 21, 22.

In the second house, the first son bears a crescent charged with a label during his father's life only; the second son, of the same house, a crescent charged with another crescent; the third, a crescent charged with a mullet; the fourth, a crescent charged with a martlet; the fifth, a crescent charged with an annulet; and the sixth, a crescent charged with a fleur-de-lis.

The mullet, which is the difference of the third house, is thus charged: the first son, with a label during the life of his father; the second with a crescent; the third, with a mullet; the fourth with a martlet; the fifth, with an annulet: and the sixth, a fleur-de-lis.

The martlet, annulet, and fleur-de-lis, the differences of the fourth, fifth, and sixth houses, are charged for distinctions similar to the mullet.

The daughters of families are permitted to bear their father's arms, with the same distinctions used by them.

The shield, or escocheon, the mantle, the helmet, and crest, are the several parts of arms which compose an achievement. Accidents in the escocheon, are points and abatements; the former are places in the shield named according to their position in the middle, or remote, the middle are near the centre. The fess point is the centre of the escocheon. The honour point is in a direct line above it, and the nombril is next below it. Remote points are placed at still greater distances from the fess point, some of which are superior and others inferior; the former occupy the upper part of the escocheon, and of those there are middles and extremes, the middle is the exact middle of the chief between the two extremes; the two superior extreme points occupy the corners of the chief part of the escocheon, and are termed the dexter and sinister. The inferior points are at the base, and of them there are middle and remote, (see fig. 23) in which A is the dexter chief point, B, the precise middle chief; C, the sinister chief; D, the honour point; E, the fess point; F, the nombril point; G, the dexter base; H, the dexter middle base; I, the sinister base point. An abatement is a casual mark annexed to coat armour, which announces some dishonourable act of the bearer. Abatements consist of diminution and reversing, the first is the blemishing of some particular point of the escochoon by sanguine and tenne, which are stains: were the metals used they would be considered additions of honour. See fig. 24.

Augmentations are additional charges borne on an escocheon, a canton, or chief, and given as particular marks of honour. See fig. 26.

Escocheons are either of one or more tinctures; of those of more than one, that is said to be predominant, when some one metal colour or fur is supposed to be spread over the whole surface of the escocheon, which is termed the field, or shield; in such as have more than one tincture, the field and charge must be observed.

The charge is that which possesses the field, whether natural, artificial, vegetable or sensitive, and may be placed throughout the superfices, or in some particular part of the escocheon.

Ordinaries consist of lines variously drawn. The properties of them depend upon their deviations from a right line. Those are termed engrailed, invected, waved, crenelle, or embattled, nebule, indented, and dancette. (See fig. 27.) Of these, and straight lines, honourable ordinaries, abatements, and rewards of honour are composed.

The honourable ordinaries are the cross, chief, fess, barr, pale, chevron, bend, saltier, and escocheon.

The cross occupies the fifth part of the escocheon; if charged, the third; and is borne engrailed, invected, wavey, &c. between a charge, and charged as the rest of the ordinaries are. (See fig. 28.) Argent a cross sable.

The chief is peculiar to those who have obtained it by extraordinary merit: it contains one third part of the escocheon in depth, and is divided into a fillet, which includes a fourth part of the chief, and is placed in the chief point. (See fig. 29.) Or, a chief gules.

The fess is situated in the centre of the shield, and contains in breadth the third part of the escocheon. (See fig. 30. Azure a fess, or.) The bar differs from the fess only as it is but the fifth part of the shield. It is divided into the closet, or a moiety of the bar; and the barrulet, or half the closet.

The pale contains the third part of the escocheon, and is divided into a pallet, or one half of the pale. An endorse is the fourth part of a pale, and is not used but when the pale is between two of them. If the pale is upon an animal, it is usual to say, he is debrused with the pale, if the beast is on the pale, he is supported of the pale. (See fig. 31.) Gules a pale, or.

The chevron resembles the rafters of a house,

and occupies the fifth part of the field, and is divided into the chevronel, which contains half the chevron; and a couple close, the fourth part of the chevron. Those are not borne but in pairs, unless there is a chevron between them. (See fig. 32.) Gules, a chevron argent.

The bend contains the fifth part of the field in breadth when not charged; when charged, the third; and is divided into the bendlet, which is limited to the sixth part of the shield; into a garter, the moiety of a bend; into a cost, the fourth part of a bend; and a riband, the half of a cost. (See fig. 33.) Or, a bend azure.

There is, besides, the bend sinister, which passes obliquely across the escocheon, from the sinister chief to the dexter base. This is divided into the scrape, half the bend; and the battune, the fourth part of the bend, the most common badge of illegitimacy. (See fig. 34.) Gules, a battune argent.

The saltire contains the fifth part of the shield; if charged, the third. This object represents an ancient description of scaling ladder; and, similar to the other ordinaries, is borne engrailed, wavy, &c. &c. (See fig. 35.) Sable, a saltire embattled, counter embattled, argent.

An inescocheon consists of the fifth part of the field, and is to be placed in the fess point. Those who marry an heiress bear her arms on an escocheon of pretence. (See fig. 36.) Ermine, an inescocheon gules.

The pile is an ordinary, in form like a wedge; is an ancient addition to armoury, and adopted from the pointed instrument used to secure foundations on marshy grounds. (See fig. 37.) Azure, a pile ermine.

Partitions are such in which there is no tincture from metal, colour, or fur predominating in them, and are formed of various lines of partition, often causing counter-changing and transmutation. This kind of bearing may be engrailed, &c. (See fig. 38. Plate XXII)Parted per pale, argent and gules.

An example of counterchanges is given in fig. 39. Or, a cross per pale, gules and sable.

Another of ordinaries joined is shewn in fig. 40. Gules on a chevron argent, three bars, gemells sable.

The artificial objects used in heraldry are very numerous, and far too much so for enumeration: they express ensigns of dignity, both spiritual and temporal, the liberal and mechanical professions, and military and naval acts. See fig. 41.

Military figures are equally usual, and consist of castles, battering rams, daggers, spears, &c. &c.

Common charges are composed of objects natural or artificial; celestial are borne single, upon or between any of the honourable ordinaries, and then three are the usual number. (See fig. 42.) Diamond, a fess ermine, between three crescents topaz.

Under the article of vegetables are included trees, plants, leaves, flowers, and fruits. An illustration is given in fig. 43. Vert, five fig-leaves in saltier.

Various parts of the human body and the blood are borne in heraldry., (See fig. 44.) Argent, goutte de sang. These are, however, seldom borne alone, but upon or with some of the ordinaries. Goutte de sang only, always signifies gules; goutte de larmes, drops of tears azure, goutte d'eau, drops of water, argent, de poix, or sable, drops of pitch and d'or. The form of each is the same. The bloody hand is the appropriate mark of a baronet.

Of the various animals used, the lion is the most honourable; and all quadrupeds are considered more so than the bearings of fishes or fowls, particularly the males. The lion is borne rampant, (see fig. 45.) argent, a lion rampant sable; and passant, (see fig. 46.) or, a lion passant sable, in chief three piles of the second. Parts of the lion are also generally adopted. (See fig. 47.) Argent, a lion's head erazed vert. The varieties of beasts and their parts are extremely common, and cannot possibly be specified in an article so brief as the present. (See fig. 48.) Gules, a talbot passant, or, a chief ermine. All animals which are quadrupeds, and oviparous, may be borne. (See fig. 49.) Azure a tortoise erect, or. Fowls of every description are to be represented in the natural acts of standing or flying: those that are either whole footed, or have their feet divided, and have no talons, should be termed membered; the cock, and all birds of prey, must be called armed, and the arming or membering of them is to be of a different colour from the fowl or bird: in the blazoning of fowls which make much use of their wings, if they are not exhibited spread, they must be termed close. The parts and members are generally borne both couped and erazed, and that on or between any of the honourable ordinaries. Birds are considered a more noble bearing than fish. (See fig. 50.) Ermine, an eagle displayed gules.

Fishes are borne in many positions, directly upright, embowed, extended, and indorsed, and surmounting each other, fretted and triangle. (See fig. 51.) Azure, three trouts fretted in triangle argent. Those upright, with fins, were anciently termed in blazoning hauriant, signifying the act of respiration, to accomplish which fish frequently rise to the surface for fresh air; when borne transverse, or swimming, they were called in blazoning naiant. Fishes are borne in part, and on or between any of the honourable ordinaries.

There are, besides, animals or monsters, (See fig. 52.) Argent, a dragon's head erazed vert, holding in his mouth a sinister hand, couped at the wrist, gules.

Such are the peculiarities which distinguish the shield within the boundaries of its surface. We shall now proceed to treat of the helmet, and shew how it is placed in various cases, on the shield, above the coronet, and in others without the latter symbol of rank which equally marks the gradation of title with the helmet. The crown or coronet is more ancient than the helmet, and was invented as a testimony of triumph and victory; the radiated crown was assigned to emperors; but the coronet with pearls on the circle, and foliage intervening, was not used in heraldry more than 300 years past. (See fig. 53—56) the coronet of a Duke, Marquis, Earl, Viscount, and Baron; besides ducal, mural, naval, civic, celestial, custom, valary, &c.

The helmet was worn in battle, and at tournaments, both for use and distinction. Since the invention of fire arms it has been nearly confined to heraldic purposes. The manner of placing them on shields is shewn in figs. 57, 58, 59. Those right in front, many

bars, to sovereigns; those nearly in profile to peers; when front and open, to baronets and knights; in profile close, to esquires and gentlemen.

The wreath is a roll of silk, of two colours blazoned on the shield, and laid on the helmet as a support to the crest. See fig. 60.

The crest is the most elevated part of the armour of the head, and is said to be derived from *crista*, or cocks-comb. The original use appears to have been a protection from the edge of the sword, when aimed at the upper part of the skull. Gwillim asserts, that the crest, or cognizance, should possess the highest place next to the mantle, yet so as to permit the interposition of a scroll, wreath, chapeau, or crown. The knights who celebrated justs wore plumes, of the heron and ostrich feathers, with crests of various materials, which were altered at pleasure. They are of great antiquity, and were of superior honour, as no person was admitted to tilt at a just till he had given proof of his noble descent, and they were limited to those only, (see fig. 61) which exhibits a crest on the wreath.

The mantle is the drapery that is thrown around a coat of arms: it is doubled, or lined throughout by one of the furs.

Supporters are figures by the side of a shield, appearing as if they actually held it erect. (See fig. 62.) In England supporters are confined to peers, and knights of the four orders and proxies of the princes of the blood royal, at installations, except by an especial grant from the Sovereign.

HERALDS. The heralds, which are six in number, are distinguished by the names of Richmond, Lancaster, Chester, Windsor, Somerset, and York, and are all equal in degree, only preceding according to the seniority of their creation.

HERB, in botany, is that part of the plant which rises from the root, and is terminated by the fructification. It comprehends the trunk and stem; the leaves; the fulcra, or supports; and the buds, or, as they are sometimes denominated, the winter quarters of the future vegetable.

HERBACEOUS *plants*, in botany, are those which have succulent stems that die down to the ground every year; those are annual that perish every year; biennial, which subsist by the roots two years; perennial, which are perpetuated by their roots for a series of years.

HERCULES, in astronomy, a constellation of the northern hemisphere.

HEREDITAMENTS, all such things immoveable, whether corporeal or incorporeal, as a man may leave to him and his heirs, by way of inheritance; or which not being otherwise devised, naturally descend to him who is next heir of blood, and not to an executor or administrator, as chattels do. Hereditaments are of two kinds, corporeal and incorporeal. Corporeal hereditaments consist wholly of substantial and permanent objects, all which may be comprehended under the general denomination of land only. Incorporeal hereditaments are not the object of sensation, are creatures of the mind, and exist only in contemplation. They are principally of ten sorts, *viz.* advowsons, tithes, commons, ways, offices, dignities, franchises, presents, and rents.

HERMAPHRODITE, a term formerly applied exclusively to signify a human creature possessed of both sexes. The term is now applied to other animals, and to plants. It is now well known there is no such thing as an hermaphrodite in the human species. In most species of animals, the production of hermaphrodites appears to be the effect of chance; but in the black cattle it seems to be an established principle of their propagation. It is a well known fact, and, as far as has yet been discovered, appears to be universal, that when a cow brings forth two calves, one of them a bull, and the other a cow to appearance, the cow is unfit for propagation, but the bull-calf becomes a very proper bull. They are known not to breed; they do not show the least inclination for the bull, nor does the bull ever take the least notice of them. Among the country people in England, this kind of calf is called a free-martin; and this singularity is just as well known among the farmers as either cow or bull. When they are preserved, it is for the purposes of an ox or spayed heifer; *viz.* to yoke with the oxen, or fatten for the table.

HERMETICAL *seal*, among chemists, a method of stopping glass-vessels, used in chemical operations, so closely, that the most subtile spirit cannot escape through them. It is commonly done by heating the neck of the vessel in a flame, till ready to melt, and then twisting it close together with a pair of pincers.

HERNANDIA, in botany, a genus of the monœcia triandria class and order. Natural order of tricoccæ. Lauri, Jussieu. Ess. char. male, calyx three-parted; corolla three-petaled: female, calyx truncate, quite entire; corolla six-petaled; drupe hollow, with an open mouth, and a moveable nucleus. There are two species. H. sonora, whistling hernandia; and H. ovigera. egg-fruited hernandia.

HERNIARIA, *rupture-wort*, a genus of the pentandria digynia class and order of plants. Natural order of holoraceæ. Amaranthi, Jussieu. Calyx five-parted; corolla none; stamina five, barren, besides the fertile ones; capsule one-seeded. There are four species.

HERON. See Ardea.

HERRING. See Clupea.

HESPERIDÆ, the 19th order in Linnæus's Fragments of a natural method, consisting of five genera, among which are the caryophyllus or clove-tree; and the myrtus, myrtle; allspice or pimento. The plants of this order are of the shrub and tree-kind, and chiefly ever-green.

HESPERIS, *rocket* or *dames' violet*, a genus of the tetradynamia siliquosa class and order of plants. Natural order of siliquosæ. Cruciformes, Tournefort. Cruciferæ, Jussieu. Petals bent obliquely; a gland within the shorter stamens: siliqua stiff; stigma with a forked base, and converging tip; calyx closed. There are seven species.

HETEROGENEOUS, or *heterogeneal*, something that consists of parts of dissimilar kinds, in opposition to homogeneous.

Heterogeneous, in mechanics, such bodies whose density is unequal in different parts of their bulk; or they are such whose gravities in different parts are not proportionable to the bulks thereof.

Heterogeneous *quantities*, are those which are of such different kinds, as that one of them taken any number of times, never equals or exceeds the other.

HETEROSCII. See GEOGRAPHY.

HEUCHERA, in botany, a genus of the pentandria digynia class of plants, the corolla whereof consists of five petals; the fruit is an ovato-accuminated capsule; semibifid, terminating in two reflex points, and containing two cells. There are two species.

HEXACHORD, in ancient music, a concord called by the moderns a sixth.

HEXAEDRON, or *hexahedron*, one of the five regular or Platonic bodies; being indeed the same as the cube; and is so called from its having 6 faces.—The square of the side or edge of a hexahedron, is one third of the square of the diameter of the circumscribing sphere; and hence the diameter of a sphere is to the side of its inscribed hexahedron, as $\surd 3$ to 1.

HEXAGON, in geometry, a figure of six sides and angles; and if these sides and angles be equal it is called a regular hexagon. The side of every regular hexagon, inscribed in a circle, is equal in length to the radius of that circle. Hence, it is easy, by laying off the radius six times upon the circumference, to inscribe an hexagon in a circle. See GEOMETRY.

HEXAGON, in fortification, is a place defended by six bastions.

HEXAGYNIA, in botany, the name of an order of plants, consisting of those which, besides their classical character, have their flowers furnished with six styles.

HEXAMETER, in ancient poetry, a kind of verse consisting of six feet; the first four of which may be indifferently, either spondees or dactyls; the fifth is generally a dactyl, and the sixth always a spondee. Such is the following verse of Horace:

1 2 3 4 5 6
Aut pro|desse vo|lunt, aut|dele|ctare po|etæ.

HEXANDRIA, in botany, a class of plants, the sixth in order, comprehending all those plants which have hermaphrodite flowers, and six stamina in each.

HIBISCUS, *Syrian mallow*, a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is double, the exterior one polyphyllous, the capsule quinquelocular and polyspermous. Of this genus there are numerous species.

HIDES, the skins of beasts; but is particularly applied to those of large cattle, as bullocks, cows, buffaloes, horses, &c. Raw or green hide, is that which has not undergone any preparation. There are also hides dried in the hair. Salted hide, is a green hide seasoned with sea salt and alum, or salt-petre, to prevent its corruption. See TANNING and CURRYING.

HIDE *of land*, was such a quantity of land as might be plowed with one plough within the compass of a year, or so much as would maintain a family; some call it 60, some 80 and some 100 acres.

HIERACIUM, *hawkweed*, a genus of the polygamia æqualis order in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked, the calyx imbricated and ovate; the pappus simple and sessile. There are 55 species.

HIEROGLYPHICS, in antiquity, mystical characters, or symbols, in use among the Egyptians, and that as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments.

HIEROGLYPHICS, seem to have had their origin in the relation which, by the laws of creation, exists between things natural, or material, spiritual, or moral, and divine.

The meaning of a few of these hieroglyphics has been preserved by ancient writers. Thus we are told they represented the Supreme Deity by a serpent with the head of a hawk. The hawk itself was the hieroglyphic of Osiris; the river-horse, of Typhon; the dog, of Mercury; the cat, of the moon, or Diana; the beetle, of a courageous warrior; a new-born child, of the rising sun; and the like.

HIGHWAY, a public passage for the king's people; whence it is called the king's highway. It seems that anciently there were but four highways in England which were free and common to all the king's subjects, and through which they might pass without any toll, unless there were a particular consideration for it.

There are three kinds of ways, a foot-way, a pack and prime way, which is both a horse and foot way, and a cart way, which contains the other two. A river, common to all men, may also be called the king's highway; and that nuisances in any such ways are punishable by indictment.

If passengers have used, time out of mind, where the roads are bad, to go by outlets on the land adjoining to a highway in an open field, such outlets are parcels of the highway; and, therefore, if they are sown with corn, and the track is foundrous, the king's subjects may go upon the corn.

By the common law, the general charge of repairing all highways lies on the occupiers of the lands in the parish wherein they are. But it is said that the tenants of the lands adjoining are bound to scour their ditches.

Particular persons may be burdened with the general charge of repairing a highway, in two cases; in respect of an inclosure, or by prescription. As where the owner of lands not inclosed, next adjoining to the highway, incloses his lands on both sides thereof. But in all cases, whether a private person be bound to repair a highway by inclosure or prescription, the parish cannot take the advantage of it on the general issue, but must plead it specially.

At common law, it is said that all the country ought to make good the reparations of a highway, where no particular persons are bound to do it; because the whole county have their ease and passage by the said way.

By the ancient common law, villages are to repair their highways, and may be punished for their decay; and, if any do injury to, or straighten the highway, he is punishable in the King's Bench, or before the justices of peace in the court leet, &c Destroying any public turnpike-gate, or the rails or fences thereto belonging, subjects the offender to hard labour for three months, or to transportation for seven years.

Every justice of the peace, by the statute, upon his own view, or on oath made to him by the surveyor, may make presentment of roads being out of repair; and, thereupon, like process shall be issued as upon indictment.

HIGH *water*, the state of the tides when

they have flowed to the greatest height, or rather when they have ceased to flow. At this height the tides remain from 15 to 30 minutes before they begin to ebb again.

HIND, a female stag. See CERVUS.

HINGES, the joints on which gates, doors, lids, folds of tables, &c. hang and turn in opening, shutting, or folding; they are made either of iron or brass, are of different forms and uses, and are named accordingly.

HIP, in the materia medica, the fruit of the dog rose or wild briar.

HIPPIA, a genus of the polygamia necessaria order, in the syngenesia class of plants. There are three species, shrubs of the East Indies and the Cape.

HIPPOBOSCA, a genus of insects of the order diptera. The generic character is, mouth furnished with a bivalve, cylindric, obtuse, nutant snout; body depressed; feet furnished with several claws. This is not an extensive genus; the European hippoboscæ, scarcely affording more than five or six distinct species. Of these the most familiar is the hippobosca equina or horse-fly so troublesome to those animals, as well as to cattle, during the decline of summer, by its irritating motion, and by the pungent pain which its proboscis excites while in the act of suction. In size it varies in different districts, and seems to be largest in the southern climates.

HIPPOPOTAMUS, a genus of quadrupeds of the order of belluæ. The generic character is, the front teeth of the upper jaw are four, and placed in pairs; those of the lower jaw are prominent, and the intermediate ones are protruded forward; the canine teeth are single, and obliquely truncated; the teats are only two, and placed near the groin. It is a native of the warmer regions of the globe, and is chiefly found in the middle parts of Africa, inhabiting large rivers, and especially such as run through countries overshadowed by large forests; walking about at the bottom, and raising itself at intervals to the surface, for the purpose of respiration. By night it quits its watery residence, to graze in the neighbouring plains, devouring great quantities of herbage, destroying the more tender kind of trees and other vegetables. It is sometimes seen even in the sea, at some distance from the mouths of rivers, but this is supposed to be merely for the purpose of exercise; for it will not even drink salt water, and does not prey on fish, or indeed liv on any kind of animal food. The general of the hippopotamus seems to be nearly equal to that of the rhinoceros, and it is sometimes even superior. Its form is highly uncouth; the body being extremely large, fat, and round· the legs very short and thick; the head very large; the mouth extremely wide, and the teeth of vast strength and size, more particularly the tusks or canine teeth of the lower jaw, which are of a curved form: they sometimes measure more than two feet in length, and weigh upwards of six pounds each. The whole animal is covered with short hair, which is much more thinly set on the under parts than on the upper. The hippopotamus when just emerged from the water appears of a palish-brown, or mouse colour, with a blueish or slate coloured cast on the upper parts; and the belly is flesh coloured, the skin appearing through the hair. Its voice is a peculiar kind of interrupted roar, between that of a bull and the braying of an elephant. When on land it moves in a slow and aukward manner; but if pursued, can run with considerable speed, and directly plunging into the water sinks to the bottom and pursues its progress beneath. It is capable, notwithstanding its great bulk, of swimming very swiftly. Sometimes hippopotami are seen going in herds, or companies, to the distance of some miles from the bank of a river in quest of food. If wounded in the water they become furious, and are said to attack the boats or canoes whence the injury proceeded, and either overturn or sink them by biting out large pieces from the bottom. The hippopotamus sleeps in the small reedy islets which are found here and there in the rivers it frequents. In such spots it also brings forth its young; having only one at a birth, which it nurses with great care for a considerable time. The young is capable of being tamed, and we are assured by Belon that he saw one so gentle as to shew no inclination to escape, or to do any kind of mischief when let out of the stable in which it was kept.

These animals are said to be most successfully taken by preparing pitfalls for them, of large size, near the rivers. They are also occasionally shot, or killed with harpoons. Their flesh is reckoned good by the Africans, and the fat is said to be a fine kind of lard. But it is chiefly on account of the teeth, and more particularly of the tusks, that this animal is killed; their hardness being superior to that of ivory, at the same time that they are not so subject to become yellow, for which reason they are much used by the dentists.

HIPPURIS, *mare's tail*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the 15th order, inundatæ. There are three species, one a native of Britain, and which grows in ditches and stagnant waters.

HIRUDO, the *leech*, a genus of insects belonging to the order of vermes intestina. The body moves either forward or backward. There are 17 species, principally distinguished by their colour. The most remarkable are the following:

1. The *medicinalis*, or medicinal leech, the form of which is well known, grows to the length of two or three inches. The body is of a blackish-brown colour, marked on the back with six yellow spots, and hedged with a yellow line on each side; but both the spots and the lines grow faint, and almost disappear at some seasons. The head is smaller than the tail, which fixes itself very firmly to any thing the creature pleases. It is viviparous, and produces but one young at a time, which is in the month of July. It is an inhabitant of clear running waters, and is well known for its use in bleeding.

2. The *sanguisuga*, or horse-leech, is larger than the former. Its skin is smooth and glossy; the body is depressed, the back is dusky; and the belly is of a yellowish-green, having a yellow lateral margin. It inhabits stagnant waters.

3. The *geometra*, or geometrical leech, grows to an inch and a half in length; and has a smooth and glossy skin of a dusky-brown colour, but in some seasons greenish spotted with white. Its tail is remarkably broad; and it holds as firmly by it as by the head. It is common on stones in shallow running waters

and is often found on trout and other fish after the spawning season.

[illegible]

[illegible] horns, strongly annulated and rugged upon the rings, the tail delated. It inhabits the Atlantic ocean, and is by the fishermen called the sea-leech.

The mouth of the leech is armed with a sharp instrument that makes three wounds at once, and may be compared to the body of the pump, and the tongue or fleshy nipple to the sucker; by the working of this piece of mechanism the blood is made to rise up to the conduit which conveys it to the animal's stomach, which is a membranaceous skin divided into 24 cells.

The leech when fixed should be watched, lest it should find its way into the anus when used for the hemorrhoids, or penetrate into the œsophagus if employed to draw the gums, as it would make great havoc in the stomach or intestines. In such a case, the best and quickest remedy is to swallow some salt; which is the method practised to make it loose its hold when it sucks longer than was intended.

HIRUNDO, in ornithology, a genus of birds of the order of passeres. There are 37 species, chiefly distinguished by their colour. The most remarkable are,

1. The *rustica*, common or chimney swallow, is distinguished from all the other species by the superior forkiness of its tail, and by the red spot on the forehead and under the chin. The crown of the head, the whole upper part of the body, and the coverts of the wings, are black, glossed with a rich purplish blue, most resplendent in the male: the breast and belly white, and in the male tinged with red. The food of this swallow is insects. For the taking of these, nature has admirably contrived their several parts: their mouths are very wide to take in flies, &c. in their quickest motions; their wings are long, and adapted for distant and continual flight; and their tails are forked, to enable them to turn the readier in pursuit of their prey. This species is the first comer of all the British hirundines; and appears in general on or about the 13th of April, though now and then a straggler is seen much earlier. Each species of hirundo drinks as it flies along, sipping the surface of the water; but the swallow alone, in general, washes on the wing, by dropping into a pool for many times together: in very hot weather house-martens and bank-martens dip and wash a little.

2. The *esculenta*, or edible swallow, according to Buffon, is less than the wren, and only two inches and a quarter in length. The bill is black; the upper parts of the body are brown, the under whitish; the tail is forked, and each feather of it is tipped with white; the legs are brown.

The most curious part of the natural history of this bird consists in the nest, which is composed of such materials as render it not only edible, but one of the greatest dainties of the Asiatic epicures.

3. The *urbica*, or marten, is inferior in size to the chimney swallow, and its tail much less forked. The head and upper part of the body, except the rump, are black, glossed with blue; the breast, belly, and rump, are white: the feet are covered with a short white down. This is the second of the swallow kind that appears in our country. They begin to appear about the

[illegible]

[illegible] flights about which they almost obscure by their numbers the face of the sky. Unless these birds are very short-lived indeed, or unless they do not return to the district where they were bred, they must undergo vast devastations somehow, and somewhere; for the birds that return yearly bear no manner of proportion to the birds that retire.

4. The *riparia*, sand-marten, or shore-bird, is 4¾ inches in length, with the whole upper parts of the body of a mouse colour, the throat and under parts white, the bill and legs blackish. It is common about the banks of rivers and sand-pits, where it terebrates a round and regular hole in the sand or earth, which is serpentine, horizontal, and about two feet deep.

5. The *apus*, or swift, is a large species, being near eight inches long, with an extent of wing near 18 inches, though the weight of the bird is only one ounce. Their feet are so small, that the action of walking and rising from the ground is extremely difficult; but nature has made it full amends, by furnishing it with ample means for an easy and continual flight. It rests by clinging against some wall, or other apt body. It breeds under the eaves of houses, in steeples, and other lofty buildings; and makes its nest of grasses and feathers.

The swift is a summer inhabitant of these kingdoms. It comes the latest, and departs the soonest, of any of the tribe.

6. The *melba;* or white bellied swift, is in length eight inches and a half, and weighs two ounces five drams.

7. The *cayennensis*, or white coloured swallow, is about the size of the martin: the head and bill are black; the chin and throat white, passing from the last in a narrow collar round the neck: between the bill and the eye is a streak of white; the rest of the plumage is black, with a gloss of violet.

By the myriads of insects which every single brood of swallows destroys in the course of a summer, they defend us in a great measure from the personal and domestic annoyance of flies and gnats; and, what is of more consequence, they keep down the numbers of our minute enemies, who, either in the grub or winged-state, would otherwise render the labours of the husbandman fruitless.

HISTORY, *civil.* History, in its simplest definition, implies the mere narration of events and facts; but when placed in its true dignity, it is something more than this, it is philosophy "teaching by examples." The study of it is more or less the employment of all persons of reading and education; and the composition of it was the earliest use that was made of letters, since the first poems were historical: it is calculated for the use of all ranks and all professions in life, and places the reader of its events as a spectator out of all hazards, who may reap wisdom from the danger of others, and foretel, to a certain extent, the future by the past.

The general uses of history are exhibited by Dr. Priestley under three heads: 1. He says, history serves to amuse the imagination, and interest the passions in general. 2. It improves the understanding: and 3. It tends to strengthen

the sentiments of virtue. In the first of these views we find history has a great advantage over every work of fiction; for we consider it as the voice of truth. The second has been aptly illustrated by Bolingbroke, who observes, that "He who studies history as he would philosophy, will distinguish and collect certain general principles and rules of life and conduct, which always must be true, because they are conformable to the invariable nature of things; and by doing so he will soon form to himself a general system of ethics and politics on the surest foundations, on the trial of these principles and rules in all ages, and on the confirmation of them by universal experience." And the third is still more evident, from the very light in which characters and events are seen in it. Fame is found just to the dead, however partial to the living.

In regard to what is necessary or useful to be known previous to the study of history, it is proper to observe, that it must be taken in very different degrees of extent, according to the views with which history is read; and these depend very much upon the age and situation of the person who applies to it. But whoever proposes to study history scientifically, must come to the reading of it furnished with the first principles of certain sciences. If not the knowledge, at least a general idea of the principles of human nature, will be an excellent guide to us in judging of the consistency of human characters, and of what is within and what is without the reach of human powers. Philosophical knowledge, in general, will be found of the most extensive use to all persons who would examine with accuracy the achievements of ancient nations in peace or war, or who would thoroughly weigh the accounts of any thing in which the powers of nature are employed. But those sciences which are of the most constant and general use are geography and chronology.

To enumerate all the modern compilations of ancient history which may be serviceable to those who cannot make their searches in the original authors would be endless. That of Rollin must not be passed over. The most complete body of history, however, ancient and modern, is the Universal: which has references to the original writers for almost every paragraph of information. Gillies and Mitford have written Histories of Greece, and Hooke is by far the most preferable among the compilers of the Roman history.

Let it be remembered that in this country, it is an indispensable duty of every man of liberal birth, to be acquainted in a certain degree with the science of politics. History is the school of politics; it unfolds to us the springs of human affairs; the causes of the rise, grandeur, revolutions, and fall of empires. It points out the reciprocal influence of government and of national manners: it dissipates prejudices, nourishes the love of our country, and directs to the best means of improvement. It illustrates equally the blessings of political union and the miseries of faction.

HITCH, in the sea-language, is to catch hold of any thing with a hook or rope, and by this means to hold it fast: thus when a boat is to be hoisted in, the sailors say, hitch the tackles into the ring-bolts of the boat.

HIVE, in country affairs, a convenient receptacle for bees. See Apis.

HOARSENESS. See Medicine.

HODMAN, an appellation given to a young student admitted into Christ's College, Oxford, from Westminster-school.

HOE, a husbandman's tool, somewhat like a cooper's adze to cut up weeds in gardens, fields, &c.

HOEING, in the new husbandry, is the breaking or dividing the soil by tillage while the corn or other plants are growing thereon. It differs from common tillage in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments.

HOG. See Sus.

HOGSHEAD, in commerce, a measure of capacity, containing sixty-three gallons.

HOLCUS, Indian millet or corn; a genus of the monœcia order, in the polygamia class of plants; and in the natural method ranking under the 4th order, gramina. The male calyx is a bivalved glume; there is no corolla, but three stamina. Of this genus there are fifteen species, two of which are natives of Britain.

HOLD, that part of a ship which lies between the keelson and the lower deck; in which, divided by bulk heads, are the steward's room, powder-room, bread-room, and the boat-swain's and carpenter's store-rooms. In a merchantman, all the goods and lading in general, are stowed in the hold.

HOLLAND, in commerce, a fine and close kind of linen, so called from its being first manufactured in Holland.

HOLLY. See Ilex.

HOLOCENTRUS. Holocentrus, a genus of the order thoracici; the generic character is, habit of the genus perca; gill-covers scaly, serrated, and aculeated; scales in most species, hard and rough. There are about thirty-five species.

HOLOSTEUM, a genus of the trigynia order, in the triandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is pentaphyllous; the petals five; the capsule unilocular, and nearly cylindrical, opening at top. There are five species.

HOMALIUM, a genus of the class and order polyandria trigynia. The calyx is six or seven-parted: corolla six or seven-petalled: stamina, 21 in three bodies: pericarpium, one-celled, many-seeded: there are two species, a tree of Jamaica, and a shrub of Guiana.

HOMICIDE, properly so called, is the killing of a man by a man. Of this there are several species, as homicide by self-defence, homicide by misadventure, justifiable homicide, manslaughter, chance-medley, and murder.

Homicide by self-defence. Homicide se defendendo, or in a man's own defence, seems to be, where one has no other possible means of preserving his life from one who combats with him on a sudden quarrel, and kills the person by whom he is reduced to such inevitable necessity.

Homicide by misadventure, is where a man in doing a lawful act without any intent of hurt, unfortunately chances to kill another, as where a labourer being at work with a hatchet, the

head thereof flies off, and kills one who stands by

It seems clear, that neither homicide by misadventure, nor homicide se defendendo are felonious, because they are not accompanied with a felonious intent, which is necessary in every felony.

Justifiable homicide. To make homicide justifiable, it must be owing to some unavoidable necessity, to which a person who kills another must be reduced, without any manner of fault in himself.

Justifiable homicide of a public nature is such as is occasioned by the due execution or advancement of public justice.

Manslaughter. Homicide against the life of another, is either with or without malice; that which is without malice is called manslaughter, or sometimes chance medley, by which is understood such killing as happens on a sudden quarrel.

The only difference between murder and manslaughter is, that murder is upon malice aforethought, and manslaughter upon a sudden occasion, as if two meet together, and striving for the wall the one kills the other, this is manslaughter and felony.

Chance or chance-medley. Authors of the first authority disagree about the application of this word; by some it is applied to homicide by misadventure, by others to manslaughter.

Murder is the highest crime against the law of nature, that a man is capable of committing. It is when a man of sound memory, and at the age of discretion, unlawfully kills another person under the King's peace with malice aforethought, either expressed by the party, or implied by the law, so as the party wounded or hurt, die of the wound or hurt within a year and a day, the whole day on which the hurt was done, being reckoned the first.

The law so far abhors all duelling in cold blood, that not only the principal who actually kills the other, but also his seconds are guilty of murder, whether they fought or not; and it is holden that the seconds of the person killed, are also equally guilty, in respect to the countenance which they give to their principals in the execution of their purpose, by accompanying them therein, and being ready to bear a part with them.

HOMOGENEOUS, or *homegeneal*, an appellation given to things, the parts of which are similar or of the same nature and properties.

Homogeneous *light*, that whose rays are all of one colour and degree of refrangibility, without any mixture of others. See the article Colour.

Homogeneous *surds*, those which have the same radical character, or signs, as $\sqrt[2]{a}$, and $\sqrt[2]{b}$. See the article Surd.

HOMOLOGOUS, in geometry, an appellation given to the corresponding sides and angles of similar figures, as being proportional to each other.

All similar figures have their like sides homologous, or proportional to one another: their areas also are homologous, or proportional to the squares of the like sides, and their solid contents are homologous or proportional to the cubes of the same.

HONE, a fine kind of whetstone, used for setting razors, pen-knives, and the like.

HONEY is a vegetable product very similar in its properties to sugar. It is found in large quantities in a number of vegetables, is collected by the bee, and fed upon by many insects. It is always formed in the flower, chiefly at the base of the pistil. Honey differs much in colour and in consistence: it contains much saccharine matter, and probably some mucilage, from which it derives its softness and viscosity. Honey yields a strong liquor called *Mead.* There are two species of honey; the one is yellow, transparent, and of the consistence of turpentine; the other white, and capable of assuming a solid form. These two species are often united. In France, a good swarm of bees, in two years, will yield nearly thirty pounds of honey; and they are still more profitable in countries that are covered with flowers the greater part of the year. The white or virgin honey trickles out spontaneously from the combs. These they break soon after they are made, and lay them upon hurdles or mats of osier, or on linen cloth, and an excellent white honey will fall from the combs, and grow hard in a short time. Afterward they put them into glazed earthen pots. Honey produced in mountainous countries is more highly flavoured than that in low grounds. The honey made in the spring is more esteemed than what is gathered in the summer; that of the summer more than that of the autumn. There is also a preference given to that of young swarms. Honey is the production of most countries; yet more abundant in the island of Candia, and in the greater part of the islands of the Archipelago, than any where else. The Sicilian honey seems to be particularly high flavoured. Considerable quantities of honey are produced by the wild bees in the woods of North America. See Apis.

HONOUR signifies a testimony of esteem or submission, expressed by words, actions, and exterior behaviour, by which we make known the veneration and respect we entertain for any one on account of his dignity or merit. The word is also used for the esteem due to virtue, glory, and reputation. It is also used for *virtue* and *probity* themselves, and for an exactness in performing whatever we have promised, in which last sense we use the term *a man of honour.* But honour is more particularly applied to the two different kinds of virtue; bravery in men, and chastity in women.

HONOUR, in law, is used especially for the more noble sort of seigniories on which other inferior lordships or manors depend, by performance of some customs or services to those who are lords of them.

Honour, *courts of.* There is a court of honour of earl marshal of England, &c. which determines disputes concerning precedency and points of honour.

Honours, *military;* all armies salute crowned heads in the most respectful manner, colours and standards dropping, and officers saluting. Different ranks of officers are saluted in a different mode.

Honours *of war*, are stipulated terms which are granted to a vanquished enemy, and by which he is permitted to march out of a town, from a camp, or line of entrenchments, with all the insignia of military etiquette.

HOP. See Humulus.

HOPEA, a genus of the polyandria order, in

the polyadelphia class of plants. There is only one species, the tinctoria, a native of Carolina.

HORARY *circle*. See GLOBE.

HORARY *motion of the earth*, the arch it describes in the space of an hour, which is nearly 15 degrees, though not accurately so, as the earth moves with different velocities, according to its greater or lesser distance from the sun.

HORD, in geography, a company of wandering people, which have no settled habitation, but stroll about, dwelling in waggons or under tents, to be ready to shift as soon as the herbage, fruit, and the present province is eaten bare; such are several tribes of the Tartars, particularly those who inhabit beyond the Wolga, in the kingdoms of Astracan and Bulgaria.

HORDEUM, *barley*, a genus of the triandria-trigynia class of plants, the corolla whereof consists of two valves; the inferior valve is angular, of an ovato-acuminated figure, bellied, and longer than the cup, and terminates in a very long arista; the anterior valve is lanceolated, plane, and smaller: the corolla serves as a pericarpium, surrounding the seed, and not letting it out; the seed is oblong, ventricose, pointed at each end, and marked with a longitudinal furrow.

HORIZON. See ASTRONOMY and GEOGRAPHY.

HORIZONTAL *dial*. See DIALLING.

HORIZONTAL *line*. See PERSPECTIVE.

HORIZONTAL *plane*, that which is parallel to the horizon of the place, or nothing inclined thereto. The business of levelling is to find whether two points are in the horizontal plane, or how much the deviation is.

HORIZONTAL RANGE *of a piece of ordnance*, is the distance at which it falls on or strikes the horizon, or on a horizontal plane, whatever is the angle of elevation or direction of the piece. See GUNNERY.

HORN. An animal substance, chiefly membranous, composed of coagulated albumen, with a little gelatin, and about half a per cent of phosphate of lime. But the horns of the buck and hart are of a different nature, being intermediate between bone and horn.

HORN is also a musical instrument of the wind kind, chiefly used in hunting, to animate the hunters and the dogs, and to call the latter together. The French horn is bent into a circle, and goes two or three times round, growing gradually larger and wider towards the end, which in some horns is nine or ten inches over.

HORNS *of insects*, the slender oblong bodies projected from the heads of those animals, and otherwise called antennæ or feelers.

HORN *ore*, in mineralogy, is one of the species of silver ore; its most frequent colour is pearl-grey, of all degrees of intensity, which borders sometimes on milk-white, and sometimes approaches to lavender and violet-blue. It passes also, though but rarely, into green. It is found massive, disseminated in thick membranes, in roundish hollow balls; also crystallized: specific gravity 4.8. When heated on charcoal before the blow-pipe, it melts quickly, and leaves a globule of silver; it is even fusible by the flame of a candle; it takes a polish by friction; and its constituent parts, according to Klaproth, are

Silver	67.75
Muriatic acid	21.
Sulphuric acid	0.25
Oxide of iron	6.0
Alumina	1.75
Lime	0.25
	97.00
Loss	3.00
	100.00

It occurs in veins, and generally in their upper parts, and is usually accompanied with brown iron ochre, and with silver glance, but seldom with native silver and red silver ore.

HORN *stone*, or HORN *steen*, in mineralogy, a species of the flint genus, divided by Werner into three sub-species: the splintery, the conchoidal, and the wood-stone. The most common colour of the splintery horn-stone is grey; it is found in veins, in the shape of balls, in lime-stone, and forming the basis of porphyry, in several parts of Germany, and also in the Shetland islands. It appears to differ from quartz in containing a greater proportion of alumina; when it contains a very large quantity, it passes into jasper. It sometimes borders on chalcedony and flint. The best mill-stone, called French bur, is cellular-splinter hornstone. Conchoidal hornstone occurs in beds, accompanied with agate, and is distinguished from the splintery by the lightness of its colours, its fracture, and its inferior translucency and hardness.

In the wood-stone several colours occur together, and it commonly exhibits coloured delineations, as clouded and striped, and these arrange themselves in the direction of the original woody texture.

HORNBLENDE. A sub-species of straight-edged augite. There are three varieties of hornblende: the common, hornblende-slate, and basaltic hornblende.

1. *Common hornblende*. Colour, greenish-black, and black of other shades. Massive disseminated and crystallized, in a broad, thin, very oblique, four-sided prism, and in a six-sided prism. The lateral planes of the prism are deeply longitudinally streaked. Lustre shining, pearly. Cleavage twofold and oblique angular. Fracture uneven. The black hornblende is opaque, the green translucent on the edges. Harder than apatite, but not so hard as felspar. Mountain-green streak. When breathed on, it yields a peculiar smell. Difficultly frangible. Sp. gr. 3.25. It melts before the blowpipe, with violent ebullition, into a greyish-black coloured glass. Its constituents are, 42 silica, 12 alumina, 11 lime, 2.25 magnesia, 30 oxide of iron, 0.25 ferruginous manganese, and 0.75 water, with a trace of potash. It is an essential ingredient of the mountain rocks, syenite, and greenstone, and it occurs frequently in granite, gneiss, &c. It is found abundantly in the British Islands, and on the Continent.

2. *Hornblende-slate*. Colour intermediate between greenish-black, and blackish-green. Massive. Lustre glistening, or pearly. Fracture straight slaty. Fragments tabular. Opaque. Streak greenish. Semi-hard Difficultly fran-

gible. It occurs in beds in gneiss, in Aberdeenshire, Banffshire, and Argyllshire, in many parts of England and Ireland, and abundantly on the Continent.

3. *Basaltic hornblende.* Colour, velvet-black, or brownish-black. It occurs crystallized, in the following figures: an unequiangular six-sided prism; and the six-sided prism both variously acuminated. Lustre of the cleavage, which is double, is splendent, approaching to pearly. Fracture small grained uneven. Opaque. Rather harder than common hornblende, and more easily frangible. Streak dark greyish-white. Sp. gr. 3.16. It fuses into a black glass. Its constituents are, 47 silica, 26 alumina, 8 lime, 2 magnesia, 15 oxide of iron, and 0.5 water. It occurs imbedded in basalt, along with olivine and augite at Arthur's Seat, near Edinburgh, in Fifeshire, and the Islands of Mull, Canna, Eigg, and Skye.

HORNET. See Vespa.

HOROLOGY. For a description of the article of clock-work the reader has been referred to *horology*, under which it was our intention to treat of it; but for the sake of more effectually equalizing the alphabetical arrangement of the work we have resolved to introduce it under the article Watchwork, which See.

HORSE. See Equus.

Horse-*dealers*. Every person exercising the trade or business of a horse-dealer, must take out a licence from the stamp-office. Horse-dealers who shall carry on the said business without having obtained a licence under this act, shall be liable to be assessed the duties on riding-horses, and shall deliver lists thereof as other persons.

HORSES. It shall be lawful for any person, native or foreigner, at any time to ship, lade, and transport by way of merchandize, horses into any parts beyond the seas in amity with his majesty, paying for each horse, mare, or gelding, 5*s*. and no more.

No person convicted of feloniously stealing a horse, gelding, or mare, shall have the privilege of clergy. 1. Edw. VI. c. 12. And not only all accessaries before such felony done, but also all accessaries after such felony, shall be deprived and put from all benefit of their clergy, as the principal, by statute heretofore made, is or ought to be.

If a horse be stolen out of the stable, or other curtilage of a dwelling-house, in the night time, it falls under the denomination of burglary; if in the day-time, it falls under the denomination of larceny from the house. Where any person shall in the night-time maliciously, unlawfully and willingly kill or destroy any horses, sheep, or other cattle, of any person, every such offence shall be adjudged felony, and the offender shall suffer as in the case of felony.

If a man rides to an inn, where his horse has eaten, the host may detain the horse till he is satisfied for the eating, and without making any demand.

HORTUS *ciccus*, a *dry garden*, an appellation given to a collection of specimens of plants, carefully dried and preserved. The value of such a collection is very evident, since a thousand minutiæ may be preserved in the well-dried specimens of plants, which the most accurate engraver would have omitted.

Among the different methods adopted by botanists for obtaining a hortus ciccus, the following appear to be the most practicable:—Plants may be dried by pressing in a box of sand, or with a hot smoothing iron. Each of these has its advantages. If pressure be employed, a botanical press may be procured. The press is made of two smooth boards of hard wood, eighteen inches long, twelve broad, and two thick. Screws must be fixed to each corner with nuts. If a press cannot easily be had, books may be employed. Next some quires of unsized blotting paper must be provided. The specimens, when taken out of the tin box, must be carefully spread on a piece of pasteboard, covered with a single sheet of the paper quite dry; then place three or four sheets of the same paper above the plant, to imbibe the moisture as it is pressed out; it is then to be put into the press. As many plants as the press will hold may be piled up in this manner. At first they ought to be pressed gently. After being pressed for twenty-four hours or so, the plants ought to be examined, that any leaves or petals which have been folded may be spread out, and dry sheets of paper laid over them. They may now be replaced in the press, and a greater degree of pressure applied. The press ought to stand near a fire, or in the sunshine. After remaining two days in this situation, they should be again examined, and dry sheets of paper be laid over them. The pressure then ought to be considerably increased. After remaining three days longer in the press, the plants may be taken out, and such as are sufficiently dry may be put in a dry sheet of writing-paper. Those plants which are succulent may require more pressure, and the blossom paper again renewed. Plants which dry very quickly, ought to be pressed with considerable force when first put into the press; and if delicate, the blossom-paper should be changed every day. When the stem is woody, it may be thinned with a knife, and if the flower be thick or globular as the thistle, one side of it may be cut away; as all that is necessary, in a specimen, is to preserve the character of the class, order, genus, and species. Plants may be dried in a box of sand in a more expeditious manner, and this method preserves the colour of some plants better. The specimens, after being pressed for ten or twelve hours, must be laid within a sheet of blossom-paper. The box must contain an inch deep of fine dry sand, on which the sheet is to be placed, and then covered with sand an inch thick; another sheet may then be deposited in the same manner, and so on, till the box be full. The box must be placed near a fire for two or three days. Then the sand must be carefully removed, and the plants examined. If not sufficiently dried, they may again be replaced in the same manner for a day or two. In drying plants with a hot smoothing iron, they must be placed within several sheets of blotting paper, and ironed till they become sufficiently dry. This method answers best for drying succulent and mucilaginous plants. When properly dried, the specimens should be placed in sheets of writing-paper, and may be slightly fastened by making the top and bottom of the stalk pass through a slip of the paper, cut nearly for the purpose. Then the name of the genus and species should be written down, the place where it was found, nature of the soil, and the season of the year.

HOT-*beds*, in gardening, beds made with

fresh horse-dung, or tanners bark, and covered with glasses to defend them from cold winds. According to the quantity and quality of the materials put together for hot-beds, the heat will be proportioned as to strength and duration. The place where hot-beds are worked should be open to the full sun, catching it as early as possible in the morning, and having it as long as can be in the evening; and if not naturally sheltered, it should be screened from the north and north-east winds by a boarded fence or rather one of reeds, as from a solid fence the wind reverberates. Working of the dung is necessary previous to the making of a hot-bed, *i. e.* it should be thrown together on a heap, in a conical form; and when it has taken a thorough heat, and has been smoaking for two or three days, it should be turned over, moving the outside in, or mixing the colder parts with the hot. When it has taken heat again for two or three days, give it a second turn as before, and having lain the same time, it will be in proper order for making a good lasting bed with a steady heat.

HOT-*house,* in gardening, an erection for the culture of the tender exotics of tropical climates. It is generally built lower than a green-house, with double flues, and a pit in the middle for tanners' bark, in which, as in a kind of hot-bed, the pots containing the plants are to be set. A south-west aspect is found to be the most suitable for an erection of this kind, as by an economical use of the sun's rays, much of the expense of heating may be saved.

HOVERING. Ships of 50 tons, laden with customable or prohibited goods, hovering on the coasts of this kingdom, within the limits of any port (and not proceeding from foreign parts,) may be entered by officers of the customs, who are to take an account of the lading, and to demand and take a security from the master, by his bond to his majesty, in such sum of money as shall be treble the value of such foreign goods then on board; that such ship shall proceed, as soon as wind and weather, and the condition of the ship will permit, on her voyage to foreign parts.

HOUND. See CANIS.

HOUR, *hora,* in chronology, an aliquot part of a natural day, usually a 24th, sometimes a 12th. See ASTRONOMY, GEOGRAPHY, &c.

There are different hours used by chronologers, astronomers, dialists, &c. Sometimes hours are divided into equal and unequal. Equal hours are the 24th part of a day and night precisely, that is, the time wherein 15 degrees of the equator mount above the horizon. These are also called equinoctial hours, because they are measured on the equinoctial; and astronomical, because used by astronomers. They are also differently denominated according to the manner of accounting them in different countries. Astronomical hours are equal hours, reckoned from noon or mid-day, in a continued series of twenty-four. Babylonish hours are equal hours reckoned in the same manner from sun-rise. The Italian hours are also equal hours, reckoned in the same manner too, from the sun-setting. European hours are also equal hours, reckoned from midnight; 12 from thence to noon, and 12 more from noon to midnight. Jewish, or planetary, or ancient hours, are the twelfth part of the artificial day and night, each being divided into 12 equal parts. Hence, as it is only in the time of the equinoxes that the artificial day is equal to the night, it is then only that the hours of the day are equal to those of the night. At other times they will be always either increasing or decreasing: and they will be the more or less unequal according to the obliquity of the sphere.

HOUR *glass,* a popular kind of chronometer, which serves to measure the flux of time by the running of sand from one vessel into another. Glasses of this kind for half and quarter hours, and for less divisions of time are much used at [illegible]

HOUSE, in astrology, denotes the twelfth part of the heavens. The division of the heavens into houses, is founded upon the pretended influence of the stars, when meeting in them, on all sublunary bodies. These influences are supposed to be good or bad, and to each of these houses particular virtues are assigned, on which astrologers prepare and form a judgment of their horoscopes.

HOUSE, a habitation, or place built with conveniences for dwelling in. See ARCHITECTURE.

The word is also used to designate a noble family, or a race of illustrious persons descended from the same stock. Thus we say, the house or family of the Stuarts, the Bourbons, the house of Hanover, &c

HOUSEHOLD, the whole of a family considered collectively, including the mistress, children, and servants; but the household of a sovereign prince includes only the officers and domestics belonging to his palace.

The principal officers of his majesty's household are, the lord steward, lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse.

HUDSONIA, a genus of the monogynia order, in the dodecandria class of plants. There is no corolla; the calyx is pentaphyllous and tubular; there are 15 stamina; the capsule is unilocular, trivalvular, and trispermous. These is one species, a shrub of Virginia.

HUE AND CRY, is the ancient common law process after felons, and such as have dangerously wounded any person, or assaulted any one with intent to rob him; and it has received great countenance and authority by several acts of parliament. For the levying of hue and cry, although it is a good course to have a justice's warrant, where time will permit, in order to prevent causeless hue and cry; yet it is not necessary nor always convenient, for the felon may escape before the warrant is obtained.

HUER, a name given to certain fountains in Iceland, of a most extraordinary nature, forming at times jets d'eaux of scalding water 94 feet high and 30 in diameter. They arise out of cylindrical tubes of unknown depths. Near the surface they expand into apertures of a funnel shape, and the mouths spread into a large extent of stalactical matter, formed of successive scaly concentric undulations. The playing of these stupendous spouts is foretold by noises roaring like the cataract of Niagara

HUGONIA, a genus of the decandria order in the monadelphia class of plants, and in the natural method ranking with those of which the order is doubtful. There is one species, a tree of the East Indies.

HUGUENOTS, a name given by way of contempt to the protestants of France, in the year 1560; but authors are not agreed as to its origin. The most plausible opinion, however, is that of Pasquier, who observes, that at Tours, the place where they were first thus denominated, the people had a notion that an apparition or hobgoblin, called king Hugon, strolled about the streets in the night-time; whence as those of the reformed religion met chiefly in the night to pray, &c. they called them Huguenots, that is, the disciples of king Hugon.

HULL, in the sea-language, is the main body of a ship, without either masts, yards, sails, or rigging.

HUMMING-*bird*. See TROCHILUS.

HUMULUS, the *hop*, a genus of the pentandria order, in the diœcia class of plants, and in the natural method ranking under the 53d order, scabridæ. The male calyx is pentaphyllous; there is no corolla; the female calyx is monophyllous, patent obliquely, and entire; there is no corolla, but two styles, and one seed within the calyx, the latter consisting of one large leaf. There is only one species, viz. The lupulus, which is sometimes found wild in hedges near houses and gardens, but probably not indigenous. The stalk is weak and climbing; it creeps up the support in a spiral, ascending always from the right hand to the left.

Hops are said to have been first brought into England from the Netherlands in the year 1524. The richest and strongest ground is the most proper for the hop; and if it is rocky within two or three feet of the surface, the hops will prosper well; but they will by no means thrive on a stiff clay or spongy wet land. Hops require to be planted in a situation so open that the air may freely pass round and between them. The hills should be eight or nine feet asunder. Persons ought to be very curious in the choice of plants. The two best sorts are the white and the grey bind; the latter is a large square hop, more hardy, and is the more plentiful bearer, and ripens later than the former. There is another sort of the white bind, which ripens a week or ten days before the common; but this is more tender and a less plentiful bearer, but it has this advantage, that it comes first to market. If there is a sort of hop you value, and would increase plants and sets from, the superfluous binds may be laid down when the hops are tied, cutting off the tops, and burying them in the hils; or when the hops are dressed, all the cuttings may be saved, for almost every part will grow and become a good set the next spring. Five good sets should be planted in every hill, one in the middle, and the rest round about sloping. Let them be pressed close with the hand, and covered with fine earth, and the stick should be placed on each side the hill to secure it. About the middle of March they ought to be dressed in dry weather, having with an iron picker cleared away all the earth out of the hills, with a sharp knife cut off all the shoots which grow up with the binds the last year; and also all the young suckers, that none be left to sun in the alley, and weaken the hill, to cut one part of the stock lower than the other, making that part low that was left highest the preceding year In dressing hops that have been planted the year before, cut off both the dead tops and the young suckers which have sprung up from the sets, and also to cover the stocks with fine earth, a finger's length in thickness. About the middle of April the hops are to be poled. Two or three binds are enough for a pole and all the sprouts that you have no occasion for are to be plucked up. About the beginning of July the hops begin to blow, and will be ready to gather about the latter end of August. A judgment may be made of their ripeness by their strong scent, their hardness, and the brownish colour of their seed. When by these tokens they appear to be ripe, they must be picked with all the expedition possible. The best method of drying hops is with charcoal on an oast or kiln, covered with hair cloth, of the same form and fashion that is used for drying malt. It may be known when they are well dried by the brittleness of the stalks, and the easy falling off of the top leaves. As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, and then bag them; the harder they are trodden, the better they will keep.

HURDLES, in fortification, twigs of willows or osiers interwoven close together, sustained by long stakes, and usually laden with earth.

HURDLES, in husbandry, certain frames, made either of split timber, or of hazel-rods wattled together, to serve for gates in inclosures, or to make sheepfolds, &c

HURRICANE, a furious storm of wind, owing to a contrariety of winds. Hurricanes are frequent in the West Indies, where they make terrible ravages, by rooting up trees, destroying houses, shipping, and the like. The natives, it is said, can foretel hurricanes by the following prognostics: 1. All hurricanes happen either on the day of the full, change, or quarter of the moon. 2. From the unusual redness of the sun, the great stillness, and at the same time, turbulence of the skies, swelling of the sea, and the like, happening at the change of the moon, they conclude there will be a hurricane next full-moon, and if the same signs be observed on the full-moon, they may expect one next new moon. As to the cause of hurricanes, they undoubtedly arise from the violent struggle of two opposite winds. Now as the wind betwixt the tropics is generally easterly, and upon the sun's going back from the northern tropic, the western winds pour down with violence upon those parts, the opposition of these contrary winds cannot fail to produce a hurricane. Hurricanes shift not through all the points of the compass, but begin always with a north wind, veer to the east, and then cease; and their shifting between these two points is so sudden and violent, that it is impossible for any ship to veer with it; whence it happens that the sails are carried away, yards and all, and sometimes the masts themselves wreathed round like an osier.

HUSBAND and *wife*, usually called baron and feme, are one person in law: that is, the very being or legal existence of the woman is suspended during the marriage, or at least is incorporated and consolidated into that of the husband, under whose protection and cover she performs every thing. She is therefore called in our law a *feme covert*, that is, under the protection and influence of her husband, her baron, or lord; and her condition during her marriage is called her coverture.

A man cannot grant lands to his wife during her coverture, nor any estate or interest to her, nor enter into covenant with her. But he may by his deed covenant with others for her use, as for her jointure, or the like; and he may give to her by devise or will, because the devise or will does not take effect till after his death.

All deeds executed by the wife, and acts done by her during her coverture, are void, except a fine, or the like matter of record, in which case she must be solely and secretly examined, that it may be known whether or no her act is voluntary.

A wife is so much favoured in respect of that power and authority which her husband has over her, that she shall not suffer any punishment for committing a bare theft in company with, or by coercion of her husband. But if she commits a theft of her own voluntary act, or by the bare command of her husband, or is guilty of treason, murder, or robbery, in company with or by coercion of her husband, she is punishable as much is if she was sole; because of the odiousness and dangerous consequences of these crimes.

By marriage the husband has power over his wife's person; and the courts of law still permit a husband to restrain a wife of her liberty, in case of any gross misbehaviour. But if he threatens to kill her, &c. she may make him find surety of the peace, by suing a writ of supplicavit out of chancery, or by preferring articles of the peace against him in the court of king's bench, or she may apply to the spiritual court for a divorce propter sævitatem.

The husband by marriage obtains a freehold in right of his wife, if he takes a woman to wife that is seised of a freehold; and he may make a lease thereof for 21 years, or three lives, if it is made according to the statute. 32 Hen. VIII. c. 28.

The husband also gains a chattel real, as a term for years, to dispose of if he pleases by grant or lease in her life-time, or by surviving her: otherwise it remains with the wife. And upon execution for the husband's debt, the sheriff may sell the term during the life of the wife.

The husband also by the marriage has an absolute gift of all chattels personal in possession of the wife in her own right, whether he survives her or not. But if these chattels personal are choses in action, that is, things to be sued for by action, as debts by obligation, contract, or the like, the husband shall not have them, unless he and his wife recover them.

By custom in London, a wife may carry on a separate trade; and as such, is liable to the statutes of bankruptcy with respect to the goods in such separate trade, with which the husband cannot intermeddle.

If the wife is indebted before marriage, the husband is bound afterwards to pay the debt, living with the wife; for he has adopted her and her circumstances together. 1 Black. 143. But if the wife dies, the husband shall not be charged for the debt of his wife after her death, if the creditor of the wife does not get judgment during the coverture. 9 Co. 72.

The husband is bound to provide his wife necessaries; and if she contracts for them, he is obliged to pay for the same; but for any thing besides necessaries, he is not chargeable And also if a wife elopes, and lives with another man, the husband is not chargeable even for necessaries; at least if the person who furnishes them is sufficiently apprised of her elopement.

A man having issue by his wife born alive, shall be tenant by the courtesy of all the lands in fee simple, or fee tail general, of which she shall die seised.

And after her death he shall have all chattels real; as the term of the wife, or a lease for years of the wife, and all other chattels in possession; and also, all such as are of a mixed nature (partly in possession and partly in action), as rents in arrear, incurred before the marriage or after; but things merely in action as of a bond or obligation to the wife, he can only claim them as administrator to his wife, if he survive her.

If the wife survives the husband, she shall have for her dower the third part of all his freehold lands: so she shall have her term for years again, if he has not altered the property during his life: so also she shall have again all other chattels real and mixed: and so things in action, as debts shall remain to her, if they were not received during the marriage.

But if she elopes from her husband, and goes away with her adulterer, she shall lose her dower, unless her husband had willingly, without coercion ecclesiastical, been reconciled to her, and permitted her to cohabit with him.

HUSBANDRY. See AGRICULTURE.

HYACINTH, in natural history, a genus of pellucid gems, whose colour is red with an admixture of yellow.

HYACINTHUS, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is campanulated, and there are three melliferous pores at the top of the germen. There are 17 species, of which the most remarkable is the orientalis, or eastern hyacinth. Of this there are a great number of varieties, amounting to some hundreds, each of which differs from the rest in some respect or other. These plants are cultivated with the greatest success in Holland, whence great numbers are annually imported into Britain.

HYALITE. Colours yellowish and greyish-white. Generally small reniform, botroidal, or stalactitic. Lustre splendent. Fracture small conchoidal. Translucent. Moderately hard. Sp. gr. 2.2. Infusible before the blowpipe. Its constituents are, 92 silica, 6.33 water. It has been hitherto found principally near Frankfort on the Maine, where it occurs in fissures in vesicular basalt and basaltic greenstone.

HYBERNACULUM, in botany, that part of the plant which defends the embryo-herb from injuries during the severities of winter, hence the name, hybernaculum or winter quarters.

HYBLÆA. See PHALÆNA.

HYDRA, in astronomy, a southern constellation imagined to represent a water-serpent. The number of stars in this constellation in Ptolemy's catalogue is 25, and in the Britannic catalogue 68.

HYDRA, a genus of vermes zoophyta. The generic character is, animal fixing itself by the base, linear, gelatinous naked contractile, and

furnished with setaceous tentacula, inhabiting fresh water, and producing its deciduous offspring, or eggs, from the sides. The hydra-viridis inhabits the stagnant waters and slowly-running streams of Europe, generally on the surface of plants, and appears like a little transparent green jelly, when contracted and transparent: when expanded it is a linear body, fixed at one end, and surrounded at the other by tentacula, or arms placed in a circle round the mouth, and gradually producing its young from the sides, which at first seem small papillæ, increasing in length, till they assume the form of the parent, and then dropping off. Like all its tribe, it has the power of reproducing parts, which have been destroyed, and if cut or divided in any direction, each separate part becomes a perfect polype. See Adams on the Microscope. There are five species.

HYDRARGYRUM, a name given in the Pharmacopeia to mercury or quicksilver.

HYDRANGEA, a genus of the digynia order, in the decandria class of plants, and in the natural method ranking under the 13th order, succulentæ. The capsule is bilocular, birostrated, and cut round, or parting horizontally. There are three species, of which the hortensis is a very handsome, and now a popular greenhouse plant.

HYDRATES. Compounds, in definite proportions, of metallic oxides with water.

HYDRAULICS. This branch of science embraces the phenomena exhibited by water issuing from orifices in reservoirs, projected obliquely or perpendicularly in jets-d'eaux, moving in pipes, canals, and rivers, oscilating in waves, or opposing a resistance to solid bodies.

GENERAL PRINCIPLES.

When water flows from a vessel which has a hole or aperture in the bottom, small in comparison to the width of the vessel, the water descends vertically, and the surface appears smooth, but at three or four inches from the bottom the particles turn from this direction, and proceed on all sides with a motion more or less oblique towards the aperture. The same effect takes place when water flows through an aperture laterally. The tendency of the particles towards the aperture is a necessary consequence of their perfect mobility; for they will certainly be directed towards the point where there is the least resistance, and that point is the aperture.

It is also to be observed, that in this case, at a small distance from the bottom, a kind of funnel is formed in the water, the point of which corresponds to the centre of the aperture; when, however, the water flows through a lateral orifice or aperture, there is formed only a kind of half funnel, which does not appear to commence till the surface is near touching the upper side of the hole. It is probable that the funnel begins to form itself from the first moment of the flow; but it does not become perceptible till the surface is only at a small distance from the bottom. It appears also, that the funnel commences higher or lower, according to the width of the bottom; and that the formation of it is less prompt or less perceptible, according to the proportion of the aperture to the extent of the bottom. The funnel is also augmented by any roughness which may exist at the sides or bottom of the vessel.

Water flows out of a small hole in the bottom of a vessel with a velocity equal to that which a ponderous body acquires in falling from a height equal to the vertical height of the surface of the fluid above the aperture.

The same law takes place in a lateral orifice; for the pressure of the fluid is equal (at the same depth) in all directions, and consequently produces the same degree of velocity.

A fluid in running out of an aperture, acquires a velocity sufficient to make it remount to a vertical height equal to that of the fluid above the aperture, in the same manner as a falling body acquires a velocity capable of making it ascend to the height from which it descended.

It is evident, from the theory of falling bodies, that if the velocity of the fluid in running through the aperture was uniformly continued, the fluid would move through a space double the height of the fluid above the aperture, in the same time that a falling body would employ in descending from that height.

The height being the same, the velocity of the fluid in running out of the orifice will always be the same, whatever the species of the fluid may be, and whatever its density. It is true, that when the fluid has more density, it presses more forcibly, but then the mass is more considerable; and it is evident, that when the moving powers are proportioned to the masses which they put in motion, the velocities are equal.

The quantities of a fluid discharged in the same space of time through different orifices, supposing the vessels equally full during the whole of the experiment, are to each other as the products of the areas of the apertures by the square roots of the heights.

It is found by experiment, that a circular orifice of an inch diameter, made in a thin vessel or partition, and under a surface of fluid four feet in height, will furnish, in one minute of time, 5436 cubic inches French.

If, therefore, it were an object to ascertain how much a circular orifice of two inches diameter, under nine feet of height from the surface of the water, would furnish in the same, the following proportion must be employed, (it must be observed, that the orifice of two inches is four times as great as an orifice of one inch, because the areas of circles are as the squares of their diameters:)

$$1 \times \sqrt{4} : 4 \times \sqrt{9} :: 5436 : x$$

Or at length

$$2 : 12 :: 5436 : 32616$$

$$\begin{array}{r} 12 \\ \hline 2)653232 \\ \hline \end{array}$$

The reader ought here to be reminded that in every branch of hydraulics the deductions of theory are extremely uncertain, and, indeed, of but little use in any of the important purposes to which this science is applicable, the general laws deduced from experiment can alone be safely employed.

The motion of fluids, and the friction and other causes by which they are impeded, form together one of the most elaborate and abstruse branches of mathematical philosophy, and would, we fear, prove very uninteresting to the generality of our readers.

The following rule, as stated by Professor

Millington, will be found sufficiently correct for most practical purposes, and its extreme simplicity not a little enhances its value

It may be practically assumed that water may flow through straight pipes of from 2 to 7 inches diameter, when lying horizontally, at the rate of 3 feet in a second, without much loss of power from friction, unless the length of the pipes be very considerable, and consequently to calculate the quantity of water that a pipe will deliver in a given time, it is only necessary to calculate the solid contents of a yard of any pipe in cubic inches, or any other measure of capacity, and to multiply this by the number of seconds contained in the given time, in order to obtain the delivery. Now, if the diameter in inches of any pipe be squared, and the right-hand figure of its square number be cut off by a decimal point, such square number will be the contents of a yard of such pipe in ale gallons and tenths. Thus, if a pipe is 6 inches in diameter, its square will be 36, which being divided as above makes 3.6, and shews that one yard of such pipe contains 3 gallons and 6 tenths. If the pipe were but two inches diameter, then its square 4 consists but of one figure, and must be considered as a decimal, thus .4 indicates that the contents of a yard of such pipe contains 0.4 four tenths of 1 gallon.

The nature of the motion, lateral pressure, gravity and momentum of fluids being investigated by the mathematical principles of hydraulics and hydrostatics, the construction of mechanical engines, for raising or moving water, and for procuring disposable power from its agency, follow as natural consequences.

In the formation of these, Mr. Millington observes, it must be kept in mind that water has a constant tendency to descend, which affords the principal resistance to be overcome in the one case, and the source of power in the other; and as water can never rise above its ordinary level, except by some extraneous force, so likewise in descending it can never produce a power equal to the elevation of more than its own quantity to a height equal to that from whence it flowed, since that would be contrary to the laws of hydrostatic equilibrium.

We shall now proceed to describe a few of the most useful and simple hydraulic machines.

Of the syphon.

A syphon is a bent tube, ABC, (Plate XXIII. fig. 1.) made of glass, metal, &c. One branch of which AB, is shorter than the other BC. In order to make use of this instrument, place the extremity of the short branch in the vessel A, which may be supposed to contain any fluid matter, as water for instance. If the air then is drawn out of the syphon (fig. 2.) by means of the long branch *x*, the liquor will begin to flow, and will not cease while the short branch AB remains immersed in the fluid. It is easy to see that the pressure of the air upon the surface of the fluid in the vessel, is the cause of its discharge through the siphon. For suppose GF the confines of the atmosphere, all the points of the surface A of the liquor will be equally pressed by the column of air AF; if, therefore, at some point of this surface, the pressure is suspended, the liquor must flow at that point, because it finds less resistance there than in any other part; this is therefore the obvious reason why the syphon becomes full immediately after the air is drawn out at the extremity C.

If the two branches of the syphon were of equal lengths, as BA, BD, the flow through the bent tube would not take place; because the column of air DG which would resist in D, being of an equal height with that which presses at A, would also be in equilibrium with it, in the same manner as the two columns of the fluid BA, BD. But since BC, one of the legs, is longer than the other, though the column of the air GC, which answers to it, is really longer than that which presses in A; yet it is not capable of preventing the passage of the fluid. To understand this more perfectly, let us consider the column of air GC to be divided into two parts, one of which GD, would form an equipoise with the column of air FA, and would be capable of stopping the flow from the tube if the branch BC ended in D. The portion of fluid which fills the part DC of the siphon, will find no other resistance in C than one coloumn of air DC of the same length with it, which is evidently very inferior to it in weight. This portion of fluid then flows out, because it greatly exceeds in weight the column of air which is opposed to it. But while it continues to flow, nothing sustains that which is above it, which flows necessarily, while the pressure of the air at A furnishes a new supply of fluid to replace that which runs out. It is by these means, that the water in the syphon continues to flow without intermission; because the resistance of the air in C is as much exceeded, as the length of the branch BC of the syphon exceeds that of the branch AB. In order to prove this, suppose there is added at C a tube to lengthen that branch, then it will plainly appear that in a given time more water will flow than would have been discharged without that augmentation to the branch BC.

Since it is the pressure of the air which elevates the fluid in the short branch BA, it follows, that the height of this branch is limited to thirty-two feet when the fluid is water, because the pressure of the atmosphere cannot elevate water higher; but when the liquor is mercury, the height of the short branch should not exceed thirty inches, because the atmosphere cannot sustain mercury at a greater height.

A syphon may be disguised in a cup, (fig. 3.) from which no liquor will flow, until it be raised above the bend of the syphon; but when the efflux once begins, it will continue to flow till the vessel be emptied. This has been called Tantalus's cup, because it is usual to place a hollow figure over the inner tube of such a length, that when the fluid has got nearly up to the lips of the figure, the syphon may begin to act and empty the cup.

Intermitting springs, which puzzled philosophers formerly, are found to be natural syphons, which may be thus explained: Let A (fig. 4.) be part of a hill, within which there is a cavity BB, and from this cavity, a vein or channel running in the direction BCD. The rain that falls upon the side of the hill will sink and strain through the small pores and crevices in the hill, and fill the cavity BB with water. When the water rises to the level of C, the vein BCD will be full, and the water will run through it as a syphon, and will empty the

cavity BB. It must then stop, and when the cavity is again filled, it will begin to run again.

The principal use to which the syphon is applied, is that of drawing off liquors from one vessel to another, as represented in fig. 5.

Of the Pump.

There are two sorts of pumps, which essentially differ; and all the varieties are but modifications of these. One has a piston with a perforation and valve; the other has a solid piston; to the former is given the name of the common sucking-pump; the latter is denominated the forcing-pump.

Fig. 6 represents the common sucking-pump. AA is a cylinder of cast iron, bored smooth withinside; it has a flanch at the top, by which it is screwed to the wooden cistern B, which conveys the water away from the pump. It has also a flanch D at its lower end, to screw on the pipe E, which brings the water to the pump. In the same flanch is a pair of valves, *aa;* and the bucket or piston F, which slides within the barrel, has another similar pair of valves in it. This bucket is screwed to an iron rod G, which is moved up and down by some machine. When the bucket F descends, its valves *bb* open as in the figure, and allow the water which fills the barrel to pass through them. When the bucket arrives at the bottom of the barrel, it is drawn up again; and as the valves shut, and prevent the water from returning through the bucket, it lifts all the water contained in the barrel into the cistern B. At the same time the bucket, in rising, makes a vacuum beneath it: the pressure of the atmosphere upon the surface of the water in the well, causes it to mount up through the pipe E, open the valves *aa*, and fill the barrel AA. When the bucket begins to descend, the column of water beneath it descends also, till it is stopped by the shutting of the valves *aa*; the valves *bb* then open, and allow the water to pass through as before.

Fig. 7 is a forcing-pump. In this the barrel AA is screwed upon a square box BB, which has a pair of valves *aa* at the top of the pipe C, bringing water from the well; and another similar pair at the other end of the pipe D, which is likewise screwed to the square box. The plunger E is solid: when it is drawn up it makes a vacuum in the barrel, and draws the water up through the valves *aa* from the well to fill the barrel. The plunger is then forced down, the valves *aa* shut, and as the water has no other way out of the box, it passes through *bb* up the pipe D. The plunger is then drawn up, the valves *bb* shu,t and *aa* open to supply the barrel as before.

Fig. 8 is a lift-pump. The barrel AA is screwed by its top to a shorter barrel H, from which the crooked pipe B proceeds. A cover *h* is screwed over the top of the barrel H, with a stuffing-box in the middle of it; which is a box containing cotton, or other light substances, through which the piston-rod E passes. The piston F has two valves *bb* in it, similar to fig. 1; and at the bottom of the barrel are two valves similar to *aa* (fig. 6.) When the piston descends, the lower valves prevent the water from going out of the barrel: and the valves *bb* open, to let the water pass through them. When the piston returns, the valves in it shut, and it raises the water through the pipe B, the stuffing-box preventing its getting out at the top of the barrel, by the side of the piston-rod, as in fig. 1; and at the same time, by making a vacuum beneath it, filling the barrel through the lower valves in the same manner as the sucking-pump. The piston then descends, the lower valves shut, and *bb* open as before. In all the figures, W represents a hole in the bottom of the pump, to get at the valves to repair them, and when the pump is at work, a cover is screwed over it, as shewn in fig. 3. Pumps constructed as in the drawings are seldom less than one or two feet in the bore of the barrel.

That eminently useful engine termed the *fire-engine*, or more properly, the fire extinguishing engine, is nothing more than two forcing pumps so combined, that their joint action produces a constant and powerful stream of water, which may be directed at pleasure towards the point at which it is wanted.

The most approved construction of the fire-engine is, we believe, that of the ingenious Mr. Rowntree. It consists of a double force pump of a peculiar construction, similar in its action to the well known beer engine, by the same inventor.

From the following short description of the section of this engine, exhibited in fig. 9 the reader will be enabled to comprehend the nature of its action. AAAA is a cast-iron cylinder truly bored, being 10 inches in diameter, and 15 inches long. At each end there is a flanch, on which are screwed two covers with stuffing-boxes, *aa* in their centres, through which the spindle BB of the engine passes: the piston D is affixed to the spindle within the cylinder, and fits it tight all round by means of leathers. At E, a partition called a saddle is fixed in the cylinder, and fits on the back of the spindle tight by a leather. The cylinder is thus divided by the saddle E and the piston D into two parts, the capacity of which can be increased or diminished by moving the piston, with proper passages and valves to bring in and carry away the water; this forms a pump. These passages are cast in one piece with the cylinder; and *d*, for admitting the water is square, and extends about one-third round the cylinder; it is connected at bottom with the pipe *e*; at its two upper ends, it opens into two large chambers, *f g*, which extend nearly the whole length of the cylinder, and are closed by covers, *h*, *h*; *i*, *k*, are square openings in the cylinder communicating with the chambers, *f*, *g*; *l*, *m*, are two valves, closing their respective ends of the curved passage *d*; *n*, *o*, are two passages from the top of the cylinder, to convey away the water; they come out in the top of the cylinder, which, together with the top of the chambers *f*, *g*, form a flat surface, and are covered with two valves, *p*, *q*, to retain the water which has passed through them. A chamber, K, is screwed over these valves and has the air vessel *k*, as seen in the elevation of the engine fig. 10, screwed into its top. From each side of this chamber, a pipe, *w*, *w*, proceeds, to which a leathern hose is screwed to conduct the water to the directing pipe. Levers marked *x x*, are fixed to the spindle at each end, and carry the handles H, H, by which men work the engine. When the piston moves, as shewn by the arrow, it produces a vacuum in the chamber *f*, and in that part of the cylinder contiguous to it; the water in the pipe *e*, then opens the valve *m*, and fills the cylinder.

The same motion forces the water in the other part of the cylinder through the valve *g*, into the chamber K, and thence to those through the pipe *w*; the piston being turned the other way, reverses the operation with respect to the valve, though it continues the same in itself.

The chambers, *f*, *g*, being so large, allow sufficient room to lodge a greater quantity of dirt than is likely to be accumulated in the use of the engine at any one fire, and if any of it accidentally falls into the cylinder, it is gently lifted out again into the chambers by the piston, without being any obstruction to its motion; to clear the engine from the dirt, two circular plates, *r*, *r*, five inches diameter, are unscrewed from the lids, *h*, *h*, of the chambers, *f*, *g*, and when cleaned are screwed on again: these screw covers fit perfectly tight without leather, and can be taken out, the engine cleared, and enclosed again in a very short time. Besides the engines described above, we might enumerate many others, such as the spiral-pump of Archimedes; the tympanum of Vetruvius; the Persian wheel; the hydraulic ram of Montgolfier; the chain-pump and hair-rope machine; Whitehurst's engine; the Hungarian machine, &c.; but to describe these would swell this article far beyond its proper limits. The hydraulic press will be found shortly described, under the article HYDROSTATICS, which see.

HYDRAULICON, *water organ*, in music, an instrument acted upon by water, the invention of which is said to be of higher antiquity than that of the wind organ.

HYDROCELE, in surgery, denotes any hernia arising from water, but is particularly used for such a one of the scrotum, which sometimes grows to the size of one's head, without pain, but very troublesome to the patient.

HYDROCEPHALUS, in surgery, a preternatural distention of the head to an uncommon size, by a stagnation and extravasation of the lymph, which when collected within side of the bones of the cranium, the hydrocephalus is then termed internal; as it is external, when retained between the common integuments and the cranium.

HYDROCHARIS, the *little water-lily*, a genus of the enneandria order, in the diœcia class of plants, and in the natural method ranking under the first order, palmæ. There is only one species, a native of Britain, growing in slow streams and wet ditches. There is a variety with double flowers, of a very sweet smell.

HYDROGEN GAS. The lightest species of ponderable matter hitherto known. It was discovered by Mr. Cavendish in 1766. It can be procured only from water, of which it forms an essential constituent.

This gas is colourless, and possessed of all the physical properties of air. It has usually a slight garlic odour, arising probably from arsenical particles derived from the zinc. When water is transmitted over pure iron in a state of ignition, it yields hydrogen free from smell. It is eminently combustible, and, if pure, burns with a yellowish-white flame; but, from accidental contamination, its flame has frequently a reddish tinge. If a narrow jar filled with hydrogen be lifted perpendicularly, with the bottom upwards, and a lighted taper be suddenly introduced, the taper will be extinguished, but the gas will burn at the surface, in contact with the air. Animal life is speedily extinguished by the respiration of this gas, though Sir H. Davy has shewn, that if the lungs be not previously exhausted by a forced expiration, it may be breathed for a few seconds without much seeming inconvenience.

If a bottle containing the effervescing mixture of iron and dilute sulphuric acid, be shut with a cork, having a straight tube of narrow bore fixed upright in it, then the hydrogen will issue in a jet, which being kindled, forms the philosophical candle of Dr. Priestley. If a long glass tube be held over the flame, moisture will speedily bedew its sides, and harmonic tones will soon begin to sound. Mr. Faraday, in an ingenious paper inserted in the 10th number of the Journal of Science, states, that carbonic oxide produces by the action of its flame, similar sounds, and that therefore the effect is not due to the affections of aqueous vapour, as had formerly been supposed. He shews, that the sound is nothing more than the report of a continued explosion, agreeably to Sir H. Davy's theory of the constitution of flame. Vapour of ether, made to burn from a small aperture, produces the same sonorous effect as the jet of hydrogen, of coal gas, or olefiant gas, on glass and other tubes. See CHEMISTRY.

HYDROMETER. The names *aereometer*, *hydrometer*, *gravimeter*, have been indiscriminately applied to those instruments which are employed for determining the specific gravities of spirituous liquors and other fluids.

The best method of weighing equal quantities of corrosive volatile fluids, to determine their specific gravities, appears to consist in enclosing them in a bottle with a conical stopper, in the side of which stopper a fine mark is cut with a file. The fluid being poured into the bottle, it is easy to put in the stopper, because the redundant fluid escapes through the notch, or mark, and may be carefully wiped off. Equal bulks of water, and other fluids, are by this means weighed to a greater degree of accuracy, care being taken to keep the temperature as equal as possible, by avoiding any contact of the bottle with the hand or otherwise. The bottle itself shews with much precision, by a rise or fall of the liquid in the notch of the stopper, whether any such change have taken place.

The hydrometer of Fahrenheit consists of a hollow ball, with a counterpoise below, and a very slender stem above, terminating in a small dish. The middle, or half length of the stem, is distinguished by a fine line across. In this instrument every division of the stem is rejected, and it is immersed in all experiments to the middle of the stem, by placing proper weights in the little dish above. Then, as the part immersed is constantly of the same magnitude, and the whole weight of the hydrometer is known, this last weight added to the weights in the dish, will be equal to the weight of fluid displaced by the instrument, as all writers on hydrostatics prove. And accordingly, the sp. gravities for the common form of the tables will be had by the proportion:

As the whole weight of the hydrometer and its
load, when adjusted in distilled water.
Is to the number 1000, &c.
So is the whole weight when adjusted in any
other fluid.
To the number expresing its specific gravity

There are various kinds of hydrometers in

use, but that of Sikes appears to be the most generally approved, since it is universally used in the collection of the revenue in both kingdoms.

HYDROPHILUS, in natural history, a genus of insects of the order coleoptera, antennæ clavate, the club perfoliate; feelers four, filiform; the hind legs are formed for swimming, fringed on the inner side, and nearly unarmed with claws. The insects of this genus,) like those of the DYTISCUS, which see,) are inhabitants of ponds and stagnant waters, where they swim with much dexterity, turning round with great velocity; they fly abroad by night in search of other waters. The males are distinguished from the females, by having a horny concave flap or shield on the fore legs, near the setting on of the feet; the hind legs are peculiarly fitted for their aquatic situation, being furnished on the inner side with a series of long and close-set filaments, resembling a fin, by which they are enabled to swim with great ease.

HYDROPHOBIA, from ὑδωρ, *water*, and φοβεω, *to fear*, a dread of water; a symptom of the disease caused by the bite of a mad dog.

Both the cause and the cure of this terrible disorder seem as yet involved in impenetrable obscurity.

HYDROSCOPE, an instrument anciently used for the measuring of time. The hydroscope was a kind of a water-clock, consisting of a cylindrical tube, conical at bottom: the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out, the vertex of the cone pointed out the hour.

HYDROSTATICAL *balance*, a kind of balance contrived for the easy and exact finding the specific gravities of bodies, both liquid and solid. See HYDROSTATICS.

HYDROSTATICS. The science of hydrostatics, has for its object the examination of the mechanical laws which regulate the motions, pressure, gravitation, and equilibrium of inelastic fluids, and also their effect on those bodies which float upon, or are immersed in them.

Archimedes, among the ancients, accomplished the most remarkable discoveries in this science. He is honoured even at this day, as the inventor of the ingenious hydrostatic process, by which the purity or baseness of a crown of gold was ascertained. Among the moderns we are indebted to Gallileo, Torricelli, Descartes, Pascal, Guglielmini, and Mariotte, for the best information on this subject; and by their experiments (which are as curious as they are decisive) we are instructed in what we may expect or fear from the power of fluids violently acted upon by the principle of gravity, and in what manner, and upon what principles we may employ, for the use of man, the hydraulic machines.

The propensity which bodies have of approaching towards the earth, is the only cause of what we term weight or gravity, and it is by the continual efforts which they make to obey that law, that they press upon every obstacle which impedes their progress. As fluids, like solid bodies, are impelled by their gravity, so in this case they press upon every object which opposes their fall; but from their nature they press in a different manner from solid bodies.

Fluids are substances, the component parts of which are moveable among themselves, having scarcely any cohesion one with another, and moving independently of each other. The proper objects of the hydrostatic science are those fluids which, in common language, are termed liquids, or those which always present to us a plain surface, level or parallel to the horizon.

All liquid substances are not equally so. Water and oil both flow when the vessels, which contain them, are either overturned or broken; but the effusion of oil is slower than that of water, because the particles of oil have more cohesion among themselves. The most singular effects in hydrostatics principally depend, perhaps, upon the extreme minuteness of the particles of fluids, but at least upon their great mobility.

To preserve order in the consideration of this subject, it will be necessary to divide the objects of our inquiry into three branches. In the first place, we shall consider in what manner the principle of gravity acts on the particles of fluids, and the phenomena which it produces in the fluids themselves; as well as their action against the sides, the bottoms, and tops of the vessels in which they are contained. Secondly, in what manner fluids of different densities act upon each other; and thirdly, the action of fluids on bodies immersed in them.

I. In pursuing the first object of this inquiry, it may be established as an axiom:

1. That the parts of the same fluid act, with respect to their weight or pressure, independently of each other.

This property arises from their having scarcely any cohesion among themselves. It is otherwise with solid bodies; their several parts adhering together, they press in one common mass; hence the falling of solid bodies is productive of a different effect from that of liquids. We dread the falling of a pound of ice upon our heads, while we are much more indifferent concerning that of a pound of water. The latter, in its descent, is divided by the resistance of the air, by which some of its parts are retarded more than others: and by being thus divided it requires a larger surface, which abates its effect. On the contrary, a solid body falls upon a small space, which receives its whole force.

It follows from this principle, that if an aperture is made at the bottom of a vessel full of any fluid, in order to prevent the flowing out of the liquor, it is only necessary to counteract the weight of that column of fluid which has the aperture for its base, and that to counteract that weight it is the same whether the vessel is full of liquor, or whether it contains only a column, the base of which shall be equal to the aperture at the bottom.

Let the cylindrical vessel of glass A B, (Plate XXIV. fig. 1,) have a hole in the bottom at C, furnished with a cylindrical ferule of copper of an inch diameter D, which is to be stopped with a piston G, well fitted to the ferule, and oiled, that it may yield to a moderate pressure. Let the piston be supported by a small rod G H, fastened at H to the silk which unites with the portion of the pulley M. with which the extremity of the lever M N is furnished,

and which has for its centre of motion the point L. The other portion of the pulley N, which terminates the other extremity of the lever, is also furnished with lines of silk, which support the small bason or scale I. Upon the copper ferule D, fit a cylindrical tube of glass FE, the interior diameter of which is equal to that of the ferule, and its height equal to that of the vessel AB. When the apparatus is disposed in this manner, fill the tube EF with water, and continue to put small weights into the scale I, until the piston begins to rise. Afterwards take away the glass tube EF, and place the piston G in the copper ferule O, and pour water into the large vessel AB, and it will appear that the same weights as before in the bason I, will raise up the piston when the large vessel AB is entirely full. Hence it follows that there is the same power to be counteracted, whether there rests upon the piston only a column of water of its own size, or whether the vessel AB is entirely full. Such a column, therefore, presses upon its base, independently of the rest of the water contained in the vessel.

To account for this, let us suppose all the water in a vessel to be divided into several columns, 1, 2, 3, 4, 5, (fig. 2,) each composed of an equal number of parts. If the bottom of the vessel is opened in *a*, the column 3, being no longer supported, will descend through the aperture, sliding between the two columns 2 and 4, which are supported by the parts of the bottom of the vessel *b* and *c*, all the moveable parts of which become, so to speak, small rollers, which retard the fall only in a very slight degree. This effect is the result of the small degree of cohesion between the parts of the fluid. If the columns 1 and 2 on the one part, and 4 and 5 on the other, were composed of parts adhering together, they would retard each other in their descent during their whole length; and by the fall of the column 3, a void would be made between them. But as all the particles are extremely minute, moving easily upon each other, they descend when the summit of the column 3 begins to descend having no longer any support from that side: and the superfices of the whole mass descends in the same manner.

2. Fluids press equally in all directions. In other words, they not only press from the top to the bottom, like other bodies, but they also press according to their weight, upon all bodies that oppose them in a lateral direction, and even from the bottom to the top. Hence, if a cask is filled with liquid oil, the oil will run out if an aperture is made in the side, but when it is congealed it will not run out on account of its having become a solid body, for solid bodies press only from their vertex to their base, and not laterally.

To understand this lateral pressure of fluids, and also that which they exert from their base towards their vertex, it is necessary to consider them as a mass of small globules deposited in a vessel: and to remember that these minute globules are not arranged regularly as upon a cord, but that very frequently one column exercises its pressure between two others, and has a propensity to displace them, as may be seen in fig. 3, where the perpendicular pressure, which is made opposite to the point *d*, is directed by the lateral columns towards the sides *e*, *f* of the vessel, in such a manner, that if the vessel was open in those places the liquid would flow out, on account of the great mobility of its parts. It is by the same mode of reasoning that the pressure of fluids, from their base towards their vertex, is accounted for.

3. All the parts of the same fluid are in equilibrium with each other, whether they are contained in one vessel or many, provided they communicate with each other; and their surfaces also are always in a plane parallel to the horizon.

This is a consequence of the principle which has been before established; for, since the particle *k*, fig. 3, would be raised from the base towards the top, unless a column equal to the column *i k* pressed upon it to retain it in its place; it follows, that to be in equilibrium, the upper extremities of the two columns should be in the same horizontal plane, or in points equally distant from the centre of the earth; which points, however, cannot be found by a right line; for in the distance of a thousand fathoms there is about one foot difference in the perpendicular height. It follows from the equal pressure of fluids in all directions, that the horizontal bottom of a vessel sustains just the pressure of a column of the fluid, whose base is the area of the bottom of the vessel, and whose perpendicular height is equal to the depth of the fluid. Thus in the vessel ABC, fig. 4, the bottom BC does not sustain a pressure equal to the whole quantity of fluid contained in the vessel, but only of a column whose base is CB, and height CE. Also in the vessel FGH, the bottom GH, fig. 5, sustains a pressure equal to what it would be if the vessel were as wide at the top as at the bottom.

This leads us to notice what is called the hydrostatical paradox, which is thus expressed, "that a quantity of fluid, however small, may be made to counterpoise a quantity however large." Thus, if to the wide vessel AB, fig. 6, the tube CD is attached, communicating with AB, and then water be poured into either of them, it will stand at the same height in both, consequently there is an equilibrium between them. It may thus be illustrated: Let ABDG, *fig.* 7, represent any cylindrical vessel, to the inside of which is fitted a cover C, which will slide up and down without suffering any water to pass between the edges. In the cover is inserted a small tube, CF, which is open at top, and communicates with the inside of the cylinder beneath the cover at C. The cylinder is filled with water, and the cover put on. Then if the cover is loaded with a weight, as a pound, it will be depressed, and the water rise in the tube to E, and the weight will be sustained. If another weight be added, the water, will rise to F, and the weight sustained, and so on, according to the weight added, and the length of the tube. Now the weight of the water in the tube is but a few grains, yet its lateral pressure serves to sustain as much as the weight of a column of water whose base is equal to that in the tube. Thus the column E d produces a pressure in the water contained in the cylinder, equal to what would have been produced by the column A a D d; and as this pressure is exerted equally every way, the cover will be pressed upwards with a force equal to the weight of A a d D; consequently if A a d D weigh a

pound, EC will sustain a pound: and the like of any other heights and weights.

The instrument commonly employed to shew that a small quantity of water is capable of exerting great pressure, is called the hydrostatic bellows. The use of this machine is now nearly laid aside; and an excellent substitute for it is found in the simple invention of the ingenious Ferguson, of which the following is his own description.

In fig. 8, ABCD is an oblong square box, in one end of which is a round groove, as at *a*, from top to bottom, for receiving the upright glass tube I, which is bent to a right angle at the lower end, as at *i* in fig. 9, and to that part is tied the neck of a large bladder K, which lies in the bottom of the box. Over this bladder is laid the moveable board L, fig. 10, in which is fixed an upright wire M; and leaden weights NN, to the amount of sixteen pounds, with holes in their middle, which are put upon the wire, over the board, and press upon it with all their force. The cross bar *p* is then put on, to secure the tube from falling, and keep it in an upright position; and then the piece EFG is to be put on, the part G sliding tight into the dove-tailed groove H, to keep the weights NN horizontal, and the wire M upright; there being a round hole *e* in the part EF for receiving the wire. There are four upright pins in the four corners of the box within, each almost an inch long, for the board L to rest upon: to keep it from pressing the sides of the bladder below it close together at first.

The whole machine being thus put together, pour water into the tube at top; and the water will run down the tube into the bladder below the board; and after the bladder has been filled up to the board, continue pouring water into the tube, and the upward pressure which it will excite in the bladder, will raise the board with all the weight upon it, even though the bore of the tube should be so small, that less than an ounce of water would fill it.

Although this principle of the upward pressure of water was known to the ancients, it was never applied to any useful purpose till the late Mr. Joseph Bramah constructed on it the well-known *hydraulic press*, which is now so extensively used where great pressure is required. Of this amazingly powerful machine, we shall here give a brief description. Fig. 11 is a section of one of one of these presses, in which *t* is the piston of the large cylinder, formed of a solid piece of metal, turned truly cylindrical, and carrying the lower board *v* of the press upon it; *u* is the piston of the small forcing pump, being also a solid piece of metal of a cylindrical form, and moved up and down by the handle *w*; the whole lower part of the press is sometimes placed in a case *x x*, containing more than sufficient water, as at *y*, to fill both the cylinders, and the suction pipe of the forcing pump *u*, dipping into this water will be constantly supplied. When the handle *w* moved upwards, the water will rise through conical metal valve *z*, opening upwards into the bottom of the pump *u*, and when the handle is depressed, that water will be forced through another similar valve *a*, opening in an opposite direction in the pipe of communication between the pump and the great cylinder *b*, which will now receive the water, by which the piston rod *t* will be elevated at each stroke of the pump. Another small conical valve *c*, is applied by means of a screw to an orifice in the lower part of the large cylinder, the use of which is to release the pressure whenever it may be necessary, for on opening this valve, any water which was previously contained in the large cylinder *b*, will run off into the reservoir *y*, by the passage *d*, and the piston *t*, will descend, so that the same water may be used repeatedly.

This machine not only acts as a press, but is capable of many other useful applications, such as a jack for raising heavy loads, or even buildings;—to the purpose of drawing up trees by their roots, or the piles used in building.

Upon the principle of the upward pressure of fluids, a piece of lead may be made to swim in water, by immersing it to a proper depth, and keeping the water from getting above it. Let CD, fig. 12, be a glass tube open throughout, and G a flat piece of lead half an inch thick, fitted exactly to the lower end of the tube, but not to go within it. By means of the packthread L, the lead is held close to the bottom of the tube, and in this situation it is immersed in the water of the vessel K to somewhat more than eleven times its own thickness, because lead is more than eleven times heavier than water; then the thread L may be let go, but the lead will not fall, but be sustained by the upward pressure of the water below it. If some water be poured upon the lead, or if the tube be raised a little, the lead will fall by its own weight, which will then be too heavy for the pressure of the water round the tube, upon the column of water below it.

II. The effects of gravity on fluids of different densities, will, from what has preceded, not be very difficult to comprehend.

If two fluids of different densities are placed in a state of equipoise with each other, and have the same base, their perpendicular heights above the horizon will be in a reciprocal ratio to their densities or specific gravities.

If, for example, mercury is put into an inverted syphon, and water is poured into one of the branches. in order to elevate the mercury in the other branch one inch above its level, it is necessary that the water should be about thirteen inches and a half high. The height of the water then will be thirteen times and a half that of the mercury; because the specific gravity of mercury is about thirteen times and a half as great as that of water.

III. The action of fluids on solid bodies immersed in them forms the doctrine of specific gravity.

When a solid body is plunged into a fluid, it occupies a space in that fluid exactly equal to its own magnitude. The quantity of fluid then so displaced, either equals in density, and consequently in weight, the solid which displaced it; or, on the contrary, one of the two must weigh more than the other. In the last case which is most common, the quantity by which the heavier body surpasses the lighter, is called the specific weight or gravity.

If a body is heavier than the fluid in which it is immersed, it is evident that it will sink to the bottom by its specific gravity. If a body is lighter than the same bulk of the fluid into which it is plunged, a part of it will swim, and the remaining part which is immersed displaces a quantity of fluid, which weighs exactly as much as the whole of the solid body

The instrument used for finding the specific gravities of bodies, is called the hydrostatic balance, fig. 13.

It differs very little from a common balance that is nicely made; only it has a hook at the bottom of one of the scales, on which different substances that are to be examined may be hung by horse-hairs, so as to be immersed in a vessel of water, without wetting the scale.

If a body thus suspended under the scale, at one end of the balance, be first counterpoised in air by weights in the opposite scale, and then immersed in water, the equilibrium will be immediately destroyed; then, if as much weight be put into the scale from which the body hangs, as will restore the equilibrium, without altering the weights in the opposite scale; that weight which restores the equilibrium, will be equal to the weight of a quantity of water as large as the immersed body; and if the weight of the body in air be divided by what it loses in water, the quotient will shew how much that body is heavier than its bulk of water. Thus, if a guinea suspended in air, be counterbalanced by 129 grains in the opposite scale of the balance, and then, on its being immersed in water, it becomes so much lighter as to require 7¼ grains put into the scale over it, to restore the equilibrium, it shews that a quantity of water of equal bulk with the guinea, weighs 7¼ grains, or 7.25; by which divide 129 (the weight of the guinea in air,) and the quotient will be 17.793; which shews that the guinea is 17.793 times as heavy as its bulk of water. And thus, any piece of gold may be tried, by weighing it first in air, and then in water; and if upon dividing the weight in air by the loss in water, the quotient comes out to be 17.793, the gold is good: if the quotient be 18, or between 18 and 19, the gold is very fine; but if it be less than 17, the gold is too much alloyed with other metal. By this method, the specific gravities of all bodies that will sink in water, may be found.

HYDROSULPHURETS, in chemistry. Sulphuretted hydrogen gass possesses the properties of an acid. It is absorbed by water, in considerable quantities, and the solution reddens vegetable blues; it combines also with alkalis and earths, and with several metallic oxides. The combinations which sulphuretted hydrogen forms with bases have been called hydrosulphurets.

HYGROMETER. Hygrometers are instruments which indicate the presence of water in the air, its variation in quantity, and its actual quantity existing in a given bulk of air at any given time. See METEOROLOGY.

HYMENOPTERA, in natural history, the fifth order of insects according to the Linnæan system. The insects of this order are furnished with four membranaceous wings, and also with a sting, or a process resembling one. The wasp and the bee are insects of this order.

HYOSCYAMUS, *henbane*, in botany, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 28th order, luridæ. There are eight species, one of which, viz. the niger, or common henbane, is a native of Britain. It grows on road-sides, and among rubbish.

HYPERBOLA, in geometry, the section of a cone made by a plane, so that the axis of the section inclines to the opposite leg of the cone, which in the parabola is parallel to it, and in the ellipsis intersects it. The axis of the hyperbolical section will meet also with the opposite side of the cone, when produced above the vertex. See CONIC SECTIONS.

HYPERBOLE, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged or diminished.

HYPNUM, *feather-moss*; a genus of the natural order of musci, belonging to the cryptogamia class of plants. There are fifty species, many of them natives of Great Britain; none of them, however, have any remarkable property, except the proliferum and parietinum.

HYPOTHECATE, in law, to hypothecate a ship, is to pawn it for necessaries; and a master may hypothecate either ship or goods for relief, when in distress at sea; for he represents the traders as well as owners.

HYPOTHENUSE, in geometry, the longest side of a right-angled triangle; or it is that side which subtends the right angle. Euclid, lib. I. proposition XLVII. demonstrates, that in every rectilinear right-angled triangle, the square of the hypothenuse is equal to the squares of both the other sides. This celebrated problem was discovered by Pythagoras, who is said to have sacrificed a hecatomb to the Muses, in gratitude for the discovery.

HYPOTHESIS, in general, denotes something supposed to be true, or taken for granted, in order to prove or illustrate a point in question.

HYSTRIX, *porcupine*, a genus of quadrupeds, of the order glires. The generic character is, front teeth two, both in the upper and under jaw, obliquely cut; grinders eight; body covered with spines intermixed with hairs; four toes on the fore-feet; five on the hind. There are five species, viz.

1. The common porcupine. The general length of the porcupine is about two feet from head to tail, and that of the tail about four inches. The upper parts of the animal are covered with long, hard, and sharp quills; those towards the middle and hind part of the body being longer than the rest, and measuring from nine or ten to twelve or fifteen inches in length; they are very sharp-pointed, and are variegated with several alternate black and white rings: the root, or point of attachment, is small; the head, belly, and legs, are covered with strong dusky bristles, intermixed with softer hairs: on the top of the head the hairs are very long, and curved backwards in the manner of a ruff or crest.

This animal is a native of Africa, India, and the Indian islands; it is also found in some of the warmer parts of Europe, and is said to be not very uncommon in Italy.

The porcupine feeds principally on roots, fruits, barks, and other vegetable substances: it inhabits holes or subterraneous retreats, which it is said to form into several compartments or divisions, leaving only a single hole or entrance. It sleeps much by day, and makes its excursions for food during the night. The female produces two young at a birth, and these, if taken early, are said to be easily tamed.

2. *Hystrix prehensilis*, is an American species, and is found in many of the hotter parts of that continent; particularly in Brazil, where it inhabits woods, and climbs trees; clinging occasionally to the branches by its

tail, in the manner of some of the opossums and monkies. It is said to feed not only on fruits of various kinds, but also on birds. It sleeps during the greater part of the day, concealing itself in the hollows of trees, or beneath their roots. Its voice, according to Marcgrave, resembles the grunting of a pig. Its general length is about a foot, and the tail about eighteen inches. The whole animal, except on the belly and insides of the limbs, is covered with short, strong, and very sharp spines.

3. *Hystrix Mexicana.* The Mexican porcupine, which is placed as a variety of the hystrix prehensilis in the Gmelinian edition of the Systema Naturæ, seems to be justly considered as a distinct species. It is as large, as a middle-sized dog, and is of a dusky brown colour, with very long bristles intermixed with the fur. This animal inhabits the hilly parts of Mexico, residing in woods, and feeding, like the former, on fruits, &c. It is said to be easily tamed.

4. *Hystrix macroura.* The iridescent porcupine is an animal of a very extraordinary appearance. It is of a very thick form, and is coated with short, stiff bristles, which, according to the different directions of the light, exhibit changeable colours, appearing either of a gilded green, or of a reddish tinge. If we except the gilded, or cape mole, it seems to be almost the only quadruped yet known with changeable-coloured hair.

5. *Hystrix fasciculata* is a native of Malacca. It differs from the common porcupine in several particulars, and especially in the form and length of its tail, which is naked, scaly, about a third of the length of the body, and terminated by a tuft of long flat hairs, or rather small white laminæ, resembling strips of parchment. The body measures fifteen or sixteen inches, and is consequently less than that of the European porcupine.

6. *Hystrix dorsata* is a native of the northern parts of America, and is not uncommon in Canada. It is a short thick-bodied animal, approaching somewhat to the form of a beaver, and is remarkable for the length and fulness of its fur, which is soft, of a dusky brown colour, and intermixed with longer and coarser hairs with whitish tips. It is said to feed principally on the bark of the juniper tree. It drinks by lapping, in the manner of a dog. It resides in holes under the roots of trees, on which, like some others of this genus, it often climbs, and is thus killed by the American Indians, who consider it as a useful article of food; they also use the quills by way of fringes, and for the purpose of ornamenting their boxes, &c

I & J.

I, the ninth letter of the alphabet, used as a numeral, signifies no more than one, and stands for so many units as it is repeated times: thus, I, one; II, two; III, three, &c. and when put before a higher numeral, it subtracts itself, as IV, four; IX, nine, &c. but when set after it, so many are added to the higher numeral, as there are I's added; thus VI is 5+1, or six; VII, 5+2, or seven; VIII, 5+3, or eight. The ancient Romans likewise used IƆ for 500, CIƆ for 1000, IƆƆ for 5000, CCIƆƆ, for 10,000, IƆƆƆ for 50,000, and CCCIƆƆƆ for 100,000. Farther than this, as Pliny observes, they did not go in their notation; but when necessary, repeated the last number, as CCCIƆƆƆ, CCCIƆƆƆ for 200,000: CCCIƆƆƆ, CCCIƆƆƆ, CCCIƆƆƆ for 300,000; and so on.

Besides the vowel, there is the jod consonant; which, because of its different pronunciation, has likewise a different form, thus, J. j. In English it has the soft sound of *g*, nor is used but when *g* soft is required before vowels, where *g* is usually hard: thus we say *jack*, *jet*, *join*, &c. instead of *gack*, *get*, *goin*, &c. which would be contrary to the genius of the English language.

JACK, in mechanics, an instrument of common use for raising heavy timber, or very great weights of any kind. The common kitchen jack is a compound engine, where the weight is the power applied to overcome the friction of the parts, and the weight with which the spit is charged; and a steady and uniform motion is obtained by means of the fly.

Jack, in naval affairs, a sort of flag, or colours, displayed from a staff erected on the outer end of a ship's bowsprit. In the British navy the jack is a small union flag; but in merchant ships the union is bordered with red.

Jack, *smoke.* See Smoke Jack.

Jack *in the box*, a large wooden male screw, turning in a female one, which forms the upper part of a strong wooden box, shaped like a frustrum of a pyramid. It is used by means of levers passing through holes in it, as a press in packing, and for other purposes.

Jack-*flag*, in a ship, that hoisted up at the sprit-sail top-mast head.

JACKALL. See Canis.

JACOBUS, an ancient gold coin worth twenty-five shillings.

JACQUINIA, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is decemfid; the stamina inserted into the receptacle; the berry monospermous. There are four species, shrubs of South America.

JADE. See Nephrite.

JALAP is the root of the convolvulus jalappa. It derives its name from Xalapa, a town of Mexico, in the environs of which it grows plentifully. It is also found among the sands of Vera Cruz. This plant resembles in appearance the convolvulus of our hedges.

By M. Henry's analysis, the constituents of three different varieties of this root are,

	Jal. leger.	Jal. semi	Jal. pique
Resin,	60	48	72
Extract,	75	140	125
Starch,	95	102	103
Woody fibre,	270	210	200
	500	500	500

IAMBIC, in ancient poetry, a sort of verse so called from its consisting, either wholly or in great part, of iambuses. The word is applied also to a particular kind of Latin verse, of

which the simple foot consists of a short and long syllable.

JAPANNING is properly the art of varnishing and painting ornaments on wood, in the same manner as is done by the natives of Japan in the East Indies.

The substances which admit of being japanned are almost every kind that are dry and rigid, or not too flexible; as wood, metals, leather, and paper, prepared for the purpose. Wood and metals do not require any other preparation but to have their surfaces perfectly even and clean; but leather should be securely strained, either on frames or on boards; as its bending, or forming folds, would otherwise crack and force off the coats of varnish. Paper should be treated in the same manner, and have a previous strong coat of some kind of size; but it is rarely made the subject of japanning till it is converted into paper mache, or wrought by other means into such form, that its original state, particularly with respect to flexibility, is changed.

One principal variation from the method formerly used in japanning is, the omitting any priming, or undercoat, on the work to be japanned. In the older practice, such a priming was always used; the use of which was to save in the quantity of varnish, by filling up the inequalities in the surface of the substance to be varnished. But there is a great inconvenience arising from the use of it, that the Japan coats are constantly liable to be cracked, and peeled off, by any violence, and will not endure near so long as the articles which are japanned without any such priming.

Of the nature of Japan grounds.—When a priming is used, the work should first be prepared by being well smoothed with fish-skin or glass-paper, and being made thoroughly clean, should be brushed over once or twice with hot size, diluted with two-thirds water, if it is of the common strength. The priming should then be laid on as even as possible, and should be formed of a size, of a consistency between the common kind and glue, mixed with as much whiting as will give it a sufficient body of colour to hide the surface of whatever it is laid upon, but not more. This must be repeated till the inequalities are completely filled up, and then the work must be cleaned off with Dutch rushes, and polished with a wet rag.

When wood or leather is to be japanned, and no priming is used, the best preparation is to lay two or three coats of coarse varnish, composed in the following manner. Take of rectified spirit of wine one pint, and of coarse seed-lac and resin each two ounces; dissolve the seed-lac and resin in the spirit, and then strain off the varnish. This varnish, as well as all others formed of spirit of wine, must be laid on in a warm place; and if it can be conveniently managed, the piece of work to be varnished should be made warm likewise; and for the same reason, all dampness should be avoided; for either cold or moisture chills this kind of varnish, and prevents its taking proper hold of the substance on which it is laid.

When the work is so prepared, or by the priming with the composition of size and whiting above described, the proper japan ground must be laid on, which is much the best formed of shell-lac varnish, and the colour desired, except white, which requires a peculiar treatment; and if brightness is wanted, then also other means must be pursued. The colours used with the shell-lac varnish may be any pigments whatever, which give the tint of the ground desired. As metals never require to be under-coated with whiting, they may be treated in the same manner as wood or leather.

Method of painting Japan work.—Japan work ought properly to be painted with colours in varnish; though, for the greater dispatch, and in some very nice work in small, for the freer use of the pencil, the colours are sometimes tempered in oil; which should previously have a fourth part of its weight of gum animi dissolved in it; or in default of that, gum sandarach, or gum mastich. When the oil is thus used, it should be well diluted with oil of turpentine, that the colours may lie more evenly and thin; by which means fewer of the polishing or upper coats of varnish become necessary. When a sufficient number of coats is thus laid on, the work is fit to be polished; which must be done, in common cases, by rubbing it with a rag dipped in tripoli, or rottenstone, finely powdered; but, towards the end of the rubbing, a little oil of any kind should be used along with the powder; and when the work appears sufficiently bright and glossy, it should be well rubbed with the oil alone, to clean it from the powder, and give it a still brighter lustre.

JARGON. See Zircon.

JASIONE, a genus of the monogamia order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, campanaceæ. There are four species, shrubs of the West Indies.

JASMINUM, *Jasmine*, or Jessamine-tree, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 44th order, sepiariæ. The corolla is salver-shaped, the berry dicoccous; the seeds arillated, the antheræ within the tube. There are 17 species.

JASPER. A sub-species of the rhomboidal quartz of Professor Jameson. He enumerates five kinds: Egyptian jasper, striped, porcelain, common, and agate jasper.

1. *Egyptian jasper*, of which there are red and brown. The first is flesh-red, blood-red, yellow, and brown, in ring-shaped delineations. In roundish pieces. It is found imbedded in red clay-ironstone at Baden, and is cut into ornaments.

The *brown* has its various shades of colour disposed in concentric stripes, alternating with black stripes. In spheroidal masses. Lustre glimmering. Fracture conchoidal. Feebly translucent on the edges. As hard as hornstone. Specific gravity 2.6. It is infusible. It occurs loose in the sands of Egypt. It is cut into ornaments.

2. *Striped jasper.* Colours, grey, green, yellow, red, arranged in stripes, in flamed, or spotted delineations. Massive in whole beds. Dull. Fracture conchoidal. Opaque. Less hard than Egyptian jasper. Rather easily frangible. Specific gravity 2.5. It occurs in secondary clay-porphyry in the Pentland-hills, and near Friburg in Saxony. It receives a fine polish.

3. *Porcelain jasper.* Colours grey, blue, yellow, generally of one colour, or with clouded delineations. Massive, and cracked in all directions. Lustre glistening. Fracture con-

choidal. Opaque. Easily frangible, and not very hard. Specific gravity, 2.5. Fuses into a white or grey glass. It is always found along with burnt clay and earth slags. It is found on the coast of Fifeshire, in Shropshire, and Warwickshire, and some parts of Germany, where immense beds of coal appear.

4. *Common jasper.* Colours red and brown. Massive. Lustre, from shining to dull. Fracture conchoidal. Opaque. Hard in a low degree. Rather easily frangible. Specific gravity 2.6. Infusible before the blowpipe, becoming at last white. It occurs principally in veins as a constituent of agate. It is found in the Pentland-hills, and in trap and transition rocks in Aryshire and Dumfries-shire. It receives a good polish.

5. *Agate jasper.* Colours yellowish-white and reddish-white. Massive. Dull. Fracture flat conchoidal. Opaque. Hard in a low degree. It occurs in layers in agate balls, in many places.

JATROPHA, the *cassada plant*, a genus of the monodelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricocca. There are nine species, of which the most remarkable are: 1. The curcas or English physic nut. 2. The gossypifolia, cotton-leaved jatropha. 3. The multifida, or French physic nut. 4. The manihot, or bitter cassada, has palmated leaves; the lobes lanceolate, very entire, and polished. 5. The janipha, or sweet cassada, has palmated leaves, with lobes very entire; the intermediate leaves lobed with a sinus on both sides. 6. The elastica, or hevea guianensis, with ternate leaves elliptic, very entire, hoary underneath, and longly petiolated. See CAOUTCHOUC.

The root of bitter cassada has no fibrous or woody filaments in the heart, and neither boils nor roasts soft. The sweet cassada has all the opposite qualities. The bitter, however, may be deprived of its noxious qualities (which reside in the juice) by heat. Cassada bread, therefore, is made of both, thus: the roots are washed and scraped clean, then grated into a tub; after this, they are put into a hair bag, and strongly pressed, to squeeze out the juice, and the meal is dried in a hot stone bason over the fire. Cassada roots yield a great quantity of starch, which the Brazilians export in little lumps under the name of tapioca.

JAY. See CORVUS.

IBEX, in zoology. See CAPRA.

IBIS. See TANTALUS.

ICE. See CONGELATION.

ICE-*house*, a building contrived to preserve ice for the use of a family in the summer season. It is generally sunk some feet in the ground in a very shady situation, and covered with thatch.

ICELAND-*agate*, a precious stone met with in the islands of Iceland and Ascension, employed by the jewellers as an agate, though too soft for the purpose. It is supposed to be a volcanic product; being solid, black, and of a glassy texture. When held between the eye and the light, it is semitransparent, and greenish, like the glass bottles which contain much iron. In the islands which produce it, such large pieces are met with that they cannot be equalled in any glass-house.

ICHNEUMON *fly*, the name of a genus of flies of the hymenoptera order. The generic character is, mouth with jaws, without tongue: antennæ with more than thirty joints; abdomen in most species footstalked; piercer exserted, with a cylindric bivalve sheath. The animals of this genus provide for the support of their offspring in a manner highly extraordinary, depositing their eggs in the bodies of other living insects, and generally in those of caterpillars. These eggs in a few days hatch, and the young larvæ, which resemble minute white maggots, nourish themselves with the juices of the unfortunate animal, which however continues to move about and feed till near the time of its change to a chrysalis, when the young brood of ichneumon-larvæ creep out by perforating the skin in various places, and each spinning itself up in a small oval silken case, changes into a chrysalis, the whole number forming a groupe on the shrivelled body of the caterpillar which had afforded them nourishment; and after a certain period emerge in the state of complete ichneumons.

ICHNOGRAPHY, in perspective, the view of any thing cut off by a plane parallel to the horizon, just at the base of it.

ICHTHYOCOLLA. See ACCIPENSER and GELATINA.

ICHTHYOLITHUS, in natural history, the body or parts of a fish changed into a fossil substance. Four species are enumerated. They are seldom found whole, but in different parts, as the head, gill-covers, and other bones, fins, tails, tendrils, or scales, in a grey slaty swine-stone, or impressed on shistose marble, and sometimes penetrated with bitumen.

ICHTHYOLOGY, *ιχθυολογια*, the science of fishes, or that branch of zoology which treats of fishes. See PISCES.

ICOSAHEDRON, in geometry, a regular solid, consisting of twenty triangular pyramids, whose vertices meet in the centre of a sphere, supposed to circumscribe it; and, therefore, have their height and bases equal; wherefore the solidity of one of those pyramids multiplied by twenty, the number of bases, gives the solid content of the icosahedron.

ICOSANDRIA, from *εικοσι* "twenty," and *ανηρ*, "a man or husband;" the name of the 12th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with twenty or more stamina, that are inserted into the inner side of the calyx or petals. See BOTANY.

IDEAOLOGY. The philosophy of the human mind. We are conscious of our own existence; and in this consciousness we perceive a certain variety or successive change, which we distinguish by the name of thought. It seems as if it would be a vain attempt to investigate by what physical operations the proceedings of the mind may be caused, supported, or governed. The primary objects of thought are derived from our sensations or perceptions. We can form no conception of any subject of thought which shall not be referable to the senses. During the actual time of sensation we suppose ourselves to be operated upon, by some beings or objects which constitute no part of ourselves; and we do not hesitate to infer from those sensations, that an external universe does actually subsist. Berkeley, Hume, and others, have made this a subject of question; and it must be confessed, that we have no absolute proof respecting it. From the certainty, however that we ourselves do not cause the changes

which produce sensation in us, we are irresistibly impelled to an affirmative decision of this question.

In many instances, the sensations we experience afford some resemblance of the objects which cause them, as in the figures of bodies; but in others, it is probable that no such resemblance exists, as in colours, sounds, &c. A distinction has therefore very properly been made, between that which is perceived, and the cause of the perception: and, moreover, as we find that effects, similar to our antecedent perceptions, may and do take place, though the organs of sense are not then acted upon, we make a further distinction between these last, and the perceptions themselves. We call them ideas. They not only resemble the perceptions, as individually considered, but likewise make their appearance in the same arrangement or order of recurrence. We think we perform a positive act, in many instances, in bringing them forward, which we call an act of the memory, or recollection; and their concomitant appearance, or the succession of ideas by recollection, in the similarity or the order of the sensations, has been called the association of ideas. The same term is likewise applied, when we speak of the recurrence, in idea, of an entire contemporaneous sensation, in consequence of part of it being brought forward in the memory.

Much discussion has taken place among philosophers, respecting the origin and nature of our ideas; in which it must be confessed that a mis-application of terms, a confusion of intellectual research, with an admixture of theological notions, and several other causes, have united to render a plain subject considerably obscure, even in the hands of men of much talent and acuteness.

IDENTITY, denotes that by which a thing is itself, and not any thing else.

IDIOM, among grammarians, properly signifies the peculiar genius of each language, but is often used in a synonymous sense with dialect.

IDIOSYNCRASY, among physcians, denotes a peculiar temperament of body, whereby it is rendered more liable to certain disorders, than persons of a different constitution usually are.

IDIOTS, in law. An idiot is a fool or madman from his nativity. According to the statute 17 Edward II. c. 9, the king shall have the custody of the lands of natural fools, taking the profits of them without waste or destruction, and shall find them necessaries. And, after the death of them, he shall render it to the right heir.

But it seldom happens, that a jury finds a man an idiot from his nativity, but only *non compos mentis*, from some particular time; in which case, he comes under the denomination of a lunatic, of whose lands the king shall not have the profit, but is accountable for the same to the lunatic when he comes to his right mind, or to his executors or administrators.

An idiot, or person *non compos*, may inherit, and purchase, and if he marry and die, his wife shall be endowed. It is a general rule, that idiots and lunatics, being incapable of judging between good and evil, are punishable by no criminal prosecution whatsoever. Acts solemnly acknowledged by them in a court of record, as fines and recoveries, and the uses declared on them, are good, and cannot be avoided by themselves or representatives. But during their lunacy they are incapable of making any will or testament, as are also persons grown childish from extreme old age. When an idiot sues, or defends, he must appear; but a lunatic shall appear by guardian or by attorney.

JELLY, in chemistry. If we press out the juice of ripe blackberries, currants, and many other fruits, and allow it to remain for some time in a state of rest, it partly coagulates into a tremulous soft substance, well known by the name of jelly. If we pour off the uncoagulated parts, and wash the coagulum with a small quantity of water, we obtain jelly approaching to a state of purity.

In this state it is nearly colourless, unless tinged by the peculiar colouring matter of the fruit. It is scarcely soluble in cold water, but very soluble in hot water; and when the solution cools, it again coagulates into the form of a jelly. When long boiled, it loses the property of gelatinizing by cooling, and becomes analogous to mucilage. This is the reason that in making currant-jelly, or any other jelly, when the quantity of sugar added is not sufficient to absorb all the watery parts of the fruit, and consequently it is necessary to concentrate the liquid by long boiling, the mixture often loses the property of coagulating, and the jelly, of course, is spoiled.

JESUITS, in church history, or the society of Jesus, a celebrated religious order in the Romish church, founded by Ignatius Loyoly, a Spaniard, who in the year 1738, assembled ten of his companions at Rome, and proposed to form a new order, when it was agreed to add to the three ordinary vows of chastity, poverty, and obedience, a fourth, which was to go wherever the Pope should command, to make converts. They were admitted on their own terms; but the order was abolished, on account of the enormities committed by them, in 1773.

JESUIT'S-*bark*. See CINCHONA and PHARMACY.

JET. See COAL.

JET D'EAU. See HYDRAULICS.

JEWS, in church history, the descendants of Judah, the son of Jacob, and of the Israelites, commonly denominated the Twelve Tribes of Israel. This name was first given to those Jews who returned from the captivity of Babylon, because the tribe of Judah made the most conspicuous figure among them.

The following is a summary of their religious creed 1. That God is the creator and active supporter of all things. 2. That God is one, and eternally unchangeable. 3. That God is incorporeal, and cannot have any material properties. 4. That God shall eternally subsist. 5. That God alone above is to be worshipped. 6. That whatever has been taught by the prophets is true. 7. That Moses is the head and father of all contemporary doctors, and of all those who lived before, or shall live after him. 8 That the law was given by Moses. 9. That the law shall always exist, and never be altered. 10. That God knows all the thoughts and actions of men. 11. That God will reward the observance and punish the breach of his laws. 12. The Messiah is to come, though he tarry a

long time. 13. That there shall be a resurrection of the dead when God shall think fit. In England, in former times, the Jews and all their goods belonged to the chief lord where they lived. By stat. Edward I. the Jews, to the number of 15,000, were banished out of England; and never returned till Oliver Cromwell readmitted them. Whenever any Jew shall present himself to take the oath of abjuration in pursuance of the 10 Geo. III. c. 19, the words "upon the true faith of a Christian" shall be omitted. If Jewish parents refuse to allow their protestant children a maintenance suitable to their fortune, the lord chancellor, upon complaint, may make such order therein as he may think proper.

IGNIS FATUUS. A luminous appearance or flame, frequently seen in the night in different country places, and called in England *Jack with a lantern, or Will with the wisp.* It seems to be mostly occasioned by the extrication of phosphorus from rotting leaves and other vegetable matters. It is probable, that the motionless ignes fatui of Italy which are seen nightly on the same spot, are produced by the slow combustion of sulphur, emitted through clefts and apertures in the soil of that volcanic country.

JIB, the foremost sail of a ship, being a large stay-sail extended from the outer end of the bowsprit prolonged by the jib-boom, towards the fore-top-mast-head.

ILEX, *the holm or holly tree,* a genus of the tetragynia order, in the tetrandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The calyx is quadridentated; the corolla rotaceous; there is no style: the berry is monospermous. There are sixteen species of this genus; but the most remarkable is the aquifolium, or common holly. Sheep in the winter are fed with croppings of holly. Birds eat the berries. The bark fermented, and afterwards washed from the woody fibres, makes the common birdlime. The plant makes an impenetrable fence, and bears cropping; however it is not found in all respects to answer for this purpose equally well with the hawthorn.

The common holly affords a most striking example of the wise intention of the great Author of nature, in furnishing some plants with spines and prickles, which disappear after they have acquired a degree of height and strength sufficient to protect them from being eaten by cattle. This is finely described by Southey in the following lines.

O reader! hast thou ever stood to see
The holly-tree?
The eye that contemplates it well perceives
Its glossy leaves,
Ordered by an Intelligence so wise,
As might confound the atheist's sophistries.

Below, a circling fence, its leaves are seen,
Wrinkled and keen:
No grazing cattle, through their prickly round,
Can reach to wound:
But, as they grow *where nothing is to fear,*
Smooth and *unarmed* the pointless leaves appear.

ILLUMINATING, a kind of miniature-painting, anciently much practised for illustrating and adorning books. Besides the writers of books, there were artists whose profession was to ornament and paint manuscripts, who were called illuminators: the writers of books first finished their part, and the illuminators embellished them with ornamented letters and paintings. We frequently find blanks left in manuscripts for the illuminators which were never filled up. Some of the ancient manuscripts are gilt and burnished in a style superior to later times. Their colours were excellent, and their skill in preparing them must have been very great.

IMAGE. See Optics.

IMAGINATION, a power or faculty of the mind, whereby it conceives and forms ideas of things communicated to it by the outward organs of sense.

IMBRICATED, among botanists, an appellation given to such leaves of plants, as are placed over one another like the tiles of a house.

IMITATIVE, in music, a term applicable to that music which is composed in imitation of the effects of some of the operations of nature, art, or human passion, as the rolling of thunder, swiftness of lightning, agitation of the sea, bellowing of the winds or waves, &c.

IMMERSION, that act by which any thing is plunged into water, or other fluid. See Fluid.

Immersion, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it; being as it were enveloped and hidden in the rays of that luminary. It also denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth; and the same term is also used with regard to an eclipse of the sun, when the disk of the moon begins to cover it. In this sense emersion stands opposed to immersion, and signifies the moment wherein the moon begins to come out of the shadow of the earth, or the sun begins to show the parts of his disk which were hid before.

IMPARLANCE, in law, a petition in court for a day to consider or advise what answer the defendant shall make to the plaintiff's action, and is the continuance of the cause till another day, or a longer time given by the court.

An imparlance is general or special: general is when it is entered in general terms, without any special clause therein; special is where the defendant desires a further day to answer.

IMPEACHMENT, is the accusation and prosecution of a person in parliament, for treason or other crime and misdemeanor. An impeachment before the lords by the commons of Great Britain, is a presentment to the most high and supreme court of criminal jurisdiction, by the most solemn, grand inquest of the whole kingdom. The articles of impeachment are a kind of bill of indictment, found by the house of commons, and afterwards tried by the lords. By stat. 12 and 13 W. c. 2. no pardon under the great seal shall be pleadable to an impeachment by the commons in parliament.

In the case of Warren Hastings, in the year 1791, it was solemnly determined that impeachments do not abate by a dissolution of parliament.

Impeachment *of waste,* signifies a restraint from committing of waste upon lands and tenements; and therefore he that has a lease without impeachment of waste, has by that a property or interest given him in the houses and trees, and may make waste in them without being impeached for it.

IMPEDIMENTS *in law.* Persons under impediments are those within age, under cover-

ture, *non compos mentis*, in prison, or beyond seas, who by a saving in our laws, have time to claim and prosecute the right, after the impediments removed, in case of fines levied, &c.

IMPENETRABILITY. See DIVISIBILITY.

IMPERATIVE, one of the moods of a verb, used when we would command, entreat, or advise: thus, *go, read, take pity, be advised,* are imperatives in our language.

IMPERFECT, something that is defective, or that wants some of the properties found in other beings of the same kind: thus mosses are called imperfect plants, because almost all the parts of fructification are wanting in them; and for the like reason is the appellation imperfect given to the fungi and submarine plants.

IMPERFECT *numbers,* such whose aliquot parts taken together do either exceed, or fall short of that whole number of which they are parts: they are either abundant or deficient.

IMPERSONAL *verb,* in grammar, a verb to which the nominative of any certain person cannot be prefixed; or, as others define it, a verb destitute of the two first and primary persons.

IMPETIGENES, in medicine, descriptive of those disorders which, from a general bad habit, manifest themselves principally by disfiguring the skin and external parts of the body.

IMPETUS, in mechanics, the force with which one body impels or strikes another.

IMPLEAD, to sue or prosecute by course of law.

IMPLICATION, in law, is where the law implies something that is not declared between parties in their deeds and agreements, and when our law gives any thing to a man, it gives by implication whatever is necessary for enjoying it.

IMPORTATION, the act of bringing goods into a country from foreign parts. It has generally been considered, that for any country to carry on a profitable trade, it is necessary that the value of the goods sent out of it should be greater than that of the articles imported: this, however, is a very erroneous axiom, unless it is understood with great limitations. All articles of merchandize, imported merely for re-exportation, and also such as are used or worked up in our own manufactures, are far from being hurtful to our commerce; and may even, in many respects, be deemed of equal profit with our own native commodities. It is therefore an excess of such importations alone as are either for mere luxury or mere necessity, or for both together, which is disadvantageous to the country.

IMPOSTS, in architecture, the capitals of pillars, or pilasters, which support arches. An impost sometimes called chaptrel, is a sort of a plinth, or a little cornice, which crowns a pier, and supports the first stone whence an arch or vault commences.

IMPOTENCE, in the ecclesiastical law, is an inability of generation, or propagating the species, and forms a cause of divorce a vinculo matrimonii, as being merely void, and requiring only a sentence declaratory of its being so.

IMPRESSING *men.* The power of impressing seamen for the sea-service, by the King's commission, has been a matter of some dispute, and submitted to with great reluctance, though it has very clearly and learnedly been shown by Sir Michael Forster, that the practice of impressing seamen for the sea-service, and granting power to the Admiralty for that purpose, is of a very ancient date, and has been continued by a series of precedents, to the present time, whence it has been held to be a part of the common law; and though no statute has expressly declared this power to be in the crown, many of them very strongly imply it. Landmen, entering into the merchant service, and apprentices, are exempt for two years from the impress, and all apprentices to the sea-service under eighteen.

IMPRISONMENT, is the restraint of a man's liberty under the custody of another, and extends not only to a gaol, but a house, stocks, or where a man is held in the street, or any other place; for in all these cases, the party so restrained is said to be a prisoner.

None shall be imprisoned but by the lawful judgment of his peers, or by the law of the land. Magna Charta.

IMPRISONMENT, *false.* To constitute the injury of false imprisonment, two points are necessary: the detention of the person, and the unlawfulness of such detention.

IMPROPRIATION, is properly so called when a benefice ecclesiastical is in the hands of a layman; and appropriation when in the hands of a bishop, college, or religious house, though sometimes these terms are confounded. It is said there are 3845 impropriations in England.

IMPULSE, or IMPULSIVE FORCE, the same with impetus. See MECHANICS.

INARCHING, in gardening. See GRAFTING.

INCH, a well-known measure of length, being the twelfth part of a foot, and equal to three barley corns in length.

INCIDENCE, in mechanics, denotes the direction in which one body strikes on another See MECHANICS and OPTICS.

INCLINATION, is a word frequently used by mathematicians, and signifies the mutual approach, tendency, or leaning, of two lines or two planes towards each other, so as to make an angle.

INCLINED *plane,* in mechanics, one that makes an oblique angle with the horizon. See MECHANICS.

INCLOSURES. Any person who shall wilfully or maliciously destroy or damage any fence made for inclosing any common waste or other lands, in pursuance of any act of parliament, shall be transported for seven years.

INCOMBUSTIBLE. See COMBUSTION.

INCOME *tax,* a direct contribution of a certain proportion of the annual gains of individuals for the public service, which has become an important branch of the revenue of Great Britain. An attempt was made in 1702 to levy a tax of this description; but it proved unproductive, and was discontinued. Towards the end of the year 1798, Mr. Pitt proposed, in lieu of the additional assessed taxes, a general tax on income. The act was passed 9th January, 1799; and the duties imposed by it were, ten per cent. on all incomes of 200*l.* per annum and upwards, and lesser proportions on incomes between that amount and 60*l.* per annum, which paid ten shillings per annum: incomes below 60*l.* a year were wholly exempt. The great object of this tax was, to raise a considerable proportion of the public supplies within the

year, and to liquidate within a short time what might be further raised by loan; but it being a tax which from its commencement had been very unpopular, it was repealed in April, 1802, and the charges upon it transferred to the Consolidated Fund.

In 1803 the income tax was revived, with some alterations in the mode of collecting it, under the title of the property tax: the rate at which it was now imposed was 5 per cent. on all incomes above 150*l.* per annum, and lesser proportions on incomes between that amount and 60*l.* per annum. In 1805 it was increased to 6¼ per cent.; and in 1806 it was raised to the original rate at which it had been imposed, or 10 per cent., while the scale of lesser rates was made to comprehend all incomes amounting to 50*l.* per annum. By this means, and by deducting the tax on the dividends of the public funds at the bank, and abolishing most of the former abatements and exemptions, the sum raised by it has been considerably augmented, the estimated produce being as follows:

1804 at 1*s.* in the pound............	£4,650,000
1805 at 1*s.* 3*d.* ditto..................	5,937,500
1806 at 2*s.*........ditto..................	11,500,000

An income tax, if it could be so regulated as to bear a just proportion to the different modes in which the incomes of individuals arise, and did not extend to such amounts of income as are absolutely necessary for subsistence, would become the most equitable, as well as the most productive mode of taxation.

INCOMMENSURABLE, a term in geometry, used where two lines, when compared to each other, have no common measure, how small soever, that will exactly measure them both. And in general two quantities are said to be incommensurable, when no third quantity can be found that is an aliquot part of both.

INCOMPLETE, in botany, a term used to denote the sixteenth class of the Linnæan "methodus calycina," consisting of plants whose flowers want either the calyx or petals.

INCORPORATION, *power of.* To the erection of any corporation the king's consent is necessary, either impliedly or expressly given. The methods by which the king's consent is expressly given are either by act of parliament or charter.

INCREMENT, is the small increase of a variable quantity. Sir Isaac Newton calls these increases "moments," and observes, that they are proportional to the velocity or rate of increase of the flowing or variable quantities, in an indefinitely small time.

INCUBUS, or **NIGHT-MARE**, a disease which consists in a spasmodic contraction of the muscles of the breast, usually happening in the night, and attended with very painful difficulty of respiration and great anxiety; most frequently caused by eating heavy suppers.

INDEFINITE, or **INDETERMINATE**, that which has no certain bounds; or to which the human mind cannot affix any.

INDEFINITE is also used in the schools to signify a thing that has but one extreme; for instance, a line drawn from any point and extended infinitely.

INDEMNITY, in law, the saving harmless; or, a writing to secure one from all damage and danger that may ensue from any act. An indemnity in regard to estates is called a warranty.

INDENTED, in heraldry, is when the outline of an ordinary is notched like the teeth of a saw.

INDENTED *line*, in fortification, the same with what the French engineers call redent; being a trench and parapet running out and in, and much used in irregular fortification.

INDENTURE, is a writing containing a conveyance between two or more, indented or cut unevenly, or in and out, on the top or side, answerable to another writing that likewise comprehends the same words. Formerly when deeds were more concise than at present, it was usual to write both parts on the same piece of parchment, with some words or letters written between them, through which the parchment was cut, either in a straight or indented line, in such a manner as to leave half the word on one part, and half on the other; and this custom is still preserved in making out the indentures of a fine.

But at last, indenting only has come into use without cutting through any letters at all; and it seems at present to serve for little other purpose than to give name to the species of the deed.

INDEPENDENTS, a sect of protestants in England and Holland, so called from their independency on other churches, and their maintaining that each church or congregation has sufficient power to act and perform every thing relating to religious government within itself, and is no way subject or accountable to other churches or their deputies.

INDEX, in arithmetic and algebra, shows to what power any quantity is involved, and is otherwise called *exponent.*

INDEX *of a logarithm*, that which shows of how many places the absolute number, belonging to a logarithm, doth consist; and of what nature it is, whether an integer or fraction.

INDICATIVE, in grammar, the first mood or manner of conjugating a verb, by which we simply affirm, deny, or ask something; as, *amant*, they love; *non amant*, they do not love: *amantne*, do they lo

INDICTION, in chronology, a cycle of 15 years. The Roman or papal indiction, which is that used in the pope's bulls, begins on the 1st of January; and by it the popes have dated their acts ever since Charlemagne made them sovereigns. But besides this, there are other two kinds of indiction, viz. that of Constantinople beginning on the first of September; and the imperial or Cæsarian indiction, which commenced on the 14th of September.

INDICTMENT, is a written accusation of one or more persons of a crime or misdemeanor, preferred to, and presented on oath by, a grand jury.

An indictment may be found on the oath of one witness only, unless it is for high treason, which requires two witnesses; and unless in any instance it is otherwise specially directed by acts of parliament.

The sheriff of every county is bound to return to every session of the peace, and every commission of oyer and terminer, and of general gaol-delivery, 24 good and lawful men, of the county, some out of every hundred, to inquire, present, do, and execute, all those things which on the part of our lord the [illegible]g, shall then and

there be commanded therein. As many as appear upon this pannel are sworn of the grand jury, to the amount of twelve at the least, and not more than twenty-three, that twelve may be a majority. This grand jury is previously instructed in the articles of their inquiry, by a charge from the judge on the bench. They then withdraw from court to sit and receive indictments preferred to them in the name of the king, but at the suit of any private prosecutor; and they are only to hear evidence on behalf of the prosecution.

They may not find part of an indictment true and part false; but must either find a true bill or ignoramus for the whole.

All capital crimes whatever, and all kinds of inferior crimes which are of a public nature, may be indicted, but no injuries of a private nature, unless they in some degree concern the king. And generally where a statute prohibits a matter of public grievance, or commands a matter of public convenience, every disobedience of such statute is punishable, not only at the suit of the party grieved, but also by way of indictment. Yet if the party offending has been fined in an action brought by the party, such fine is a good bar to the indictment.

If several offenders commit the same offence, they may be joined in one indictment; as if several commit a robbery, or burglary, or murder.

No indictment for high treason, or misprision thereof (except indictments for counterfeiting the king's coin, seal, sign, or signet,) nor any process or return thereupon, shall be quashed for mis-reciting, mis-spelling, false or improper Latin, &c. unless exception concerning the same is taken, and made in the respective court where the trial shall be, by the prisoner or his counsel assigned, before any evidence given in open court on such indictment.

No indictment can be good without expressly shewing some place wherein the offence was committed, which must appear to have been within the jurisdiction of the court. There are several emphatical words which the law has appropriated for the description of an offence, which no circumlocution will supply: as *feloniously*, in the indictment of any felony; *burglariously*, in an indictment of burglary, and the like. An indictment on the black act for shooting at any person must charge that the offence was done wilfully and maliciously. It is enacted, that no clerk of assize, clerk of the peace, or other person, shall take any money of any person bound over to give evidence against a traitor or felon for the discharge of his recognizance, nor take more than 2*s.* for drawing any bill of indictment against any such felon, on pain of 5*l.* to the party grieved, with full costs.

Every person charged with any felony or other crime, who shall on his trial be acquitted, or against whom no indictment shall be found by the grand jury, or who shall be discharged by proclamation for want of prosecution, shall be immediately set at large in open court, without payment of any fee to the sheriff or gaoler, but in lieu thereof, the treasurer, on a certificate signed by one of the judges or justices before whom such prisoner shall have been discharged, shall pay out of the general rate of the county or district, such sum as has been usually paid, not exceeding 13*s.* [illegible]*d.*

But an action cannot be brought by the person acquitted against the prosecutor of the indictment, without obtaining a copy of the record of his indictment and acquittal; which in prosecutions for felony it is not usual to grant, if there is the least probable cause to found such prosecution upon. But an action on the case for a malicious prosecution may be founded on such an indictment whereon no acquittal can be, as if it is rejected by the grand jury, or is coram non judice, or is insufficiently drawn; for it is not the danger of the plaintiff, but the scandal, vexation, and expence, upon which this action is founded. However any probable cause for preferring it is sufficient to justify the defendant, provided it does not appear that the prosecution was malicious.

INDIGO. A blue colouring matter extracted from a plant called anil, or the indigo plant. In the preparation of this drug, the herb is put into a vat or cistern, called the steeping trough, and there covered with water. The matter begins to ferment sooner or later, according to the warmth of the weather and the maturity of the plant; sometimes in six or eight hours, and sometimes in not less than twenty. The liquor grows hot, throws up a plentiful froth, thickens by degrees, and acquires a blue colour inclining to violet. At this time, without touching the herb, the liquor impregnated with its tincture is let out by cocks in the bottom into another vat placed for that purpose, so as to be commanded by the first.

In the second vat, called the beating vat, the liquor is strongly and incessantly beaten with a kind of buckets fastened to poles, till the colouring matter is united into a body. As soon as it is judged, from the blue colour of the liquid, that the beating is sufficient, it is left at rest for two hours; after which the clear liquor is drawn off by cocks in the side of the vat, and the blue part is discharged by another cock into a third vat, where it is suffered to settle for some time longer; then conveyed in a half fluid state into bags of cloth, to strain off more of its moisture; and lastly, exposed to the air in the shade in shallow wooden boxes, till it is thoroughly dry.

Bergmann concludes, from his analysis, that 100 parts of good indigo contain of mucilaginous matter separable by water 12, resinous matter soluble in alcohol 6, earthy matter taken up by the acetic acid, which does not attack the iron, here, in the state of oxide, 22, oxide of iron taken up by the muriatic acid 13.

There remained 47 parts, which are the colouring matter, nearly in a state of purity, and afforded by distillation, carbonic acid 2, alkaline liquor 8, empyreumatic oil 9, coal 23.

The blue vat of the dyer contains indigo deoxidized by protoxide of iron, and rendered soluble in its yellow-green state by lime water. If a portion of this solution be exposed to the air, in a shallow vessel, the indigo will speedily absorb oxygen, and precipitate in its usual state of an insoluble blue powder. This being dried, and digested in a mixture of alcohol and muriatic acid, becomes also pure indigo by the abstraction of all the resin and lime. In this state, it is a soft powder, of an intensely deep blue, verging sometimes on purple. It is unchangeable by the air.

INDIVIDUAL, in logic, a particular being of any species, or that which cannot be divided

into two or more beings equal or alike. The usual division in logic is made into genera, those genera into species, and those species into individuals.

INDIVISIBLE, among metaphysicians. A thing is said to be indivisible absolute, absolutely indivisible, that is a simple being, and consists of no parts into which it may be divided. Thus God is indivisible in all respects, as is also the human mind, not having extension or other properties of body.

INDIVISIBLES, in geometry, the elements or principles into which any body or figure may be ultimately resolved; which elements are supposed infinitely small: thus a line may be said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and then, because each of these elements is supposed indivisible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements; whence we may see that a parallelogram, prism, or cylinder, is resolvable into elements or indivisibles, all equal to each other, parallel and like to the base; a triangle into lines parallel to the base, but decreasing in arithmetical proportion; and so are the circles which constitute the parabolic conoid, and those which constitute the plane of a circle, or surface of an isosceles cone.

INDORSEMENT, in law, any thing written on the back of a deed, as a receipt for money received. See Bills of Exchange.

INDUCEMENT, in law, what is alleged as a motive or incitement to a thing, and is used specially in many cases: as, there is an inducement in actions, to a traverse in pleadings, a fact or offence committed, &c.

INDUCTION, in law, is the giving a clerk instituted to a benefice, the actual possession of the temporalities thereof, in the nature of livery of seisin. It is performed by a mandate from the bishop to the archdeacon, who commonly issues out a precept to some other clergyman to perform it for them; which being done, the clergyman who inducts him indorses a certificate of his induction on the archdeacon's mandate, and they who were present testify the same under their hands, and by this the person inducted is in full and complete possession of all the temporalities of his church.

INERTIA *of matter*, is defined by Sir Isaac Newton to be a passive principle by which bodies persist in their motion or rest, receive motion in proportion to the force impressing it, and resist as much as they are resisted.

INFAMY, which extends to forgery, perjury, gross cheats, &c. disables a man to be a witness or a juror; but a pardon of crimes restores a person's credit to make him a good evidence.

INFANCY, the first part of life. Hoffman says, that the human species are *infants* until they begin to talk, and *children* to the age of puberty.

Anatomy has discovered to us, that during infancy there is much imperfection in the human frame. Its parts are disproportioned, and its organs incapable of those functions which in future life they are destined to perform. The head is larger in proportion to the bulk of the body than that of the adult. The liver and pancreas are much larger in proportion than in advanced life; their secretions are more in quantity also. The bile is very inert; the heart is stronger and larger than in future life; the quantity of blood sent through the heart of an infant, in a given time, is also more in proportion than in adults. And although these circumstances have their important usefulness, yet the imperfection attending them subjects this age to many infirmities, injuries, and dangers from which a more perfect state is exempted. Thus infants have a larger portion of brain than adults, hence are more subject to nervous disorders; and hence the diagnostics of disease are in many respects obscure or uncertain, particularly those taken from the pulse, which from the irritability of the tender bodies of infants, is suddenly affected by a variety of accidents too numerous, and seemingly too trivial to gain our attention.

INFANT. From the observations daily made on the actions of infants, as to their arriving at discretion, the laws and customs of every country have fixed upon particular periods, on which they are presumed capable of acting with reason and discretion; in our law the full age of man or woman is twenty-one years.

The ages of male and female are different for different purposes: a male at twelve years of age may take the oath of allegiance; at fourteen is at discretion, and therefore may consent or disagree to marriage, may choose his guardian, and if his discretion is actually proved, may make his testament of his personal estate; at seventeen he may be a procurator or an executor; and at twenty-one is at his own disposal, and may alien his lands, goods, and chattels. A female at seven years of age may be betrothed or given in marriage; at nine is entitled to dower; and at twelve is of years of maturity, and therefore may consent or disagree to marriage, and if proved to have sufficient discretion may bequeath her personal estate; at fourteen is at years of legal discretion, and may choose a guardian; at seventeen may be executrix; and at twenty-one may dispose of herself and her lands.

An infant is capable of inheriting, for the law presumes him capable of property; also an infant may purchase, because it is intended for his benefit and the freehold is in him till he disagrees thereto, because an agreement is presumed, it being for his benefit. And if at his full age the infant agrees to the purchase, he cannot afterwards avoid it; but if he dies during his minority his heirs may avoid it. As to infants being witnesses, there seems to be no fixed time at which children are excluded from giving evidence; but it will depend in a great measure on the sense and understanding of the children as it shall appear on examination in court.

An infant is not bound by his contract to deliver a thing; so if one deliver goods to an infant upon a contract, &c. knowing him to be an infant, he shall not be chargeable in trover and conversion, or any other action for them; for the infant is not capable of any contract but for necessaries, therefore such delivery is a gift to the infant; but if an infant, without any contract, wilfully takes away the goods of another, trover lies against him.

An infant, knowing of a fraud, shall be as much bound as if of age.

Where goods are furnished to the son, he is himself liable if they are necessaries. If tradesmen deal with him, and he undertakes to pay them, they must resort to him for payment; but if they furnished the infant on the credit of his father, the father only is liable.

With respect to education, &c. infants may be charged, where the credit was given bona fide to them. But where the infant is under the parents' power, and living in the house with them, he shall not be liable even for necessaries.

A promissory note given by an infant for board and lodging, and for teaching him a trade, is valid, and will support an action for the money. And debts contracted during infancy are good considerations to support a promise made to them when a person is of full age; but the promise must be express.

A bond without a penalty for necessaries will bind an infant, but not a bond with a penalty. Legacies to infants cannot be paid either to them or their parents.

By the custom of London an infant unmarried, and above the age of 14, if under 21, may bind himself apprentice to a freeman of London, by indenture with proper covenants, which covenants, by the custom of London, will be as binding as if of age. An infant cannot be sued but under the protection and joining the name of his guardian; but he may sue either by his guardian, or his next friend, who is not his guardian.

INFANTRY, in military affairs, denotes the whole body of foot soldiers.

INFINITE, that which has neither beginning nor end: in which sense God alone is infinite. See GOD.

INFINITE, or **INFINITELY** *great line*, in geometry, denotes only an indefinite or indeterminate line, to which no certain bounds or limits are prescribed.

INFINITESIMALS, among mathematicians, are defined to be infinitely small quantities.

In the method of infinitesimals, the element, by which any quantity increases or decreases, is supposed to be infinitely small, and is generally expressed by two or more terms, some of which are infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity.

INFLECTION, or *point of inflection*, in the higher geometry, is the point where a curve begins to bend a contrary way.

INFLUENZA, a species of contagious catarrh, so named because it was supposed to be produced by a peculiar influence of the stars. The phenomena of contagious catarrhs have been much the same with those of the simple kind, but the disease has always been particularly remarkable for this, that it has been the most widely and generally spreading epidemic known. It has seldom appeared in any one country of Europe, without appearing successively in most of the others.

INFORMATION, in law, may be defined an accusation or complaint exhibited against a person for some criminal offence. It differs principally from an indictment in this, that an indictment is an accusation found by the oath of twelve men, but an information is only the allegation of the officer who exhibits it.

INFUSION, a method of obtaining the virtues of plants, roots, &c. by steeping them in a hot or cold liquid.

INFUSORIA, in natural history, minute simple animalcules, seldom visible to the naked eye. When water is examined with the microscope, particularly that which has long been stagnant, and has vegetable matter growing in it, or water in which vegetables have been infused, thousands of minute animals have been discovered, which have been arranged together in this order. When wheat that is richety is infused in water, small eel-shaped worms are discovered, which were the cause of the disease.

INGOT, is a small bar of metal made of a certain form and size, by casting it in hollowed iron or brass plates, called ingot-moulds. The term is chiefly applied to the small bars of gold and silver, intended either for coining, or exportation to foreign countries.

INHERITANCE, is a perpetuity in lands or tenements to a man and his heirs. Inheritances are corporeal or incorporeal. Corporeal inheritances relate to houses and lands which may be touched or handled; and incorporeal hereditaments are rights issuing out of, annexed to, or exercised with, corporeal inheritances: as advowsons, tithes, annuities, offices, commons, franchises, privileges, and services. There are several rules of inheritances of lands, according to which estates are transmitted from ancestor to heir, viz. 1. That inheritances shall lineally descend to the issue of the person last actually seised, in infinitum, but shall never lineally ascend. 2. The male issue shall be admitted before the female. 3. Where there are two or more males in equal degree the eldest only shall inherit; but the females all together. 4. The lineal descendants, in infinitum, of any person deceased shall represent their ancestor: thus, the child, grandchild, or great grandchild (either male or female,) of the eldest son, succeeds before the younger son, and so in infinitum. 5. On failure of issue of the person last seised, the inheritance shall descend to the blood of the first purchaser. 6. The collateral heir of the person last seised must be his next collateral kinsman of the whole blood. 7. In collateral inheritances the male stocks shall be preferred to the female, unless where lands are descended from a female.

INHIBITION, a writ to inhibit or forbid a judge from farther proceedings in the cause depending before him.

INJECTION, in surgery, the forcibly throwing certain liquid medicines into the body, by means of a syringe, tube, clyster-pipe, or the like.

INJECTION, *anatomical*, the filling the vessels with some coloured substance, in order to make their figures and ramifications visible.

INJUNCTION. An injunction is a prohibitory writ, restraining a person from committing or doing a thing which appears to be against equity and conscience.

An injunction is usually granted for the purpose of preserving property in dispute pending a suit; as to restrain the defendant from proceedings at the common law against the plaintiff, or from committing waste, or doing any injurious act.

Injunctions issue out of the courts of equity

is several instances. The most usual injunction is to stay proceedings at law; as, if one man brings an action at law against another, and a bill is brought to be relieved either against a penalty, or to stay proceedings at law, or some equitable circumstances, of which the party cannot have the benefit at law.

INK. Every liquor or pigment used for writing or printing, is distinguished by the name of ink. Common practice knows only black and red. Of black ink there are three principal kinds: 1. Indian ink; 2. Printers' ink; and 3. Writing ink.

The Indian ink is used in China for writing with a brush, and for painting upon the soft flexible paper of Chinese manufacture. It is ascertained, as well from experiment as from information, that the cakes of this ink are made of lamp-black and size, or animal glue, with the addition of perfumes or other substances not essential to its quality as an ink.

Good printers' ink is a black paint, smooth and uniform in its composition, of a firm black colour, and possesses a singular aptitude to adhere to paper thoroughly impregnated with moisture. Ten or twelve gallons of the oil are set over the fire in an iron pot, capable of holding at least half as much more; for the oil swells up greatly, and its boiling over into the fire would be very dangerous. When it boils it is kept stirring with an iron ladle; and if it do not itself take fire, it is kindled with a piece of flaming paper or wood; for simple boiling, without the actual ascension of the oil, does not communicate a sufficient degree of the drying quality required. The oil is suffered to burn for half an hour or more, and the flame being then extinguished by covering the vessel close, the boiling is afterwards continued with a gentle heat, till the oil appears of a proper consistence; in which state it is called varnish. It is necessary to have two kinds of this varnish, a thicker and a thinner, from the greater or less boiling, to be occasionally mixed together, as different purposes may require: that which answers well in hot weather being too thick in cold, and large characters not requiring so stiff an ink as small ones.

Lamp-black is the common material to give the black colour, of which two ounces and a half are sufficient for sixteen ounces of the varnish. Vermilion is a good red. They are ground together on a stone with a muller, in the same manner as oil paints.

The ink used by copper-plate printers differs in the oil, which is not so much boiled as to acquire the adhesive quality. This would render it less disposed to enter the cavities of the engraving, and more difficult either to be spread or wiped off. The black is likewise of a different kind. Instead of lampblack, or sublimed charcoal, the Frankfort black is used, which is a residual or denser charcoal, said to be made from vine-twigs. This is softer and less gritty than the ivory or other blacks prepared among us, and, no doubt, contains more coal than any animal residue, as all these abound with phosphate of lime.

Common ink for writing is made by adding an infusion or decoction of the nut-gall to sulphate of iron, dissolved in water. A very fine black precipitate is thrown down, the speedy subsidence of which is prevented by the addition of a proper quantity of gum-arabic.

M. Ribaucourt paid particular attention to the process for making black ink, and from his experiments he draws the following inferences:—That logwood is a useful ingredient in ink, because its colouring matter is disposed to unite with the oxide of iron, and renders it not only of a very dark colour, but less capable of change from the action of acids, or of the air. Sulphate of copper, in a certain proportion, gives depth and firmness to the colour of the ink. Gum-arabic, or any other pure gum, is of service, by retarding the precipitation of the feculæ; by preventing the ink from spreading or sinking into the paper; and by affording it a kind of compact varnish, or defence from the air when dry. Sugar appears to have some bad qualities, but is of use in giving a degree of fluidity to the ink, which permits the dose of gum to be enlarged beyond what the ink would bear without it. Water is the best solvent.

Lewis had supposed, that the defects of ink arise chiefly from a want of colouring matter. But the theory grounded on the fact discovered by M. Ribaucourt requires, that none of the principles should be in excess.

From all the foregoing considerations M. R. gives these directions for the composition of good ink: Take eight ounces of Aleppo galls (in coarse powder;) four ounces of logwood (in thin chips;) four ounces of sulphate of iron; three ounces of gum-arabic (in powder;) one ounce of sulphate of copper; and one ounce of sugar-candy. Boil the galls and logwood together in twelve pounds of water for one hour, or till half the liquid has evaporated. Strain the decoction through a hair sieve or linen cloth, and then add the other ingredients. Stir the mixture till the whole is dissolved, more especially the gum; after which, leave it to subside for twenty-four hours. Then decant the ink, and preserve it in bottles of glass or stone ware, well corked.

Many recommend, that the sulphate of iron should be calcined to whiteness. Mr. Desormeaux, jun. an ink manufacturer in Spitalfields, has given the following, in the Philosophical Magazine, as the result of much experience: —Boil four ounces of logwood about an hour in six beer quarts of water, adding boiling water from time to time; strain while hot; and when cold, add water enough to make the liquor five quarts. Into this put one pound averdup. of blue galls coarsely bruised; four ounces of sulphate of iron calcined to whiteness; three ounces of coarse brown sugar; six ounces of gum-arabic; and ¼ ounce of acetate of copper, triturated with a little of the decoction to a paste, and then thoroughly mixed with the rest. This is to be kept in a bottle uncorked about a fortnight, shaking it twice a-day, after which it may be poured from the dregs, and corked up for use.

Inks of other colours may be made from a strong decoction of the ingredients used in dyeing, mixed with a little alum and gum-arabic. For example, a strong decoction of Brazil wood, with as much alum as it can dissolve, and a little gum, forms a good red ink. These processes consist in forming a lake, and retarding its precipitation by the gum. See Lake.

Among the amusing experiments of the art of chemistry, the exhibition of sympathetic inks holds a distinguished place. With these the writing is invisible, until some re-agent gives it

opacity. We shall here mention a few out of the great number, that a slight acquaintance with chemistry may suggest to the student. 1. If a weak infusion of galls be used, the writing will be invisible till the paper be moistened with a weak solution of sulphate of iron. It then becomes black, because these ingredients form ink. 2. If paper be soaked in a weak infusion of galls, and dried, a pen dipped in the solution of sulphate of iron will write black on that paper, but colourless on any other paper. 3. The diluted solutions of gold and silver remain colourless upon the paper, till exposed to the sun's light, which gives a dark colour to the oxides, and renders them visible. 4. Most of the acids, or saline solutions, being diluted, and used to write with, become visible by heating before the fire, which concentrates them, and assists their action on the paper. 5. Diluted prussiate of potash affords blue letters when wetted with the solution of sulphate of iron. 6. The solution of cobalt in aqua regia, when diluted, affords an ink which becomes green when held to the fire, but disappears again when suffered to cool. This has been used in fanciful drawings of trees, the green leaves of which appear when warm, and vanish again by cold. If the heat be continued too long after the letters appear, it renders them permanent. 7. If oxide of cobalt be dissolved in acetic acid, and a little nitre added, the solution will exhibit a pale rose colour when heated, which disappears on cooling. 8. A solution of equal parts of sulphate of copper and muriate of ammonia, gives a yellow colour when heated, that disappears when cold.

Ink, *removing stains of.* The stains of ink on cloth, paper, or wood, may be removed by almost all acids; but those acids are to be preferred which are least likely to injure the texture of the stained substance. The muriatic acid, diluted with five or six times its weight of water, may be applied to the spot, and, after a minute or two, may be washed off, repeating the application as often as may be found necessary. But the vegetable acids are attended with less risk, and are equally effectual. A solution of the oxalic, citric (acid of lemons,) or tartareous acids, in water, may be applied to the most delicate fabrics without any danger of injuring them; and the same solutions will discharge writing, but not printing-ink. Hence they may be employed in cleaning books which have been defaced by writing on the margin, without impairing the text. Lemon-juice, and the juice of sorrel, will also remove ink-stains, but not so easily as the concrete acid of lemons, or citric acid.

INN, a place appointed for the entertainment and relief of travellers. If one who keeps a common inn refuse either to receive a traveller as a guest into his house, or to find him victuals or lodging, upon his tendering a reasonable price for them, he is not only liable to render the damages for the injury in an action on the case, at the suit of the party grieved, but also may be indicted and fined at the suit of the king. In return for such responsibility, the law allows him to retain the horse of his guest until paid for his keep; but he cannot retain such horse for the bill of the owner, although he may retain his goods for such bill; neither can he detain one horse for the food of another. An innkeeper, however, is not bound to receive the horse unless the master lodge there also; Neither is a landlord bound to furnish provisions, unless paid beforehand. If an innkeeper make out unreasonable bills, he may be indicted for extortion; and if either he or any of his servants knowingly sell bad wine, or bad provisions, they will be responsible in an action of deceit. Keeping an inn is not a trading to make a man a bankrupt; but where an innkeeper is a chapman also, and buys and sells, he may on that account be a bankrupt. Innkeepers are clearly chargeable for the goods of guests stolen or lost out of their inns, and this without any contract or agreement for that purpose. But if a person come to an innkeeper, and desire to be entertained by him, which the innkeeper refuses because in fact his house is already full; whereupon the party says, he will shift among the rest of his guests, and there he is robbed, the host shall not be charged. If a man come to a common inn to harbour, and desire that his horse may be put to grass, and the host put him to grass accordingly, and the horse is stolen, the host shall not be charged. Innkeepers may detain the person of the guest who eats till payment. By the custom of London and Exeter, if a man commit a horse to an hostler, and he eat out the price of his head, the hostler may sell him upon the reasonable appraisement of four of his neighbours; yet he cannot justify the taking him to himself at the price it was appraised at.

Inns *of court* are so called, because the students therein study the law, to enable them to practise in the courts at Westminster or elsewhere; and also because they use all other gentle exercises, as may render them better qualified to serve the king in his court.

INNATE *ideas*, those supposed to be stamped on the mind from the first moment of its existence, and which it constantly brings into the world with it: a doctrine which Mr. Locke has abundantly refuted.

INNOMINATA *ossa*, in anatomy, three bones, which compose the extreme part of the trunk of a human body.

INNUENDO, is a word used in declarations and law pleadings, to ascertain a person or thing which was named before; as to say he (innuendo the plaintiff) did so and so, when there was mention before of another person. Innuendo may serve for an explanation, where there is precedent matter, but never for a new charge; it may apply what is already expressed, but cannot add or enlarge the importance of it.

INOCULATION, in medicine, the art of transplanting a distemper from one subject to another, by incision, particularly used for ingrafting the small-pox. See Vaccination.

Inoculation. See Budding.

INORDINATE *proportion*, is where there are three magnitudes in one rank, and three others proportional to them in another, and you compare them in a different order. Thus suppose the numbers in one rank to be 2, 3, 9; and those of the other rank 8, 24, 36; which are compared in a different order, *viz.* 2 : 3 :: 24 : 36; and 3 : 9 :: 8 : 24. Then rejecting the mean terms of each rank, you conclude 2 : 9 :: 8 : 36.

INQUEST, in law, an inquisition by jurors, or a jury, which is the most usual trial of all causes, both civil and criminal, within this realm.

INQUISITION, in law, a manner of pro-

ceeding by way of search or examination used on the king's behalf, in cases of outlawry, treason, felony, self-murder, &c. to discover lands, goods, and the like, forfeited to the crown. Inquisition is also had upon extents of lands, tenements, &c. writs of elegit, and where judgment being had by default, damages and costs are recovered.

Inquisition, in the church of Rome, a tribunal in several Roman catholic countries, erected by the popes for the examination and punishment of heretics.

INROLLMENT, in law, is the registering, recording, or entering in the rolls of the Chancery, King's Bench, Common Pleas, or Exchequer, or by the clerk of the peace in the records of the quarter sessions, of any lawful act; a statute or recognizance acknowledged, a deed of bargain and sale of lands, and the like. By statute 27, Henry VIII. c. 16, no lands shall pass, whereby any estate of inheritance or freehold shall take effect, or any use thereof be made, by reason only of any bargain and sale thereof, except the bargain and sale be made by writing indented, sealed, and within six months inrolled in one of the king's courts of record at Westminster; or else within the county where the lands lie, before the clerk of the peace, and one or more justices. But by 5 Elizabeth, c. 26, in the counties palatine, they may be inrolled at the respective courts there, or at the assizes. Every deed before it is inrolled is to be acknowledged to be the deed of a party, before a master of chancery, or a judge of the court wherein it is inrolled, which is the officer's warrant for inrolling it; and the inrollment of a deed, if it be acknowledged by the grantor, it will be a good proof of the deed itself upon trial. But a deed may be inrolled without the examination of the party himself; for it is sufficient if oath be made of the execution.

INSCRIBED, in geometry. A figure is said to be inscribed in another when all its angles touch the sides or planes of the other figure.

INSECTS. See Entomology.

INSOLUBILITY, in chemistry. The insolubility of a substance in a fluid, which is the medium of chemical action, has an influence on that action somewhat similar to that of cohesion, and is nothing but a modification of it, in relation to the fluid in which it is exerted.

INSOLVENT *debtors.* Insolvent acts are statutes passed for the purpose of releasing from prison, and sometimes from their debts, persons whose transactions have not been of such a nature as would subject them to the bankrupt laws. Their discharge is usually from all suits and imprisonment, upon delivering up all their estates and effects, real and personal, for the benefit of their creditors.

INSPIRATION, among divines, &c. implies the conveying of certain extraordinary notices or motions into the mind; or it denotes any supernatural influence of God upon the mind of a rational creature, wherby he is formed to any degree of intellectual improvements, to which he could not have attained in his present circumstances, in a natural way. Thus the prophets are said to have spoken by divine inspiration.

Some writers reduce the inspiration of the Scriptures to a particular care of Providence, which prevented any thing they had said from failing or coming to nought; maintaining, that they never were really inspired either with knowledge or expression. According to others, inspiration is nothing more than a direction of the Holy Spirit, which never permitted the sacred writers to be mistaken. It is a common opinion, that the inspiration of the Holy Spirit regards only the matter, not the style or words.

There is scarcely any subject connected with theology that has called forth a greater display of talent than the vindication of the divine authority of the Scriptures, and the truth of the Christian religion. It is, however, an incontrovertible fact, that the ablest of such performances are more adapted to silence, than to satisfy, the mind of even an ingenuous inquirer. This painful truth is widely felt; and infidelity has recently taken a most unprecedented and unblushing advantage of it in this country. Yet however much such an event is to be deplored, we sincerely congratulate the friends of Christianity, on an acquisition of uncommon importance, which they have gained in the appearance of a volume from the pen of the Rev. Samuel Noble, of London, on the Plenary Inspiration of the Scriptures. This invaluable work contains six lectures delivered at Albion Hall, London Wall. The ground chosen by the Lecturer is entirely new; and the luminous and conclusive manner in which he pursues his argument, is such as to throw a radiance of celestial light around the most obscure portions of the sacred volume. The reader is furnished with a principle of interpretation which is at once of undeviating certainty, and universal application; and before which, the most ingenious and formidable objections that ever issued from the schools of infidelity, flee, like the shades of night, at the approach of the orb of day.

The rule to which we refer is afforded in the mutual relation which exists by creation between things natural or material, spiritual, or moral and divine; which is such that the lower order of objects answers to the higher, as certainly and immutably, as the reflection in a mirror answers to the substance producing it.

INSTALLMENT, the instating or establishing a person in some dignity. This word is chiefly used for the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his stall, or other proper seat in the cathedral to which he belongs. It is also used for the ceremony whereby the knights of the garter are placed in their rank in the chapel of St. George at Windsor, and on many other like occasions. It is sometimes termed installation.

INSTANT, such a part of duration wherein we perceive no succession; or it is that which takes up the time only of one idea in our minds.

INSTINCT, an appellation given to the sagacity and natural inclinations of brutes, which supplies the place of reason in mankind.

INSTITUTES, in literary history, a book containing the elements of the Roman law, and constitutes the last part of the civil law. The Institutes are divided into four books, and contain an abridgment of the whole body of the civil law, being designed for the use of students.

INSTITUTION, to a benefice, is that whereby the ordinary commits the cure of souls to the parson presented, as by induction he ob-

tains a temporal right to the profits of the living. Previous to the institution, the oath against simony, the oaths of allegiance and supremacy, are to be taken; and if it be a vicarage, the oath of residence. They are also to subscribe the thirty-nine articles, and the articles concerning the king's supremacy, and the book of common prayer.

INSULATED, in electricity, a term applied to bodies that are supported by electrics, or non-conductors, so that their communication with the earth, by conducting substances, is interrupted.

INSURANCE, or **Assurance**, in law and commerce, a contract or agreement whereby one or more persons, called insurers, assurers, &c. oblige themselves to answer for the loss of a ship, house, goods, &c. in consideration of a premium paid by the proprietors of the things insured.

INTAGLIOS, precious stones on which are engraven the heads of great men, inscriptions, and the like; such as we frequently see set in rings, seals, &c.

INTEGER, in arithmetic, a whole number, in contradistinction to a fraction.

INTEGRAL, or *integrant*, in philosophy, appellations given to parts of bodies which are of a similar nature with the whole: thus filings of iron have the same nature and properties as bars of iron.

INTEGRAL *calculus*. See **Calculus**.

INTEGUMENTS, in physiology, denote the common coverings which invest the body, as the cutis, &c. The common integuments are the skin, with the fat and cellular membrane adhering to it. The term integument is also extended to the particular membranes which invest certain parts of the body, as the coats or tunics of the eye.

INTEREST, is an allowance paid by the borrower to the lenders of money, for the use of it for a certain time. The sum lent is called the *principal*; the sum paid by the borrower, the interest; and both conjoined, the *amount*. If interest, after it becomes due, be incorporated with the principal, and interest be afterwards charged on the successive amounts, it gives rise to what is denominated *compound interest*, to distinguish it from simple interest, in which the interest, though foreborn, is charged only on the sum originally lent.

Simple Interest.

Let p denote principal, r the interest of £1. for one year, t the number of years the interest is due, and a the amount for the same time; then it is obvious that $a = p + r\,t$, or $a = p\,(1 + r\,t.)$ $p = \frac{a}{1 + r\,t}$, $r = \frac{a - p}{p\,t.}$, $t = \frac{a - p}{p\,r}$. Since r is the rate of £1. for one year, $\frac{r}{305}$ will be the rate for a single day; and therefore if d be the number of days, $\frac{d\,r}{305}$ will be the interest of £1. for the same time. If the rate be 5 *per cent.* or $\frac{1}{20}$, the interest of p pounds, for d days, will become $\frac{\frac{1}{20}\,p\,d}{365}$, or $\frac{p\,d}{7300}$.

Example:—What is the interest of £456, for 85 days at 5 *per cent.?*

$$\text{Interest} = \frac{456 \times 85}{7300} = £5:6:2\tfrac{1}{4}.$$

Compound Interest.

Let r now represent the amount of one pound in one year, that is, principal and interest; let n = the number of years; p = the principal; a = the amount. Then,

$1 : r :: r : r^2$ the amount of 1*l.* in 2 years,
$1 : r :: r^2 : r^3$ the amount of 1*l.* in 3 years,
$1 : r :: r^3 : r^4$ the amount of 1*l.* in 4 years, &c.

Whence it appears, that r raised to the power whose exponent is the given number of years, or r^n, will be the amount of 1*l.* in those years; and as

$$1l. : r^n :: p : a$$

from which the following theorems are easily deduced, viz. If the principal, time, and rate of interest are given, to find the amount:

Theo. 1. $p \times r^n = a$

If the amount, time, and rate are given, to find the principal?

Theo. 2. $\frac{a}{r^n} = p$

If the principal, amount, and time are given, to find the rate:

Theo. 3. $\sqrt[n]{\frac{a}{p}} = r$

If the principal, amount, and rate are given, to find the time:

Theo. 4. $\left\{ \frac{a}{p} = r^n \right.$, therefore $\frac{a}{p}$ being divided by r till nothing remains, the number of divisions will be n.

INTERJECTION, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind.

INTERLOCUTORY *order*, in law, an order that does not decide the cause, but only some matter incident to it, which happens between the beginning and end of a cause.

INTERLUDE, an entertainment exhibited on the stage, between the acts of a play, for the purpose of allowing the performers time to rest, the scenes to be shifted, &c.

INTERMITTENT, or **Intermitting Fevers**. See **Medicine**.

INTERNAL, in general, signifies whatever is within a thing.

Euclid proves that the sum of the three internal angles of every triangle is equal to two right angles; whence he deduces several useful corollaries. He likewise adduces, from the same proposition, this theorem, viz. that the sum of the angles of every rectilinear figure, is equal to twice as many right angles, as the figure hath sides, excepting or subtracting four.

INTERPOLATION, among critics, denotes a spurious passage, inserted into the writings of some ancient author. One great rule with regard to the expunging interpolations, is, that the restitution be perfectly agreeable to the rest of the work

INTERROGATION, or *point of* **Interrogation**, in grammar, a character of this form (?) serving to denote a question.

INTERSECTION, in the mathematics, signifies the cutting of one line or plane by another: thus we say, that the mutual intersection of two planes is a right line.

INTERVAL, in music, the difference between two sounds, in respect of acute and grave; or that imaginary space terminated

by two sounds, differing in acuteness or gravity.

Intervals are distinguished into simple and compound. A simple interval is without parts or divisions. Such are the octave, and all that are within it; as the second, third, fourth, fifth, sixth, and seventh, with their varieties. A compound interval consists of several lesser intervals; such are all those which are greater than the octave, as the ninth, tenth, eleventh, twelfth, &c. with their varieties.

INTESTATES. There are two kinds of intestates; one that makes no will at all; and another that makes a will, and nominates executors, but they refuse. The ordinary by special acts of parliament is required to give administration of the effects of the deceased to the widow or next of kin, who shall first pay the debts of the deceased, and then distribute the surplus among the kindred, in the proportions directed by 22 and 23 Car. II. c. 10.

INTESTINA, in natural history, the first of the five orders of the class vermes, in the Linnæan system. This order is described as of a formation the most simple, being naked animals without limbs. They live, some of them within other animals, some in waters, and a few in the earth. They are distinguished from the Mollusca, by the want of moveable appendages, or tentacula.

INTORSION, in botany, a term used to denote the bending of any of the parts of a plant towards one side. This admits of certain distinctions. 1. Twining stems, which bend towards the left, as in hops, honey-suckle, &c.; but in the kidney-bean, convolvolus, &c. they bend to the right. 2. Twining tendrils, which bend to the right and back again; of this kind are the tendrils of most of the pea-bloom or leguminous tribe of plants. 3. Twisted flowers, in the periwinkle, the petals bend to the left; the pointal in the viscous campion is twisted to the left, as the seed-bud is in the screw-tree. In oats, the beard which terminates the husk is twisted like a rope. This species of contorsion being affected by the moisture or dryness of the atmosphere, is denominated by Linnæus, "intorsio hygrometrica."

INTRINSIC, a term applied to the inner, real, and genuine values, properties, &c. of any thing, in opposition to their extrinsic or apparent values, &c.

INTUITION, the act whereby the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other; in which case, the mind perceives the truth as the eye doth the light, only by being directed towards it. Thus the mind perceives that white is not black, that three are more than two, and equal to one and two. This part of knowledge, says Mr. Locke, is irresistible; and like the sunshine, forces itself immediately to be perceived as soon as ever the mind turns its view that way. It is on this intuition that all the certainty and evidence of our other knowledge depend; this certainty every one finds to be so great, that he cannot imagine, and therefore cannot require, a greater.

INVECTED, in heraldry, denotes a thing fluted or furrowed. Invected is the reverse of ingrailed, in which the points are turned outward to the field, whereas in invected they are turned inward to the ordinary, and the small semicircles outward to the field.

INVECTIVE, in rhetoric, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the person reproved: whereas the invective is the work of an enemy, and entirely designed to vex and give uneasiness to the person against whom it is directed.

INVOICE, an account in writing, of the particulars of merchandize, with their value, custom, charges, &c. transmitted by one merchant to another in a distant country. One copy of every invoice is to be inserted, verbatim, in the invoice-book, for the merchant's private use; and another copy must, immediately upon shipping off the goods, be dispatched by post, or otherwise, to the correspondent. An invoice has generally a letter of advice subjoined.

IODINE. This term is of Greek etymology, and literally signifies a *violet colour*. It has been recently introduced into the language of chemistry to denote a peculiar and hitherto undecompounded principle recently discovered.

Iodine was accidentally discovered in 1812, by M. De Courtois, a manufacturer of saltpetre at Paris. In his processes for procuring soda from the ashes of sea-weeds, he found the metallic vessels much corroded; and in searching for the cause of the corrosion, he made this important discovery.

Iodine derived its first illustration from MM. Clement and Desormes. In their memoir, read at a meeting of the Institute, these able chemists described its principal properties. They stated its sp. gr. to be about 4: that it becomes a violet-coloured gas, at a temperature below that of boiling water; that it combines with the metals, and with phosphorus and sulphur, and likewise with the alkalis and metallic oxides; that it forms a detonating compound with ammonia; that it is soluble in alcohol, and still more soluble in ether; and that by its action upon phosphorus, and upon hydrogen, a substance having the characters of muriatic acid is formed.

Iodine is a solid, of a greyish-black colour and metallic lustre. It is often in scales similar to those of micaceous iron ore, sometimes in rhomboidal plates, very large and very brilliant. It has been obtained in elongated octohedrons, nearly half an inch in length; the axes of which were shewn by Dr. Wollaston to be to each other, as the numbers 2, 3, and 4, at least so nearly, that in a body so volatile, it is scarcely possible to detect an error in this estimate, by the reflective goniometer. Its fracture is lamellated, and it is soft and friable to the touch. Its taste is very acrid, though it be very sparingly soluble in water. It is a deadly poison. It gives a deep brown stain to the skin, which soon vanishes by evaporation. In odour, and power of destroying vegetable colours, it resembles very dilute aqueous chlorine. The sp. gr. of iodine at 62½° is 4.948. It dissolves in 7000 parts of water. The solution is of an orange-yellow colour.

Iodine is incombustible, but with azote it forms a curious detonating compound; and in combining with several bodies, the intensity of mutual action is such as to produce the phenomena of combustion.

Iodine forms with sulphur a feeble compound, of a greyish-black colour, radiated like sulphuret of antomony. When it is distilled with water, iodine seperate.

Iodine and phosphorus combine with great rapidity at common temperatures, producing heat without light. From the presence of a little moisture, small quantities of hydriodic acid gas are exhaled. Oxygen expels iodine from both sulphur and phosphorus. "Hydrogen, whether dry or moist, did not seem," says M. Gay Lussac, " to have any action on iodine at the ordinary temperature; but if, as was done by M. Clement in an experiment at which I was present, we expose a mixture of hydrogen and iodine to a red heat in a tube, they unite together, and hydriodic acid is produced, which gives a reddish brown colour to water." Sir H. Davy threw the violet-coloured gas upon the flame of hydrogen, when it seemed to support its combustion. He also formed a compound of iodine with hydrogen, by heating to redness the two bodies in a glass tube.

Charcoal has no action upon iodine, either at a high or low temperature. Several of the common metals, on the contrary, as zinc, iron, tin, mercury, attack it readily, even at a low temperature, provided they be in a divided state. Though these combinations take place rapidly, they produce but little heat, and but rarely any light. The compound of iodine and zinc, or iodide of zinc, is white. It melts readily. Iron is acted on by iodine in the same way as zinc; and a brown iodide results, which is fusible at a red heat. It dissolves in water, forming a light green solution, like that of muriate of iron. Iodine and tin act very well on each other, in water of the temperature of 212°. By employing an excess of tin, we may obtain pure hydriodic acid, or at least an acid containing only traces of the metal. Antimony presents, with iodine, the same phenomena as tin; so that we might employ either for the preparation of hyriodic acid, if we were not acquainted with a preferable method. The iodides of lead, copper, bismuth, silver, and mercury, are insoluble in water, while the iodides of the very oxidizable metals are soluble in that liquid. If we mix a hydriodate with the metallic solutions, all the metals which do not decompose water will give precipitates, while those which decompose that liquid will give none. This is at least the case with the above mentioned metals. Dr. Coindet of Geneva has recommended the use of iodine in the form of tincture, and also hydriodate of potash or soda, as an efficacious remedy for the cure of glandular swellings of the goitrous and scrophulous kind.

JOINERY, the art of working in wood, or of fitting various pieces of timber together. It differs from the art of the carpenter, inasmuch as the joiner is employed chiefly in the inside work of a house, but the carpenter does the rough work, which, in general, requires more strength and less skill.

JOINT, *universal*, is an invention adapted to all kinds of motion and flexures; of this kind is the ball and socket joint, used in the construction of the theodolite, spirit-level, &c.

JOINT *actions*, in personal actions, several wrongs may be joined in one writ; but actions founded upon a tort and a contract cannot be joined, for they require different pleas and different process.

JOINT *lives*: lease for years to husband and wife, if they or any issue of their bodies should so long live, has been adjudged so long as either the husband, wife, or any of their issue should live; and not only so long as the husband and wife, &c. should jointly live.

JOINT *stock companies*, are commercial associations, having a stock consisting of many shares; in such associations the share-holders gain or lose according to the proportion in which they hold their shares. These associations are, in general, of but little advantage to individuals; those who profit most by them are the persons who are paid for managing them.

The most celebrated instances of companies of this description on record are those of the Mississipi scheme in France, and the South Sea scheme in England. The failure of these romantic speculations drew down ruin on many thousands, and the country in general was convulsed by the injuries sustained; yet, with such direful proofs of the certain consequences of all such Utopian speculations before their eyes, the people of England are, at the present hour, the dupes of a mania which unless the wisdom of the legislature interfere, must spread desolation to a far more fearful extent than ever was experienced from the bursting of the South Sea bubble.

JOINT *tenants*, are those that come to, and hold lands or tenements by one title, *pro indiviso*, or without partition. These are distinguished from sole or several tenants, from parceners, and from tenants in common; and they must jointly implead, and jointly be impleaded by others, which properly is common between them and co-parceners; but joint tenants have a sole quality of survivorship, which co-parceners have not. The creation of an estate in joint tenancy depends on the wording of the deed or devise, by which tenant claims title, and cannot arise by act of law. If any estate be given to a plurality of persons, without adding any restrictive, exclusive, or explanatory words, this makes them immediately joint tenants in fee of the lands. If there be two joint tenants, and one release the other, this passes a fee without the word heirs, because it refers to the whole fee, but the tenants in common cannot release each other, for a release supposes the party to have the thing in demand; but tenants in common have several distinct freeholds, which they cannot transfer otherwise than as persons who are sole seized

At common law, joint tenants in common were not compellable to make partition; except by the custom of some cities and boroughs. But now joint tenants may make partition; the one party may compel the other to make partition which must be by deed. that is to say, all the parties must by deed actually convey and assure to each other the several estates, which they are to take and enjoy severally and separately. Joint tenants must jointly implead, and be jointly impleaded with others. If one joint tenant refuse to join in an action, he may be summoned and severed; but if the person severed die, the writ abates in real actions, but not in personal and mixed actions.

IOLITE. Prismato-rhomboidal quartz of Mohs. Colour intermediate between violet-blue and blackish-blue. When viewed in the

direction of the axis of the crystals, the colour is dark indigo-blue; but perpendicular to the axis of the crystals, pale brownish-yellow. Massive, disseminated, rarely crystallized in six-sided prisms. Lustre vitreous. Fracture small grained uneven. Refracts double. Sp. gr. 2.5 to 2.6. Easily frangible. Its constituents are, silica 43.6, alumina 37.6, magnesia 9.7, potash 1, oxide of iron 4.5, oxide of manganese a trace.—*Gmelin.* It occurs in primitive rocks at Orijarvi, near Abo in Finland. It is cut and polished for a gem.

JOINTURE. A jointure, strictly speaking, signifies a joint estate, limited to both husband and wife; but in common acceptation, it extends also to a sole estate, limited to the wife only, and may be thus defined, viz. a competent livelihood of freehold for the wife of lands and tenements, to take effect, in profit or possession, presently after the death of the husband; for the life of the wife at least.

To the making of a perfect jointure six things are observed. 1. Her jointure is to take effect presently after her husband's decease. 2. It must be for the term of her own life, or greater estate. 3. It should be made to herself. 4. It must be made in satisfaction of her whole dower, and not of part of her dower. 5. It must either be expressed or averred to be in satisfaction of her dower. 6. It should be made during the coverture.

JOISTS, in architecture, those pieces of timber framed into the girders and summers, on which the boards of the floor are laid. See ARCHITECTURE and BUILDING.

IONIC *order*, the third of the five orders of architecture, being a kind of mean between the robust and delicate orders. See ARCHITECTURE.

IONIC *dialect* in grammar, a manner of speaking peculiar to the people of Ionia. The Ionians generally changed the ω into η, as σοφια into σοφιη; they put the η and ι for ε, and αιη for η, as αγγηϊον for αγγεῖον: αναγκαιη for αναγκη: they also change α and ει into ηϊ, αυ into ωϋ, ει into εα and εε, ευ into ω and ηϋ, and εο into ευ.

JOURNAL, a day-book, register, or an account of daily transactions. See Art. BOOK-KEEPING

JOURNEYMAN, properly one who works by the day only; but it is now used for any one who has served an apprenticeship, and who works under a master, either by the day, the year, or the piece.

JOY, one of the most powerful mental emotions accompanied with an extraordinary degree of animation and pleasure. The effect of joy, if not too violent, invigorates the whole animal frame. But sudden and excessive joy is often as injurious as the operation of either grief or terror, and there are a thousand instances on record, in which the precipitate communication of unexpected good news has proved fatal.

IRIDIUM, a new metal lately discovered by Mr. Tennant in the ore of platina. It is of a white colour, and perfectly infusible. It does not combine with sulphur or arsenic. Lead unites with it, but may be separated by cupellation. Copper, silver, and gold, are found to combine with it. See CHEMISTRY.

IRIS, in anatomy, a striped, variegated circle round the pupil of the eye; it is formed of a duplicature of the uvea. See ANATOMY.

IRIS, the flower-de-luce, or flag-flower, &c.; a genus of the monogynia order in the triandria class of plants; and in the natural method ranking under the sixth order, ensatæ. The corolla is divided into six parts; the petals alternately reflexed; the stigmata resembling petals.

There are fifty species, all herbaceous flowering perennials, both of the fibrous, tuberous, and bulbous-rooted kind, producing thick annual stalks from three or four inches to a yard high, terminated by large hexapetalous flowers, having three of the petals reflexed quite back, and three erect; most of which are very ornamental, appearing in May, June, and July.

IRIS also signifies those changeable colours which appear in the glasses of telescopes, microscopes, &c. and which are so called from their resembling the colours of the rainbow.

IRON, the most abundant and the most useful of all metals, was neither known so early, nor wrought so easily as gold, silver, and copper. Iron is of a bluish white colour; and when polished has a great deal of brilliancy. It has a styptic taste, and emits a smell when rubbed. This metal is easily oxidized. A piece of iron wire, immersed in a jar of oxygen gas, being ignited at one end, will be entirely consumed by the successive combustion of its parts. It requires a very intense heat to fuse it; on which account it can only be brought into the shape of tools and utensils by hammering. This high degree of infusibility would deprive it of the most valuable property of metals, namely, the uniting of smaller masses into one, if it did not possess another singular and advantageous property, which is found in no other metal except platina, namely, that of welding. In a white heat, iron appears as if covered with a kind of varnish, and in this state if two pieces be applied together, they will adhere, and may be perfectly united by forging.

When iron is exposed to the action of moist air or water, it acquires weight by gradual oxidation, and hydrogen gas escapes: this is a very slow operation. But if the steam of water be made to pass through a red-hot gun barrel, or through an ignited copper or glass-tube, containing iron wire, the iron becomes converted into an oxide, while hydrogen gas passes out at the other end of the barrel. By the action of stronger heat this becomes a reddish-brown oxide. Sulphur combines very readily with iron. A mixture of iron filings and flowers of sulphur being moistened, or made into a paste with water, becomes hot, swells, adheres together, breaks, and emits watery vapours of an hepatic smell. If the mixture be considerable in quantity, as for example, one hundred pounds, it takes fire in twenty or thirty hours, as soon as the aqueous vapours cease. By fusion with iron, sulphur produces a compound of the same nature as the pyrites, and exhibits the same radiated structure when broken. If a bar of iron be heated to whiteness, and then touched with a roll of sulphur, the two substances combine, and drop down together in a fluid state. Phosphorus may be combined with iron by adding it, cut into small pieces, to fine iron wire heated moderately red in a crucible; or by fusing six parts of iron clippings, with six of glacial phosphoric acid, and one of charcoal powder. This phosphuret is magnetic. Iron

unites with gold, silver, and platina. When heated to a white heat, and plunged in mercury, it becomes covered with a coating of that metal.

There are a great many varieties of iron, which are distinguished by particular names; but all of them may be reduced under one or other of the three following classes: cast iron; wrought or soft iron; and steel. Cast, or pig iron, is the name of the metal when first extracted from its ores. The ores from which iron is usually obtained are composed of oxide of iron and clay. The object of the manufacturer is to reduce the oxide to the metallic state, and to separate all the clay with which it is combined. These two objects are accomplished at once, by mixing the ore reduced to small pieces with a certain portion of limestone and of charcoal, and subjecting the whole to a very violent heat in furnaces constructed for the purpose. The charcoal absorbs the oxygen of the oxide, flies off in the state of carbonic acid gas, and leaves the iron in the metallic state; the lime combines with the clay, and both together run into fusion, and form a kind of fluid glass; the iron is also melted by the violence of the heat, and being heavier than the glass, falls down, and is collected at the bottom of the furnace. A hole at the lower part of the furnace is now opened, and the iron allowed to flow out into moulds prepared for its reception.

To convert it into wrought iron, it is put into a furnace, and kept melted, by means of the flame of the combustibles, which is made to play upon its surface. While melted, it is constantly stirred by a workman, that every part of it may be exposed to the air. In about an hour the hottest part of the mass begins to heave and swell, and to emit a lambent blue flame. This continues nearly an hour; and by that time the conversion is completed. As the process advances, the iron gradually acquires more consistency; and at last, notwithstanding the continuance of the heat, it congeals all together. It is then taken while hot, and hammered violently, by means of a heavy hammer driven by machinery. This not only makes the particles of iron approach nearer each other, but drives away several impurities which would otherwise continue attached to the iron.

If the purest malleable iron be bedded in pounded charcoal, in a covered crucible, and kept for a certain number of hours in a strong red heat, it is found, that by this operation, which is called cementation, the iron has gained a small addition of weight, amounting to about the hundred and fiftieth, or the two-hundredth part; and is remarkably changed in its properties. It is much more brittle and fusible than before. Its surface is commonly blistered when it comes out of the crucible; and it requires to be forged, to bring its parts together into a firm and continuous state. This cemented iron is called steel. It may be welded like bar iron, if it has not been fused, or over-cemented; but its most useful and advantageous property is that of becoming extremely hard when ignited and plunged into cold water.

The usual time required for the cementation of steel is from six to ten hours. If the cementation be continued too long, the steel becomes porous, brittle, of a darker fracture, more fusible, and incapable of being forged or welded. On the contrary, steel cemented with earthy infusible powders, is gradually reduced to the state of forged iron again. The texture of steel is rendered more uniform by fusing it before it is made into bars: this is called cast steel; and is rather more difficultly wrought than common steel, because it is more fusible, and is dispersed under the hammer if heated to a white heat. Iron is one of the most valuable articles of the materia medica. The protoxide acts as a genial stimulant and tonic, in all cases of chronic debility not connected with organic congestion or inflammation. It is peculiarly efficacious in chlorosis. It appears that the peroxide and its combinations are almost uniformly irritating, causing heart-burn, febrile heat, and quickness of pulse. Many chalybeate mineral waters contain an exceedingly minute quantity of protocarbonate of iron, and yet exercise an astonishing power in recruiting the exhausted frame. Their virtue appears to be derived simply from the metal being oxidized to a minimum, and diffused by the agency of a mild acid through a great body of water, in which state it is rapidly taken up by the lacteals, and speedily imparts a ruddy hue to the wan countenance. These qualities may be imitated exactly, by dissolving 3 grains of sulphate of iron, and 60 of bicarbonate of potash, in a quart of cool water, with agitation in a close vessel.

IRRATIONAL, an appellation given to surd numbers and quantities. See ALGEBRA.

IRREGULAR, in grammar, such inflections of words as vary from the general rules; thus we say, irregular nouns, irregular verbs.

IRRIGATION. See AGRICULTURE.

ISATIS, *woad;* a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, the siliquosa. The siliqua is lanceolated, unilocular, monospermous, bivalved, and deciduous; the valves navicular or canoe-shaped. There are four species; but the only one worthy of notice is the tinctoria, or common woad, which is cultivated in several parts of Britain for the purposes of dyeing, being used as a foundation for many of the dark colours. See DYEING.

ISERINE, in mineralogy, a species of the menachine genus: it is of an iron-black, inclining a little to the brownest black; it occurs in small, obtuse, angular grains, and in rolled pieces, with a rough glimmering surface. Internally it is glittering, and its lustre is semi-metallic. Specific gravity, 4.6. It melts into a blackish-brown coloured glass.

ISINGLASS. This substance is almost wholly gelatin; 100 grains of good dry isinglass containing rather more than 98 of matter soluble in water.

Isinglass is made from certain fish found in the Danube, and the rivers of Muscovy. Willoughby and others inform us, that it is made of the sound of the Beluga; and Neumann, that it is made of the Huso Germanorum, and other fish, which he has frequently seen sold in the public markets of Vienna. Mr. Jackson remarks, that the sounds of cod, properly prepared, afford this substance; and that the lakes of America abound with fish from which the very finest sort may be obtained.

Isinglass receives its different shapes in the following manner:—The parts of which it is composed, particularly the sounds, are taken from the fish while sweet and fresh, slit open,

washed from their slimy *sordes*, divested of a very thin membrane which envelopes the sound, and then exposed to stiffen a little in the air. In this state they are formed into rolls about the thickness of a finger, and in length according to the intended size of the staple; a thin membrane is generally selected for the centre of the roll, round which the rest are folded alternately, and about half an inch of each extremity of the roll is turned inwards. Isinglass is best made in the summer, as frost gives it a disagreeable colour, deprives it of weight, and impairs its gelatinous principles. Isinglass boiled in milk forms a mild nutritious jelly, and is thus sometimes employed medicinally. This, when flavoured by the art of the cook, is the blanc-manger of our tables. A solution of isinglass in water, with a very small proportion of some balsam, spread on black silk, is the court-plaster of the shops.

ISIS, *coral*, in natural history, a genus of the vermes zoophyta class and order, of which there are six species. See CORALLINES.

ISLAND, or ICELAND, *crystal*, a body famous among the writers of optics, for its property of a double refraction; but improperly called by that name, as it has none of the distinguishing characters of crystal, and is plainly a body of another class. Dr. Hill has reduced it to its proper class, and determined it to be of a genus of spars. It is always found in form of an oblique parallelopiped, with six sides, and is found of various sizes, from a quarter of an inch to three inches or more in diameter. It is pellucid, and not much less bright than the purest crystal, and its planes are all tolerably smooth, though when nicely viewed, they are found to be waved with crooked lines made by the edges of imperfect plates. It is very soft, and easily scratched with the point of a pin; it will not give fire on being struck against steel, and ferments and is perfectly dissolved in aquafortis. It is found in Iceland, from whence it has its name; and in France, Germany, and many other places.

ISNARDIA, a genus of the monogynia order, in the tetrandia class of plants; and in the natural method ranking under the 17th order, calycanthemæ. There is one species, an aquatic and annual.

ISOCELES *triangle*, in geometry, one that has two equal sides.

ISOCHRONAL, *isochrone*, or ISOCHRONUS, is applied to such vibrations of a pendulum, as are performed in the same space of time.

ISOCHRONAL *line*, that in which a heavy body is supposed to descend without any acceleration.

ISOPERIMETRICAL *figures*, in geometry, are such as have equal perimeters, or circumferences.

1. Of isoperimetrical figures, that is the greatest which contains the greatest number of sides, or the most angles, and consequently a circle is the greatest of all figures that have the same ambit as it has.

2. Of two isoperimetrical triangles, having the same base, whereof two sides of one are equal, and of the other unequal, that is the greater of which two sides are equal.

3. Of isoperimetrical figures, whose sides are equal in number, that is the greatest which is equilateral and equiangular.

ISOCELES, *triangle*, in geometry, one that has two equal sides. See GEOMETRY.

ISSUE, in law, is sometimes used for the children begotten between a man and his wife: sometimes for profit growing from amercements or fines; and sometimes for profits of lands or tenements; sometimes for that point of matter depending in a suit, when, in the course of pleading, the parties in the case affirm a thing on one side, and deny it on the other, they are then said to be at issue.

ISSUES, in surgery, are little ulcers made designedly by the surgeon in various parts of the body, and kept open by the patient for the preservation or recovery of his health.

ITCH, a cutaneous disease, supposed to be caused by an insect, a species of the genus Acarus, viz. A. scabiei, which, when viewed by a good microscope, is white with reddish legs; the four hind ones having a long bristle. It is found in the small pellucid vesicles with which the hands and joints of persons infected with the itch are covered. It appears to be not only the cause of the disorder, but the reason why it is so highly infectious.

ITCHING, an uneasy sensation, which occasions a desire of scratching the place affected. It is frequently a troublesome sensation, but more nearly allied to pleasure than pain. As pain is supposed to proceed from too great an irritation, so does itching proceed from a slight one.

JUBILEE. This term, as at present used, signifies a grand solemnity celebrated at Rome, on which occasion the Pope grants a plenary indulgence to all descriptions of sinners; at least to as many as visit the churches of St. Peter and St. Paul at Rome. This ceremony, which is a gross perversion of the Jewish Jubilee mentioned in Scripture, was first instituted by Boniface VII. in 1300, and was only to be observed every hundred years; but as it has been found to bring in such stores of wealth to Rome, the Pope grants a jubilee as often as he and the church have occasion for it. The jubilee lasts a whole year; and was well named by the Germans the *golden year*. This year, 1825, happens to afford one of these profitable mock solemnities.

JUDGE. The judges are the chief magistrates in the law, to try civil and criminal causes. Of these there are twelve in England, viz. the Lords Chief Justices of the Courts of King's Bench and Common Pleas; the Lord Chief Baron of the Exchequer; the three puisne or inferior judges of the two former courts, and the three puisne barons of the latter. The judges are to continue in their offices during their good behaviour, notwithstanding any demise of the crown, and their full salaries are absolutely secured to them during the continuance of their commissions, by which means the judges are rendered completely independent of the king, his ministers, or his successors. A judge at his creation takes an oath that he will serve the king, and indifferently administer justice to all men, without respect of persons, take no bribe, give no counsel where he is a party, nor deny right to any, though the king or any other, by letters, or by expressed words, command the contrary, &c. and in default of duty, to be answerable to the king in body, land, and goods.

Where a judge has an interest, neither he nor his deputy can determine a cause, or sit in court, and if he do, a prohibition lies. Judges are punishable for wilful offences against the duty of their situations; instances of which happily live only in remembrance. A judge is not answerable to the king, or the party, for mistakes or errors in his judgment, in a matter of which he has jurisdiction.

JUDGMENT, among logicians, a faculty or rather act of the human soul, whereby it compares its ideas, and perceives their agreement or disagreement.

JUDGMENT. The opinion of the judges is so called, and is the very voice and final doom of the law, and therefore is always taken for unquestionable truth.

JUDGMENTS are of four sorts, viz. 1. Where the facts are confessed by the parties, and the law determined by the court, which is termed judgment by demurrer.

2. Where the law is admitted by the parties, and the facts only are disputed, as in judgment upon a demurrer.

3. Where both the fact and the law arising thereon are admitted by the defendant, as in case of judgment by confession or default.

4. Where the plaintiff is convinced that fact or law, or both, are insufficient to support his action, and therefore abandons or withdraws his prosecution, as in case of judgment upon a nonsuit or retraxit. Judgments are either interlocutory or final.

Interlocutory judgments are such as are given in the middle of a cause, upon some plea, proceeding, or default, which is only intermediate, and does not finally determine or complete the suit; as upon dilatory pleas, when the judgment in many cases is, that the defendant shall answer over; that is, put in a more substantial plea.

Final judgments, are such as at once put an end to the action by declaring that the plaintiff has either entitled himself, or has not, to recover the remedy for which he sues.

JUGLANS, the *walnut*, a genus of the monœcia class, and polyandria order of plants; and in the natural method ranking under the 50th order, amentaceæ. The male calyx is monophyllous, and squamiform; the corolla divided into six parts; there are 18 filaments; the female calyx is quadrifid superior; the corolla quadripartite; there are two styles, and the fruit is a plum with a furrowed kernel. There are eight species, the most remarkable of which is the regia or common walnut. Other two species, called the nigra and alba, or black and white Virginian walnut are also cultivated in this country, though they are less proper for fruit, having very small kernels.

The wood of the walnut tree is much used by cabinet-makers, coach-makers, and gun-smiths; is susceptible of a very fine polish, and exhibits a beautiful grain.

JUGULAR. See ANATOMY.

JUGULARES, in the Linnæan system, is the name of an order or division of fish, the general character of which is that they have ventral fins.

JULIAN *period*, in chronology, a system or period of 7980 years, found by multiplying the three cycles of the sun, moon, and indiction into one another. See CHRONOLOGY. This period was called the Julian, not because invented by Julius Cæsar; since the Julian epocha was not received till the year 4669, but because the system consists of Julian years.

JUNCUS, the rush, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 5th order, tripetaloideæ. The calyx is hexaphyllous; there is no corolla; the capsule is unilocular. There are 29 species universally known, being very troublesome weeds, and difficult to be eradicated. The pith of two kinds, called the conglomeratus and effusus, or round-headed and soft rushes, is used for wicks to lamps and rushlights. The conglomeratus, and aculus or marine rush, are planted with great care on the banks of the sea in Holland, in order to prevent the water from washing away the earth; which would otherwise be removed every tide, were it not for the roots of those rushes, which fasten very deep in the ground, and mat themselves near the surface in such a manner as to hold the earth closely together.

JUNGERMANNIA, a genus of the natural order of algæ, in the cryptogamia class of plants. There are 48 species, all natives of Britain, growing in woods, shady places, by the sides of ditches, &c. Many of them are beautiful objects for the microscope.

JUNIPERUS, the juniper tree; a genus of the monadelphia order, in the monœcia class of plants; and in the natural method ranking under the 51st order, coniferæ. The male amentum is a calyx of scales; there is no corolla; three stamina; the female calyx tripartite; there are three petals, and as many stiles; the berry is trispermous, and equal, by means of three tubercles of the indurated calyx adhering to it. There are 12 species; the most remarkable are, 1. The communis, or common juniper, grows naturally in many parts of Britain upon dry barren commons, where it seldom rises above the height of a low shrub, which grows naturally only in dry, chalky, or sandy land. Juniper-berries have a strong, not disagreeable smell; and a warm, pungent, sweet taste, which, if they are long chewed, or previously well bruised, is followed by a bitterish one. The pungency seems to reside in the bark; the sweet in the juice; the aromatic flavour in oily vesicles spread through the substance of the pulp, and distinguishable even by the eye; and the bitter in the seeds.

JUPITER, ♃, in astronomy, one of the superior planets, remarkable for its great brightness. See ASTRONOMY.

JURY. This strong tower of defence of the British Constitution, which is one of the leading features of the Magna Charta, is composed of a certain number of persons sworn to enquire of, and try some fact, and declare the truth upon the evidence brought before them.

Juries are divided into two kinds, viz. common and special. A common jury is such as is returned by the sheriff, according to the directions of the statute 3 Geo. II. cap. 25, which appoints that the sheriff's officer shall not return a separate pannel for every separate cause, but one and the same pannel for every cause to be tried at the same assizes, containing not less than forty-eight, nor more than seventy-two jurors; and their names being written on tickets

shall be put into a box or glass, and when each cause is called, twelve of those persons whose names shall be first drawn out of the box shall be sworn upon a jury, unless absent, challenged, or excused. When a sufficient number of persons are impanelled, they are then separately sworn, well and truly to try the issue between the parties, and a true verdict give according to the evidence.

Special juries were originally introduced in trials at bar, when the causes were of too great nicety for the discussion of ordinary freeholders. To obtain a special jury, a motion is made in court, and a rule is granted thereupon, for the sheriff to attend the master, prothonotary, or other proper officer, with his freeholder's book, and the officer is to take indifferently forty-eight of the principal freeholders, in the presence of the attornies on both sides, who are each of them to strike off twelve, and the remaining twenty-four are returned upon the panel. Jurors are punishable for sending for, or receiving, instructions from either of the parties concerning the matter in question. In causes of nisi prius, every person whose name shall be drawn, and who shall not appear after being openly called upon three times, shall, on oath made of his having been lawfully summoned, forfeit a sum not exceeding 5*l.*, nor less than 40*s.*, unless some reasonable cause of absence be proved, by oath or affidavit, to the satisfaction of the judge. If any juror shall take of either party to give his verdict, he shall, on conviction, by bill or plaint, before the court where the verdict shall pass, forfeit ten times as much as he has taken; half to the king, and half to him who shall sue. A man who shall assault or threaten a juror for giving a verdict against him, is highly punishable by fine and imprisonment; and if he strike him in the court, in the presence of the judge of assize, he shall lose his hand and his goods, and the profits of his lands during life, and suffer perpetual imprisonment.

IVORY. The tusk, or tooth of defence of the male elephant. It is an intermediate substance between bone and horn, not capable of being softened by fire, not altogether so hard and brittle as bone. Sometimes it grows to an enormous size, so as to weigh near two hundred pounds. The entire tooth is of a yellowish, brownish, and sometimes a dark brown colour on the outside, internally white, hollow towards the root, and so far as was inserted into the jaw, of a blackish-brown colour. The finest, whitest, smoothest, and most compact ivory comes from the island of Ceylon. The grand consumption of this commodity is for making ornamental utensils, mathematical instruments, cases, boxes, balls, combs, dice, and an infinity of toys. The workmen have methods also of tinging it to a variety of colours.

The coal of ivory is used in the arts under the denomination of ivory black. Particular vessels are used in the manufacture of this pigment, for the purpose of rendering it perfectly black. Some travellers speak of the tooth of the sea-horse as an excellent ivory; but it is too hard to be sawed or wrought like ivory. It is used for making artificial teeth

JURY-*mast*, whatever is set up in room of a mast that has been lost in a storm or in an engagement, and to which a lesser yard, ropes, and sails are fixed.

JUSSIÆA, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 17th order, calycanthemæ. There are 11 species, mostly herbaceous plants of the West Indies.

JUSTICE, in a legal sense, a person deputed by the king to administer justice to his subjects, whose authority arises from his deputation, and not by right of magistracy. In the courts of king's bench and common pleas there are two judges styled chief justices, each of whom retains the title of lord during the time of his continuing in office. The first of these, who is styled lord chief justice of England, has a very extensive power and jurisdiction in pleas of the crown. He hears all pleas in civil causes brought before him in the court of king's bench, and also the pleas of the crown; while, on the other hand, the lord chief justice of the common pleas has the hearing of all civil causes between common persons. Besides the lords chief justices, there are in each of the above courts three puisne justices; there are also several other justices appointed by the king for the execution of the laws; such as the lords justices in eyre of the forests, who are two justices appointed to determine all offences committed in the king's forests; justices of assize, of oyer and terminer, of gaol delivery, &c. They are also called justices of nisi prius, and so denominated from the words used in a common form of adjournment of a cause in the court of common pleas.

Justices *of the Peace*. See Peace.

JUSTICIARY, or court of Justiciary, in Scotland, a court of supreme jurisdiction in all criminal cases.

This court came in place of the justice-eyre or justice-general, which last was taken away by parliament in 1672, and was erected into a justice or criminal court, consisting of a justice-general alterable at the monarch's pleasure, justice-clerk, and five other judges, who are lords of session.

JUSTICIES, a writ directed to a sheriff, by virtue of which he is empowered to hold a plea of debt in his county-court for a sum above 40*s.* though by his ordinary power he has only cognizance of sums under 40*s.*

JUSTIFICATION, in law, is an affirming or shewing good reason in court, why one does such a thing as he is called to answer; as to justify in a cause of a replevin.

IVY. See Hedera.

IXIA, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the sixth order, ensatæ. The corolla is hexapetalous, patent, and equal; there are three stigmata, a little upright and petalous. There are fifty-four species, consisting of herbaceous, tuberous, and bulbous-rooted flowery perennials, from one to two feet high, terminated by hexapetalous flowers of different colours

K.

K, or k, the tenth letter of the English alphabet; it is derived from the Greek K or κ and seems to have been unknown to the Romans, though we sometimes meet with kalendar for calendar. As a numeral. K denotes 250; and with a line over it, K 250,000.

KÆMPFERIA, *zedoary*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. The corolla is sexpartite, with three of the segments larger than the rest, patulous; and one only bipartite. The species are, 1. The [illegible] galanga, common galangal, or long zedoary. 2. The rotunda, or round zedoary. Both are perennial in root; but the leaves rise annually in spring, and decay in winter.

KALEIDOSCOPE. This term has been applied to designate a new optical instrument, invented by Dr. Brewster, of Edinburgh, for the purpose of creating and exhibiting an endless variety of beautiful and perfectly symmetrical figures. The word is of Greek derivation, and is compounded of καλος, *beautiful*, ειδος, *a form*, and σκοπεω, *to see*.

The kaleidoscope is an instrument so well known, that a particular description of it would be superfluous. It may, therefore, suffice simply to state the principles of its construction. When the instrument was brought by the inventor to something like a state of perfection, Dr. Brewster, at the solicitation of his friends, took out a patent for it, as a "new optical instrument for creating and exhibiting beautiful forms." In the specification of his patent, he describes the kaleidoscope in two different forms. The first consists of two reflecting planes, placed in a tube with an eye-hole in the particular position, which gives symmetry and a maximum uniformity of light, and with objects, such as coloured glass, *placed in the position of symmetry, and put in motion, either by a rotary movement, or by their own gravity, or by both combined.*

The second form of the instrument, described in the specification, is, when the tube containing the reflectors is placed in a second tube, at the end of which is a convex lens, which introduces into the picture objects of all magnitudes, and at every distance.

The kaleidoscope has been fitted up in a very elegant and scientific manner by the opticians of London; its utility has been experienced chiefly by calico-printers, potters, and carpet manufacturers: as a source of amusement it is endless, as the changes effected by its motion are ever varying. No instrument ever produced such an effect on the public feeling; but it must be owned that it lost much which it might otherwise have gained in the public estimation, by the thousands of unscientific imitations of it, which were sold in every part of the country, when the invention became known.

KALI, a genus of marine plants, which are burnt to procure mineral alkali.

KALMIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 18th order bicornes. Of this genus there are four species. Those chiefly in cultivation with us are,

1. The latifolia, a most beautiful shrub, which rises usually to the height of five or six feet, and sometimes twice that height in its native places. This plant is a native of Carolina, Virginia, and other parts of America, yet it is not common; it grows on rocks hanging over rivulets, and on the sides of barren hills.

2. The angustifolia, rises to the height of about 16 feet, with evergreen leaves. flowers grow in clusters, and when blown, appear white; but on a near view, are of a faint bluish colour, which, as the flower decays, grows paler.

KAMSIN, a hot southerly wind, common in Egypt. It prevails more or less for fifty days. The sky becomes dark and heavy, the sun loses its splendour, and appears of a violet colour; the air is not cloudy, but grey and thick, and is filled with a dust so subtile, that it penetrates every where. This wind, always light and rapid, is not at first remarkably hot, but it increases in heat in proportion as it continues. The lungs, which a too rarefied air no longer expands, are contracted and become painful. Respiration is short and difficult, the skin parched and dry, and the body consumed by an internal heat. It usually lasts three days, but if it exceeds that time, it becomes insupportable. The danger is most imminent when it blows in squalls; for then the rapidity of the wind increases the heat to such a degree as to cause sudden death. This death is a real suffocation. The best mode of preventing the effects of it is to stop the nose and mouth with handkerchiefs. The camels, on this occasion, bury their noses in the sand, and keep them there till the squall is over. Another quality of this wind is its extreme aridity; which is such, that water sprinkled on the floor evaporates in a few minutes.

KAOLIN, the name of an earth which is used as one of the two ingredients in oriental porcelain.

KEDDING, in the sea-language, is when a ship is brought up or down a river by means of the tide, the wind being contrary.

KEEL, the lowest piece of timber in a ship, running her whole length from the lower part of her stem to the lower part of her stern-post. Into it are all the lower futtocks fastened; and under part of it, a false keel is often used.

Keel-*hauling*, a punishment inflicted for various offences in the Dutch navy. It is performed by suspending the culprit by a rope from one yard-arm, with a weight of lead or iron upon his legs, and having another rope fastened to him, leading under the ship's bottom, and through a block at its opposite yard-arm; he is then repeatedly and suddenly let fall from the one yard-arm into the sea, where passing under the ship's bottom, he is hoisted upon the opposite side of the vessel to the other.

KEELERS, among seamen, are small tubs, which hold stuff for the caulking of ships.

KEELSON, a principal timber in a ship, fayed within-side cross all the floor-timbers; and being adjusted to the keel with suitable scarfs, it serves to strengthen the bottom of the ship.

KEEP, in ancient military history, a kind of strong tower, which was built in the centre of a castle or fort, to which the besieged retreated, and made their last efforts of defence. Of this description is the keep of Windsor Castle.

KEEPER *of the great seal*, is a lord by virtue of his office, and styled the lord keeper of the great seal of England. He is one of the king's privy council, through whose hands pass all charters, commissions, and grants of the king under the great seal; without which, all such instruments by law are of no force,

Keeper *of the privy seal*, is a lord by virtue of his office, through whose hands pass all charters signed by the king before they come to the great seal. He is of the king's privy council.

KEEPING, in painting, signifies the representation of objects in the same manner that they appear to the eye at different distances from it, which is only to be done with accuracy by attending to the rules of perspective.

KELP, an impure alkali, obtained in the north of Scotland, from different kinds of fuci, or sea weed. The weeds being dried, are burned in pits dug in the sand, or on the surface, surrounded with loose stone, fresh quantities being added, and the whole being frequently stirred until it becomes semi-fluid, which, when cold, forms hard masses. About twenty-four tons of the weed are requisite to produce one ton of kelp. Kelp is usually employed in making soap; for this purpose saturated solution is obtained by hot water; the refuse, after this operation, is used in the manufacture of bottle glass.

KERMES. See Coccus.

Kermes *Mineral.* Sulphuretted hydrogen forms, with the deutoxide of antimony, a compound which possessed at one time great celebrity in medicine, and of which a modification has lately been introduced into the art of calico printing. By dropping hydrosulphuret of potash, or of ammonia, into the cream tartrate, or into mild muriate of antimony, the hydrosulphuret of the metallic oxide, precipitates of a beautiful deep orange colour. This is *kermes mineral.* Cluzel's process for obtaining a fine

subcarbonate of soda, and 200 parts of water, are to be boiled together in an iron pot. Filter the hot liquor into warm earthen pans, and allow them to cool very slowly. At the end of 24 hours the kermes is deposited. Throw it on a filter, wash it with water which had been boiled and then cooled out of contact with air. Dry the kermes at a temperature of 85°, and preserve it in corked phials.

KETCH, a vessel equipped with two masts, viz. the main-mast and the mizen-mast, and usually from 100 to 250 tons burthen. Ketches are principally used as yachts for conveying princes of the blood, ambassadors, or other great personages, from one place to another. Ketches are likewise used as bomb-vessels.

Ketches, *bomb*, are built remarkably strong as being fitted with a greater number of riders than any other vessel of war.

KEY, a well known instrument for opening and shutting the locks of doors, chests, &c. See Lock.

Key, or *key note*, in music a certain fundamental note or tone, to which the whole of a movement has a certain relation or bearing, to which all its modulations are referred and accommodated, and in which it both begins and ends. There are but two species of keys: one of the major, and one of the minor mode: all the keys in which we employ sharps or flats being deduced from the natural keys of C major and A minor; of which they are mere transpositions.

KIDNAPPING, is the forcible taking and carrying away a man, woman, or child, from their own country, and sending them to another, This is an offence at common law, and punishable by fine, imprisonment, and pillory.

By stat. 11 and 12 W. III. c. 7, if any captain of a merchant vessel shall, during his being abroad, force any person on shore, and wilfully leave them behind, or refuse to bring home all such men as he carried out, if able and desirous to return, he shall suffer three months' imprisonment. Exclusive of the above punishment for this as a criminal offence, the party may recover upon an action for compensation in damages for the civil injury.

KIDNEYS. See Anatomy.

KIFFEKIL. See Meerschaum.

KIGGELARIA, a genus of the decandria order, in the diœcia class of plants, and in the natural method ranking under the 37th order, columniferæ. There is but one species, viz. the Africana.

KILDERKIN, a liquid measure containing two firkins, or 18 gallons.

KING, signifies him who has the highest power and absolute rule over the whole land; and therefore the king is, in intendment of law cleared of those defects which common persons are subject to; for he is always supposed to be of full age, though ever so young. The law ascribes to his majesty, in his political capacity, an absolute immortality. The king never dies; for immediately on the decease of the reigning prince in his natural capacity, his imperial dignity, by act of law, without any interregnum or interval, is vested at once in his heir, who is eo instanti king to all intents and purposes And so tender is the law of supposing even a possibility of his death, that his natural dissolution is generally called his demise, an expres-

sons marrying papists, are for ever excluded from the imperial crown of Great Britain; and in such case, the crown shall descend to such person being a protestant, as should have inherited the same, in case such papist, or person marrying a papist, was naturally dead.

King's-bench. The king's-bench is the supreme court of common law in the kingdom, and is so called, because the king used to sit there in person; it consists of a chief justice, and three puisne justices, who are by their office the sovereign conservators of the peace, and supreme coroners of the land. This court has a peculiar jurisdiction, not only over all capital offences, but also over all other misdemeanors of a public nature, tending either to a breach of the peace, or to oppression or faction, or any manner of misgovernment. It has a discretionary power of inflicting exemplary punishment on offenders, either

by fine, imprisonment, or other infamous punishment, as the nature of the crime, considered in all its circumstances, shall require. The jurisdiction of this court is so transcendant, that it keeps all inferior jurisdictions within the bounds of their authority, and it may either remove their proceedings to be determined here, or prohibit their progress below: it superintends all civil corporations in the kingdom; commands magistrates and others to do what their duty requires, in every case where there is no specific remedy; protects the liberty of the subject, by speedy and summary interposition; takes cognizance both of criminal and civil causes; the former in what is called the crown side, or crown office; the latter in the plea side of the court. This court has cognizance on the plea side of all actions of trespass, or other injury alleged to be committed *vi et armis*, of actions for forgery of deeds, maintenance, conspiracy, deceit, and actions on the case which allege any falsity or fraud. In proceedings in this court, the defendant is arrested for a supposed trespass, which in reality he has never committed; and being thus in the custody of the marshal of this court, the plaintiff is at liberty to proceed against him for any other personal injury, which surmise of being in the custody of the marshal, the defendant is not at liberty to dispute. This court is likewise a court of appeal, into which may be removed, by writ of error, all determinations of the court of common pleas, and of all inferior courts of record in England.

KNAPSACK, a rough leather or canvas bag, which is strapped to an infantry soldier's back when he marches, and which contains his necessaries. Square knapsacks are supposed to be most convenient. They should be made with a division to hold the shoes, blacking-balls, and brushes, separate from the linen.

KNAUTIA, a genus of the mongynia order, in the tetrandria class of plants, and in the natural method ranking under the 48th order, aggregate. There are four species, chiefly annuals of the Levant.

KNEE. See ANATOMY

KNEE, in a ship, a crooked piece of timber, bent like a knee, used to bind the beams and futtocks together, by being bolted fast into them both.

KNIGHT, properly signifies a person, who for his virtue and martial prowess, is by the king raised above the rank of a gentleman, into a higher class of dignity and honour. The ceremonies at the creation of knights have been various; the principal was a box on the ear, and a stroke with a sword on the shoulder; they put on him a shoulder belt, and a gilt sword, spurs, and other military accoutrements; after which, being armed as a knight, he was led to the church in great pomp. Camden describes the manner of making a knight-bachelor among us, which is the lowest, though the most ancient order of knighthood, to be thus: the person kneeling was gently struck on the shoulder by the prince, and accosted in these words, "rise," or "be a knight in the name of God."

KNIGHTS *of the shire*, or KNIGHTS *of parliament*, in the British polity, are two knights or gentlemen of estate, who are elected on the king's writ, by the freeholders of every county, to represent them in parliament. The qualification of a knight of the shire is to be possessed of £600 per ann. in a freehold estate.

KNOT, means the division of the log-line used at sea. These are usually seven fathoms or forty-two feet; they ought to be fifty feet, and then as many knots as the log-line runs out in half a minute, so many miles does the ship sail in an hour, supposing her to keep going at an equal rate.

KNOTS *of a rope*, among seamen, are distinguished into three kinds, viz. whole-knot, that made so with the lays of a rope that it cannot slip, serving for sheets, tacks, and stoppers: bow-link-knot, that so firmly made and fastened to the cringles of the sails, that they must break or the sail split before it slips; and sheep-shank-knot, that made by shortening a rope without cutting it.

KNOWLEDGE, is defined by Mr. Locke, to be the perception of the connection and agreement, or disagreement and repugnancy of our ideas.

KNOXIA, a genus of the class and order tetrandria monogynia. The corolla is one petalled, funnel-form; seeds two grooved. There is one species, an herb of Ceylon.

KORAN, or ALCORAN, the scripture or bible of the Mahometans; containing the revelations and doctrines of their pretended prophet.

That Mahomet was the author of the Koran is allowed both by Christians and the Mahometans themselves; only the latter are fully persuaded that it was revealed to him by the ministry of the angel Gabriel; whereas the former with more reason, think it all his own invention, assisted by one Sergius, a Christian monk.

The Koran is divided into 114 larger portions of very unequal length, which we call chapters, but the Arabians *sowar*, in the singular *sura;* a word rarely used on any other occasion, and properly signifying a row, or a regular series. These chapters are not, in the manuscript copies, distinguished by their numerical order, but by particular titles, which are sometimes taken from a particular subject treated of, or persons mentioned in them, usually from the first word of note. But the Koran is more usually divided into thirty sections only, each of twice the length of the former, and in like manner subdivided into four parts. These divisions are for the use of the readers of the Koran in the royal temples, or in the adjoining chapels, where the emperors and great men are interred.

After the title at the head of each chapter, except the ninth, is prefixed the formula, "In the name of the most merciful God," called by the Mahometans Bismallah, wherewith they constantly begin all their books and writings as the distinguishing mark of their religion.

The Koran is universally allowed to be written with the utmost elegance and purity of language, in the dialect of the tribe of Koreish the most noble and polite of all the Arabians, but with some mixture, though very rarely, of other dialects: and it is confessedly the standard of the Arabic tongue.

The general aim of the Koran was, to unite the professors of the three different religions then followed in Arabia, Idolaters, Jews, and

Christians, in the knowledge and worship of one God, under the sanction of certain laws, and the outward signs of ceremonies, partly of ancient and partly of novel institution, enforced by the consideration of rewards and punishments, both temporal and eternal, and to bring all to the obedience of Mahomet, as the prophet and ambassador of God, who was to establish the true religion on earth, and be acknowledged chief pontiff in spiritual matters. The chief point, therefore, inculcated in the Koran, is the unity of God, to restore which, the prophet confessed was the chief end of his mission. The rest is taken up in prescribing necessary laws and directions, frequent admonitions to moral and divine virtues, the worship and reverence of the Supreme Being, and resignation to his will.

So numerous are the commentaries on the Koran, that a catalogue of their bare titles would make a volume: we have a very elegant translation of it into English by Mr. Sale; who has added a preliminary discourse, with other occasional notes, which the curious may consult on this head.

KOUMISS. A vinous liquid, which the Tartars make by fermenting mare's milk. Something similar is prepared in Orkney and Shetland.

KUPFERNICKEL, is a sulphuret of nickel, and is generally compounded of nickel, arsenic, and sulphuret of iron.

KURTUS, in natural history, a genus of fishes of the order jugulares. Generic character; body carinated above and below and broad; back highly elevated, gill membrane, with two rays. It inhabits the seas of India. Its length is about ten inches, and its breadth four. Its colour, on the whole body, is that of silver foil, and its back is tinged with gold, and marked on its ridge with several black spots.

KYANITE. See Cyanite.

KYLLINGIA, in botany, a genus of the triandria monogynia class and order. Natural order of gramina. Cyperoideæ, Jussieu. Essential character, ament ovate or oblong, imbricate; flowers with a bivalve calyx and corolla. There are seven species, natives of the East and West Indies.

L.

L, or *l*, the eleventh letter of the English alphabet, denotes as a numeral, 50; and with a dash over it thus $\bar{L}$, 50,000.

LA, in music, the syllable by which Guido denoted the last sound of each hexachord: if it begins in C, it answers to our A; if in G to E; and if in F to D.

LABARUM, in Roman antiquity, the standard borne before the Roman emperors; being a rich purple streamer, supported by a spear.

LABDANUM, or Ladanum. A resin of a species of cistus in Candia, of a blackish colour. The country people collect it by means of a staff, at the end of which are fastened many leather thongs, which they gently strike on the trees. They form it into cylindrical pieces; which are called *labdanum in tortis*. It is greatly adulterated by the addition of black sand. It has been used in cephalic and stomachic plasters and perfumes.

LABORATORY, signifies a place properly fitted up for the performance of chemical operations. Having referred the reader in several instances to this article for an account of different articles of chemical apparatus, which could not be so well described apart from each other, we shall here give the subject its full proportion of attention.

To attempt to offer the plan of a laboratory, which would be suitable to every person, and to all situations, would be highly preposterous; we shall therefore content ourselves with noticing a few leading particulars, at the same time remarking, that the experimentalist will soon discover that by a judicious combination of the following apparatus, a very extensive series of operations may be carried on.

It may be proper to notice here, for the sake of those who, in fitting up a laboratory, have it in their power to choose the situation of it, that a ground floor ought never to be chosen, unless it can be effectually secured from the effects of damp, which have always a most pernicious influence on many of the substances constantly in use in a chemical laboratory.

A laboratory, therefore, is more advantageously placed above than below the ground, that it may be as dry as possible. The air must have free access to it; and it must even be so constructed, that by means of two or more opposite openings, a current of air may be admitted, to carry off any noxious vapours or dust.

In the laboratory a chimney ought to be constructed, so high that a person may easily stand under it, and as extensive as is possible; that is, from one wall to another. The funnel of this chimney ought to be high, and sufficiently contracted to make a good draught. As charcoal only is burnt under this chimney, no soot is collected in it; and therefore it need not be so wide as to allow a chimney-sweeper to pass up into it.

Under this chimney may be constructed some brick furnaces, particularly a melting furnace, a furnace for distilling with an alembic, and one or two ovens like those in kitchens. The rest of the space ought to be filled up with stands of different heights, from a foot to a foot and a half, on which portable furnaces of all kinds are to be placed. These furnaces are the most convenient, from the facility of disposing them at pleasure; and they are the only furnaces which are necessary in a small laboratory. A double pair of bellows of a moderate size must also be placed as commodiously under the chimney, or as near as the place will allow. These bellows are sometimes mounted in a portable frame; which is sufficiently convenient when the bellows are not more than eighteen or twenty inches long. These bellows ought to have a pipe directed toward the hearth where the forge is to be placed.

The necessary furnaces are, the simple furnace, for distilling with a copper alembic; a

lamp furnace; two reverberatory furnaces of different sizes, for distilling with retorts; an air or melting furnace, an assay furnace, and a forge furnace.

Under the chimney, at a convenient height, must be a row of hooks driven into the back and side walls; upon which are to be hung small articles, as iron pans, tongs, straight, crooked, and circular pincers, pokers, &c. To the walls of the laboratory ought to be fastened shelves of different breadths and heights; or these shelves may be suspended by hooks. The shelves are to contain glass vessels, and the products of operations, and ought to be in as great a number as is possible. In a laboratory where many experiments are made, there cannot be too many shelves. The most convenient place for a stone or leaden cistern, to contain water, is a corner of the laboratory, and under it a sink ought to be placed with a pipe, by which the water poured into it may discharge itself. As the vessels are always cleaned under this cistern, cloths and bottle brushes ought to be hung upon hooks fastened in the walls near it.

In the middle of the laboratory a large table is to be placed, on which mixtures are to be made, preparations for operations, solutions, precipitations, small filtrations; in a word, whatever does not require fire, excepting that of a lamp.

In convenient parts of the laboratory are to be placed blocks of wood upon mats; one of which is to support a middle-sized iron mortar, another to support a middle sized marble, or rather hard stone mortar; a third to support an anvil. Near the mortars are to be hung searces of different sizes and fineness; and near the anvil a hammer, files, rasps, small pincers, scissars, sheers, and other small utensils, necessary to give metals a proper form for the several operations.

Two moveable trestles ought to be in a laboratory, which may serve to support a large filter mounted upon a frame, when it is required. This apparatus is removed occasionally to the most convenient place.

Charcoal is an important article in a laboratory, and it therefore must be placed within reach; but as the black dust which flies about it whenever it is stirred, is apt to soil every thing in the laboratory, it had better be in some place near the laboratory, together with some furze, which is very convenient for kindling fires quickly. This place serves, at the same time, for containing bulky things which are not often wanted: such as furnaces, bricks, tiles, clay, fire-clay, quicklime, sand, and many other things necessary for chemical operations.

Lastly, a middle-sized table, with solid feet, ought to be enumerated among the large moveables of a laboratory, the use of which is to support a porphyry, or levigating stone, or rather a very hard and dense gritstone, together with a muller made of the same kind of stone.

The other small moveables or utensils of a laboratory are, small hand mortars of iron, glass, agate, and Wedgewood's ware, and their pestles; earthern, stone, metal, and glass vessels, of different kinds, funnels, and measures. Some white writing paper, and some unsized paper for filters; a large number of clean straws, eight or ten inches long, for stirring mixtures in glasses, and for supporting paper filters placed in glass funnels. Glass tubes for stirring and mixing corrosive liquors; spatulas of wood, ivory, metal, and glass.

Thin pasteboards and horns, very convenient for collecting matters bruised with water upon the levigating stone, or in mortars; corks of all sizes; bladders and linen strips for luting vessels.

A good portable pair of bellows; a good steel for striking fire; a glue-pot, with its little brush; lastly, a great many boxes, of various sizes, for containing most of the above-mentioned things, and which are to be placed upon the shelves.

Besides the above, there are many substances which the operator must be possessed of, and which, indeed, may be considered as part of his instruments; these substances are called reagents. The plate annexed, with the following explanation of the different articles there delineated, will give the student an idea of the most useful parts of modern chemical apparatus.

Figures, 1, 2, 3, plate XXV. are crucibles or pots, made either of fire-clay, black lead, forged iron, or platina. They are used for roasting, calcination, and fusion

Figs. 4, 5, 6, are cucurbits, matrasses, or bodies, which are glass, earthenware, or metallic vessels, usually shaped like an egg, and open at top. They serve the purposes of digestion, evaporation, &c.

Retorts are globular vessels of earthern ware, glass, or metal, with a neck bended on one side. Some retorts have another neck or opening at their upper part, through which they may be charged, and the opening may be afterwards closed with a stopple. These are called tubulated retorts. A Welter's tube of safety may be inserted in this opening, instead of a stopple. See fig. 7, 8, *b*, *c*.

Receivers are vessels, usually of glass, of a spherical form, with a straight neck, into which the neck of the retort is usually inserted. When any proper substance is put into a retort, and heated, its volatile parts pass over into the receiver, where they are condensed. See fig. 9.

Fig. 10. The alembic is used for distillation, when the products are too volatile to admit of the use of the last mentioned apparatus. The alembic consists of a body *a*, to which is adapted a head *b*. The head is of a conical figure, and has its external circumference or base depressed lower than its neck, so that the vapours which rise, and are condensed against its sides, run down into the circular channel formed by its depressed part, from whence they are conveyed by the nose or beak *c*, into the receiver *d*.

Frequently, however, the flame of an Argand lamp may be employed very conveniently for chemical purposes. Fig. 11, is a representation of a lamp furnace, as it is perhaps not very properly called, as improved by Mr. Accum. It consists of a brass rod screwed to a foot of the same metal, loaded with lead. On this rod, which may be unscrewed in the middle for rendering it more portable, slide three brass sockets with straight arms, terminating in brass rings of different diameters. These rings serve for supporting glass alembics, retorts, Florence flasks, evaporating basins, gas bottles, &c.; for performing distillations, digestions solutions evaporations, saline fusions, concentrations,

analyses with the pneumatic apparatus, &c. If the vessels require not to be exposed to the naked fire, a copper sand bath may be interposed, which is to be previously placed in the ring. By means of a thumb-screw acting on the rod of the lamp, each of the brass rings may be set at different heights, or turned aside, according to the pleasure of the operator. Below these rings is a fountain lamp on Argand's plan, having a metallic valve within, to prevent the oil from running out while the reservoir is put into its place. This lamp also slides on the main brass rod by means of a socket and thumb-screw.

For experiments on gases, the following apparatus called the pneumatic trough, will be found exceedingly useful. It may be made of wood, or japanned iron, or of copper, and of any form that suits the conveniency of the chemist.

Fig. 12, *a* represents a wooden vessel or tub; *k k k*, is a shelf fixed in the tub. When this apparatus is used, the tub is to be filled with water to such a height, as to rise about one inch above the upper surface of the shelf. *b, g, f*, are glass jars inverted with their mouths downward, which rest upon the shelf. If these, or any other vessels open only at one end, be plunged under the water, and inverted after they are filled, they will remain full, notwithstanding their being raised out of the water, provided their mouths be kept immersed; for in this case the water is sustained by the pressure of the atmosphere, in the same manner as the mercury in the barometer. It may without difficulty be imagined, that if common air, or any other fluid resembling common air in lightness and elasticity, be suffered to enter these vessels, it will rise to the upper part, and the surface of the water will subside. In this manner air may be emptied out of one vessel into another by an inverted pouring, in which the air is made to ascend from the lower vessel *i* to the upper *g*, in which the experiments are performed by the action of the weightier fluid, exactly similar to the common pouring of denser fluids detained in the bottoms of open vessels, by the simple action of gravity. When the receiving vessel has a narrow neck, the air may be poured through a glass funnel *h*. *c* is a glass body or bottle, the bottom of which is blown very thin, that it may support the heat of a candle suddenly applied, without cracking. In its neck is fitted, by grinding, a tube *d*, curved neatly in the form of the letter *s*. This kind of vessel is very useful in various chemical operations, for which it will be convenient to have them of several sizes. In the figure, the body *c* is represented as containing a fluid, in the act of combining with a substance that gives out air, which passes through the tube into the jar *b*, under the mouth of which the other extremity of the tube is placed. At *e* is a small retort of glass or earthern ware, the neck of which being plunged in the water, beneath the jar *f*, is supposed to emit the elastic fluid, extricated from the contents of the retort, which is received in the jar.

When any thing, as a gallipot, is to be supported at a considerable height within a jar, it is convenient to have such wire-stands as are represented fig. 13

In order to expel air from solid substances by means of heat, a gun-barrel, with the touch-hole screwed up and rivetted, may be used instead of an iron retort. The subject may be placed in the chamber of the barrel, and the rest of the bore may be filled with dry sand, that has been well burned, to expel whatever air it might have contained. The stem of a tobacco-pipe, or a small glass tube, being luted in the orifice of the barrel, the other extremity must be put into the fire, that the heat may expel the air from its contents. This air will of course pass through the tube, and may be received under an inverted vessel, in the usual manner.

But the most accurate method of procuring air from several substances, by means of heat, is to put them, if they will bear it, into phials full of quicksilver, with the mouths inverted in the same, and then throw the focus of a burning lens or mirror upon them.

Many kinds of air combine with water, and therefore require to be treated in an apparatus in which quicksilver is made use of. This fluid being very ponderous and of considerable price, it is an object of convenience, as well as economy, that the trough and vessels should be smaller than when water is used. See plate XXVI. Fig. 6.

It is sometimes desirable to impregnate water for medicinal purposes with some gas, as the carbonic acid, and for this the apparatus of Dr. Nooth is very effectual and convenient. It consists of three glass vessels, plate XXIV. fig. 4. The lower vessel *c* contains the effervescent materials; it has a small orifice at *d*, stopped with a ground stopper, at which an additional supply of either acid, or water, or chalk, may be occasionally introduced. The middle vessel *b* is open, both above and below. Its inferior neck is fitted, by grinding, into the neck *h* of the lower vessel. In the former is a glass valve, formed by two pieces of tube, and a plano-convex lens, which is moveable between them. This valve opens upwards, and suffers the air to pass; but the water cannot run through the tubes. The middle vessel is furnished with a cock *e*, to draw off its contents. The upper vessel *a* is fitted, by grinding, into the upper neck of the middle vessel. Its inferior part consists of a tube that passes almost as low as the centre of the middle vessel. Its upper orifice is closed by a ground stopper *f*. When this apparatus is to be used, the effervescent materials are put into the lower vessel; the middle vessel is filled with pure water, and put into its place; and the upper vessel is stopped, and likewise put in its place. The consequence is, that the carbonic acid gas, passing through the valve at *h*, ascends into the upper part of the middle vessel *b*, where, by its elasticity, it reacts on the water, and forces part up the tube into the vessel *a*; part of the common air, in this last, being compressed, and the rest escaping by the stopper, which is made of a conical figure, that it may be easily raised. As more carbonic acid is extricated, more water rises, till at length the water in the middle vessel falls below the lower orifice of the tube. The gas then passes through the tube into the upper vessel, and expels more of the common air by raising the stopper. In this situation the water in both vessels being in contact with body of carbonic acid gas, it becomes strongly impregnated with this gas, after a certain time.

Sometimes it is requisite to obtain separately the condensable fluid that comes over, and the gases that are, and are not soluble in water. For this purpose a series of receivers, more or less in number as the case may require, is generally employed, as in plate XXV. fig. 1, which represents what is called Woolfe's apparatus, though in fact its original inventor was Glauber, with some subsequent improvements. The vapour that issues from the retort being condensed in the receiver *a*, the gas passes on through a bent tube into the bottle *c*, which is half filled with water. The gas not absorbed by this water, passes through a similar bent tube to *d*, and so on to more, if it be thought necessary; while the gas that is not absorbed by water, or condensable, at its exit from the last bottle is conveyed by a recurved tube into a jar *g*, standing in a mercurial trough *f f*.

A very simple and commodious form of a Woolfe's apparatus is given by the late Dr. W. Hamilton, at the end of his translation of Berthollet on Dyeing; see pl. XXIV fig. 1: *a*. is the retort, the neck of which is ground into and passed through the thick collar *b*, represented separately at *b*: with its ground stopple *a* which may be put in when the neck of the retort is withdrawn. The collar *b* is ground into the wide neck of the receiver *c*, the narrow neck of which is ground into the wide neck of *d*. *d*, *e*, *f*, and *g*, are connected in a similar manner; and into the small necks of *d*, *e*, and *f*, are ground the tubes *i*, *k*, and *l*, so curved, that their lower extremities nearly reach the bottom of the receiver into which they open. From the last receiver proceeds the recurved tube *m*, opening under an inverted cup *n*, a hole in the bottom of which conveys the gas issuing from it into one of the bottles placed in the moveable frame *p*, which has a heavy leaden foot to keep it steady in the centre of a flat pan of water, in which the mouths of the bottles are immersed. In the receiver *d* is a tube of safety *h*. The receivers are placed on a stand a little inclined, and kept steady by slips of wood hollowed out to fit their curvatures, as represented at *s s*. This apparatus requires no lute; has no bent tubes that are difficult to adjust, and liable to break; and the retort may be removed at any stage of the process, either to find the weight it has lost, or for any other purpose, the receiver being meanwhile closed with the stopple.

Fig. 3 represents the different parts of the apparatus required for measuring the quantity of elastic fluid given out during the action of an acid on calcareous soils. The bottle for containing the soil is represented at *a*; *b* the bottle containing the acid, furnished with a stop-cock; *c* the tube connected with a flaccid bladder *d*; *f* a graduated measure; *e* the bottle for containing the bladder. When this instrument is used, a given quantity of soil is introduced into *a*: *b* is filled with muriatic acid, diluted with an equal quantity of water; and the stop-cock, being closed, is connected with the upper orifice of *a*, which is ground to receive it. The tube *c* is introduced into the lower orifice of *a*, and the bladder connected with it placed in its flaccid state in *e*, which is filled with water. The graduated measure is placed under the tube of *e*. When the stop-cock of *b* is turned, the acid flows into *a*, and acts upon the soil; the elastic fluid generated passes through *c* into the bladder, and displaces a quantity of water in *e*, equal to it in bulk; and this water flows through the tube into the graduated measure, the water in which gives, by its volume, the indication of the proportion of carbonic acid disengaged from the soil.

In chemical experiments the blow-pipe is of essential utility. This instrument is now variously constructed. The blow-pipe for philosophical purposes is provided with a bowl, or enlargement. *a*, fig. 7, in which the vapours of the breath are condensed and detained; and also with three or four small nozzles, *b*, with different apertures, to be slipped on the smaller extremity.

A wax candle, of a moderate size, but thicker wick than they are usually made with, is the most convenient for occasional experiments; but a tallow candle will do very well. The candle should be snuffed rather short, and the wick turned on one side toward the object, so that a part of it should lie horizontally. The stream of air must be blown along this horizontal part, as near as may be without striking the wick. When the hole is of a proper figure, and duly proportioned, the flame consists of a neat luminous blue cone, surrounded by another flame of a more faint and indistinct appearance. The strongest heat is at the point of the inner flame.

The body intended to be acted on by the blow-pipe, ought not to exceed the size of a peppercorn. It may be laid upon a piece of close-grained, well-burned charcoal unless it be of such a nature as to sink into the pores of this substance, or to have its properties affected by its inflammable quality. Such bodies may be placed in a small spoon made of pure gold, or silver, or platina.

A very ingenious contrivance by Mr. Hooke, sometimes called the self-acting blow-pipe, is represented, plate XXIV. fig. 15. Here, *a* is a hollow sphere for containing alcohol, resting upon a shoulder in the ring *o*. If the bottom be made flat instead of spherical, the action of the flame will then be greater. *b* is a bent tube with a jet at the end, to convey the alcohol in the state of a vapour into the flame at *q*. This tube is continued in the inside up to *c*, which admits of *a* being filled nearly, without any alcohol running over. *d* is a safety valve, the pressure of which is determined at pleasure, by screwing higher or lower on the pillar , the two milled nuts *f* and *g* carrying the steel arm *h*, which rests on the valve. *i* is an opening for putting in the alcohol. *k* is the lamp. which adjusts to different distances from *a*, by sliding up or down the two pillars *l l*. The distance of the flame *q* from the jet is regulated by the pipe which holds the wick being a little removed from the centre of the brass piece *m*, and of course revolving in a circle. *n* the mahogany stand.

The greatest improvement, however, that this instrument has undergone, was introduced by Mr. Gurney, in his lectures delivered at the Surrey Institution, of which a full account may be seen in the published volume.

For distillation on a small scale, the retort or the alembic may be employed; but for many purposes it is necessary to use a still constructed on the principle of those which are made of the largest dimensions.

Fig. 16 represents the large stills used in the distillation of ardent spirits. *a* represents the body, and *b* the head, as before. Instead of using a refrigeratory or receiver, the spirit is made to pass through a spiral pipe called the worm, which is immersed in a tub of cold water *d*. During its passage it is condensed, and comes out at the lower extremity *e*, of the pipe, in a fluid form.

An indispensable article of apparatus in the laboratory is the gasometer, which enables the operator to receive and preserve large quantities of gas, with the aid of only a few pounds of water. Gasometers are made of different forms; but one of the most simple and most convenient, is shewn in fig. 4. plate XXV. It consists of an outer fixed vessel, *d*, and an inner fixed one, *c*, both of japanned iron. The inner vessel slides easily up and down within the outer, and is suspended by cords passing over pullies: to which are attached the counterpoises *e e*. To avoid the inconvenience of a great weight of water, the outer vessel is made double, or is composed of two cylinders, the inner of which is closed at the top and at the bottom.

The space only of about half an inch is left between the two cylinders as shown by the dotted lines. In this space the vessel *c*, may move freely up and down. The interval is filled with water as high as the top of the inner cylinder. The cup or rim on the top of the outer vessel, is to prevent the water from overflowing when the vessel *c* is forcibly pressed down, in which situation it is placed whenever gas is about to be collected. The gas enters from the vessel in which it is produced by the communicating opening *b*, and passes along the perpendicular pipe marked by dotted lines in the centre into the cavity of the vessel *c*, which continues rising till it is full.

To transfer the gas, or to apply it to any purpose, the cock *b* is to be shut, and an empty bladder, or bottle of elastic gum, furnished with a stop cock, is to be screwed on *a*. When the vessel *c* is pressed down by the hand, the gas passes down the central pipe, which it had before ascended, and its escape at *b* being prevented, it finds its way up a pipe which is fixed on the outer surface of the vessel, and which is terminated by the cock *a*. By means of an ivory mouth-piece screwed on this cock, the gas included in the instrument may be respired; the nostrils being closed by the fingers. When it is required to transfer the gas into glass jars standing in water, a crooked tube may be employed, one end of which is screwed upon the cock, *b*, while the other aperture is brought under the inverted funnel, fixed into the shelf of the pneumatic trough. The counterpoises *e e*, are generally concealed in the framing, and the vessel *c* is frequently made of glass.

When large quantities of gas are required (as at a public lecture) the gas holder, fig. 5. will be found extremely useful. It is made of tinned iron plate, japanned both within and without. Two short pipes, *a* and *c*, terminated by cocks, proceed from its sides, and another, *b*, passes through the middle of the top or cover, to which it is soldered, and reaches within half an inch of the bottom.

It will be found convenient also to have an air cock with a very wide bore fixed to the funnel at *b*. When gas is to be transferred into this vessel from the gasometer, the vessel is first completely filled with water through the funnel, the cock *a* being left open and *c* shut. By means of an horizontal pipe, the aperture *a* is connected with *a* of the gasometer. The cock *b* being shut, *a* and *c* are opened, and the vessel *c* of the gasometer, fig. 8, gently pressed downwards with the hand. The gas then descends from the gasometer till the air holder is full; which may be known by the water ceasing to escape through the cock *c*. All the cocks are then to be shut, and the vessels disunited. To apply this gas to any purpose, an empty bladder may be screwed on *a*. And water being poured through the funnel *b*, a corresponding quantity of gas is forced into the bladder. By lengthening the pipe *b*, the pressure of a column of water may be added; and the gas being forced through *a*, with considerable velocity, may be applied to the purpose of a blow-pipe, &c. &c.

Fig. 8 represents the combustion of iron-wire in oxygen gas. If a fine iron-wire, *a*, twisted in the form of a cork screw, having an ignited sulphur match attached to it, be plunged into a jar of oxygen gas, *b*, a most brilliant and rapid scintillating combustion takes place, forming oxide of iron. In this process, such is the greatness of the heat, that the small globules of the melted metal often penetrate the sides of the jar, if permitted to strike against them.

We shall conclude this article with a remark or two respecting furnaces, which, perhaps, would have been better introduced before; but it is hoped that this circumstance will be viewed as of minor importance.

The best construction of a furnace has not been well ascertained from experience. There are facts which shew, that a fire made on a grate near the bottom of a chimney, of equal width throughout, and open both above and below, will produce a more intense heat than any other furnace. What may be the limits for the height of the chimney is not ascertained from any precise trials; but thirty times its diameter would not probably be too high. It seems to be an advantage to contract the diameter of a chimney, so as to make it smaller than that of the fire-place, when no other air is to go up the chimney than what has passed through the fire; and there is no prospect of advantage to be derived from widening it.

Fig. 9 exhibits the wind or air furnace for melting. *a* is the ash-hole, *f* an opening for the air. *c* is the fire-place, containing a covered crucible, standing on a support of baked earth, which rests on the grate; *d* is the passage into *e*, the chimney. At *d* a shallow crucible or cupel may be placed in the current of the flame, and at *x* is an earthen or stone cover, to be occasionally taken off for the purpose of supplying the fire with fuel.

Fig. 10 is [illegible] reverberatory furnace [illegible] the ash-pit and fire place. *b b* body of the furnace. *c c* dome, or reverberating roof of the furnace. *d d* chimney. *e e* door of the ash-pit. *f f* door of the fire-place. *g g* handles of the body. *h* aperture to admit the head of the retort. *i i* handles of the dome. *k* receiver *l l* stand of the receiver. *m m* retort, represented in the body by dotted lines.

M. Chenevix has constructed a wind furnace, which is in some respects to be preferred to the usual form. The sides, instead of being perpendicular, are inverted, so that the hollow space is pyramidical. At the bottom the opening is 13 inches square, and at the top but eight. The perpendicular height is 17 inches. This form appears to unite the following advantages:—1st, A great surface is exposed to the air, which, having an easy entrance, rushes through the fuel with great rapidity; 2d, The inclined sides act in some measure as reverberating surfaces; and 3d, The fuel falls of itself, and is always in close contact with the crucible placed near the grate. The late Dr. Kennedy of Edinburgh, whose opinion on this subject claims the greatest weight, found that the strongest heat in our common wind furnaces was within two or three inches of the grate. This, therefore, is the most advantageous position for the crucible, and still more so when we can keep it surrounded with fuel. It is inconvenient and dangerous for the crucible, to stir the fire often to make the fuel fall, and the pyramidical form renders this unnecessary.

Many other articles of apparatus might have been here enumerated; but if the student find the above insufficient for his purpose, let him consult those works which treat exclusively on chemistry. We shall only here add that no laboratory can be complete without a very powerful electrical machine, and a good double barrelled air-pump.

Laboratory, signifies also in military affairs, that place where all sorts of fire-works are prepared both for actual service, and for pleasure.

LABOUR, in general, denotes a close application to work or business. Among seamen a ship is said to be in labour when she rolls and tumbles very much, either a hull under sail, or at anchor. It is also spoke of a woman in travail, or child-birth.

LABOURER. See Master and Servant.

LABRADOR *stone*. See Felspar.

LABYRINTH, in gardening, a winding mazy walk between hedges, through a wood or wilderness. The chief aim is to make the walks so perplexed and intricate, that a person may lose himself in them, and meet with as great a number of disappointments as possible. They are rarely to be met with, except in great gardens, as Versailles, Hampton-court, &c.

The few celebrated labyrinths of the ancients were those of Crete, Egypt, Lemnos, and Italy.

LAC is a substance well known in Europe, under the different appellations of stick-lac, shell-lac, and seed-lac. The first is the lac in its natural state, encrusting small branches or twigs. Seed-lac is the stick-lac separated from the twigs, appearing in a granulated form, and probably deprived of part of its colouring matter by boiling. Shell-lac is the substance which has undergone a simple purification, as mentioned below. Besides these we sometimes meet with a fourth, called lump-lac, which is the seed-lac melted and formed into cakes.

Lac is the product of the coccus lacca, which deposits its eggs on the branches of a tree called Bihar, in Assam, a country bordering on Thibet, and elsewhere in India. It appears designed to answer the purpose of defending the eggs from injury, and affording food for the maggot in a more advanced state. It is formed into cells, finished with as much art and regularity as a honeycomb, but differently arranged; and the inhabitants collect it twice a-year, in the months of February and August.

For the purification, it is broken into small pieces, and put into a canvass bag of about four feet long, and not above six inches in circumference. In India, lac is fashioned into rings, beads, and other trinkets; sealing-wax, varnishes, and lakes for painters, are made from it; it is much used as a red dye, and wool tinged with it is employed as a fucus by the ladies; and the resinous part, melted and mixed with about thrice its weight of finely powdered sand, forms polishing stones. The lapidaries mix powder of corundum with it in a similar manner.

LACCIC *acid*, in chemistry, a white or yellowish production of insects, called white-lac. Some of this substance, brought from Madras, was analyzed by Dr. Pearson, who found that it bore a considerable analogy to bees wax. The component parts of this acid are supposed to be carbon, hydrogen, and oxygen.

LACE, in commerce, a work composed of many threads of gold, silver, or silk, interwoven one with the other, and worked upon a pillow with spindles, according to the pattern designed; the open work being formed with pins, which are placed and displaced as the spindles are moved.

Method of cleaning gold-lace and embroidery when tarnished.—For this purpose alkaline liquors are by no means to be used; for while they clean the gold they corrode the silk, and change or discharge its colour. Soap also alters the shade, and even the species of certain colours. But spirit of wine may be used without any danger of its injuring either the colour or quality of the subject; and in many cases proves as effectual for restoring the lustre of the gold as the corrosive detergents.

Lace, *bone*, a lace made on fine linen thread or silk, much in the same manner as that of gold and silver. The pattern of the lace is fixed upon a large round pillow, and pins being stuck into the holes or openings in the pattern, the threads are interwoven by means of a number of bobbins, made of bone or ivory, each of which contains a small quantity of fine thread, in such a manner as to make the lace exactly resemble the pattern.

LACERTA, *lizard*, a genus of the amphibia class, and of the order of reptiles; the generic character is, body four-footed, elongated, tailed; without any secondary integument. Of this genus there are reckoned about eighty species, of which we can here notice only a few of the most remarkable:

1. *Lacerta crocodilus*, or crocodile. The crocodile, so remarkable for its size and powers of destruction, is a native of Asia and Africa, but seems to be most common in the latter; inhabiting large rivers, as the Nile, the Niger, &c. and preying principally on fish, but occasionally seizing on almost every animal which happens to be exposed to its rapacity. The size to which the crocodile sometimes arrives is prodigious: specimens being frequently

seen of 20 feet in length, and instances are commemorated of some which have exceeded the length of 30 feet. The armour with which the upper part of the body is covered may be numbered among the most elaborate pieces of nature's mechanism. In the full grown animal it is so strong and thick as easily to repel a musket-ball; on the lower parts it is much thinner, and of a more pliable nature: the whole animal appears as if covered with the most regular and curious carved work; the colour of a full grown crocodile is blackish-brown above, and yellowish-white beneath; the upper parts of the legs and the sides varied with deep yellow, and in some parts tinged with green.

The crocodile in a young state is by no means to be dreaded, its small size and weakness preventing it from being able to injure any of the larger animals: it therefore contents itself with fish and other small prey. The crocodile lies in wait near the banks, and snatches dogs and other animals, swallowing them instantly, and then plunging into the flood, and seeking some retired part, where it may lie concealed till hunger again invites it to its prey. In its manner of attack it is exactly imitated by the common lacerta palustris, or water-newt, which, though not more than four or five inches long, will with the greatest ease swallow an insect of more than an inch in length; and that at one single effort, and with a motion so quick, that the eye can scarcely follow it.

Crocodiles. like the rest of the lacertæ, are oviparous: they deposit their eggs in the sand or mud near or on the banks of the rivers they frequent, and the young when hatched immediately proceed to the water; but the major part are said to be devoured by other animals, as ichneumons, birds, &c. The eggs, as well as the flesh of the crocodile itself, are numbered among the delicacies of some of the African nations, and are said to form one of their favorite repasts.

2. *Lacerta alligator* so nearly resembles the crocodile, that many naturalists have been inclined to consider it as a mere variety, rather than a distinct species. The leading difference seems to be, that the head of the alligator is rather smooth on the upper part than marked with those very strong rugosities and hard carinated scales which appear on that of the crocodile; and that the snout is considerably flatter and wider, as well as more rounded at the extremity. The alligator arrives at a size not much inferior to that of the crocodile.

3. *Lacerta Gangetica.* The Gangetic crocodile is so strikingly distinguished both from the Nilotic and the alligator by the peculiar form of the mouth, that it is hardly possible, to confound it with either of the former; the jaws being remarkably long, narrow, and perfectly straight, and the upper mandible terminated above an elevated tubercle. The teeth are nearly double the number of those of the common crocodile, and are of equal size throughout the whole length of the jaws. This species is a native of India, and is principally seen in the Ganges.

4. *Lacerta iguana* is a native of many parts of America and the West Indian islands, and is also said to occur in some parts of the East Indies. Its general colour is green, but with much variation in the tinge of different individuals: it is generally shaded with brown in some parts of the body, and sometimes this is even the predominating colour. The back of the guana is very strongly serrated; and this, together with the gular pouch, which it has the power of extending or inflating occasionally to a great degree, gives a formidable appearance to an animal otherwise harmless. It inhabits rocky and woody places, and feeds on insects and vegetables. It is itself reckoned an excellent food, being extremely nourishing and delicate; but it is observed to disagree with some constitutions. The guana may be easily tamed while young, and is both an innocent and beautiful creature in that state.

5. *Lacerta basiliscus.* The basilisk of the ancients, supposed to be the most malignant of all poisonous animals, and of which the very aspect was said to be fatal, is a fabulous existence to be found only in the representations of painters and poets. But the animal known in modern natural history by this name is a species of lizard, of a very singular shape, and which is particularly distinguished by a long and broad wing-like process continued along the whole length of the back, and to a considerable distance on the upper part of the tail, and furnished at certain distances with internal radii analogous to those in the fins of fishes, and still more so to those in the wings of the draco volans, or flying lizard. Notwithstanding its formidable appearance the basilisk is a perfectly harmless animal, and, like many other of the lizard tribe, resides principally among trees, where it feeds on insects, &c.

6. *Lacerta chamæleon.* Few animals have been more celebrated by natural historians than the chameleon, which has been sometimes said to possess the power of changing its colour at pleasure, and of assimilating it to that of any particular object or situation. This, however, must be received with very great limitations; the change of colour which the animal exhibits varying in degree according to circumstances of health, temperature of the weather, and many other causes, and consisting chiefly in a sort of alteration of shades from the natural greenish or bluish grey of the skin into pale yellowish, with irregular spots or patches of dull red. The general length of the chameleon, from the tip of the nose to the beginning of the tail, is about ten inches, and the tail is of nearly similar length, but the animal is found of various sizes, and sometimes exceeds the length above mentioned. It is a creature of a harmless nature, and supports itself by feeding on insects; for which purpose the structure of the tongue is finely adapted, consisting of a long, missile body, furnished with a dilated and somewhat tubular tip, by means of which the animal seizes insects with great ease, darting out its tongue in the manner of a woodpecker, and retracting it instantaneously with the prey secured on its tip. It can also support a long abstinence, and hence arose the popular idea of the chameleon being nourished by air alone. It is found in many parts of the world, and particularly in India and Africa.

7. *Lacerta salamandra.* The salamander, so long the subject of popular error, and of which so many idle tales have been recited, is an inhabitant of many parts of Germany, Italy, France, &c. but does not appear to have been discovered in England. It delights in moist

and shady places, woods, &c. and is chiefly seen during a rainy season. In the winter it lies concealed in the hollows about the roots of old trees, in subterraneous recesses, or in the cavities of old walls, &c The idea of its being capable of enduring fire without injury, can be accounted for, merely from its possessing a power of exuding in any state of irritation a white and glutinous substance, which must of course tend to render the application of fire less immediately destructive to it than to some other animals, and considering what trifling causes have led, in innumerable cases to important inferences, this fact may probably have given rise to the notion of the salamander being insusceptible of destruction, and even of injury in the midst of flames. The idea of its poisoning any large animal by its bite is equally exploded. The salamander produces its young living, hatched from internal eggs, and frequently upwards of thirty in number.

8. *Lacerta vulgaris.* This, which is the smallest of the British lizards, is altogether a terrestrial species. It is commonly seen in gardens, and not unfrequently in the neighbourhood of dunghills, &c. It also occasionally makes its way into cellars in the manner of the slug, the toad, &c.

9. *Lacerta aquatica.* This, which in England occurs almost in every stagnant water, is a small species. Its general length is about three inches and a half, and it very rarely exceeds that of four inches at most. The water-newts are remarkable for a high degree of reproductive power, and have been known to exhibit the restoration of their legs, tails, and even, according to Dr. Blumenbach, of the eyes themselves, after having been deprived of them by cutting.

LACHES, in law, signifies slackness or negligence; as when we say, "there is a laches of entry," it means the same as to say, there is lack or neglect of entry.

LACHRYMAL, in anatomy, an appellation given to several parts of the eye, from their serving to secrete the tears. The lachrymal gland is situated in the orbit above the smaller angle, and its excretory ducts under the upper eye-lid.

LACK *of rupees*, is 100,000 rupees; which, supposing them standard, or siccas, at 2*s.* 6*d.* amounts to 12,500*l.* sterling.

LACQUERS, are varnishes applied upon tin, brass, and other metals, to preserve them from tarnishing, and to improve their colour. The basis of lacquers is a solution of the resinous substances called seed lac in spirit of wine. The spirit ought to be very much concentrated, in order to dissolve much of the lac. To a pint of the purified spirit, about three ounces of powdered shell-lac are to be added; and the mixture to be digested during the same day with a moderate heat. The liquor ought then to be poured off, strained, and cleared by settling. This clear liquor is now fit to receive the required colour from certain resinous colouring substances, the principal of which are gamboge and annotto; the former of which gives a yellow, and the latter an orange colour. In order to give a golden colour, two parts of gamboge are added to one of annotto; but these colouring substances may be separately dissolved in the tincture of lac, and the colour required may be adjusted by mixing the two solutions in different proportions. When silver leaf or tin is to be lacquered, a larger quantity of the colouring materials is requisite than when the lacquer is intended to be laid on brass.

LACTEAL *vessels*. See ANATOMY.

LACTIC *acid*. By evaporating sour whey to one-eighth, filtering, precipitating with lime water, and separating the lime by oxalic acid, Scheele obtained an aqueous solution of what he supposed to be a peculiar acid, which has accordingly been termed the *lactic*. To procure it separate, he evaporated the solution to the consistence of honey, poured on it alcohol, filtered this solution, and evaporated the alcohol. The residuum was an acid of a yellow colour, incapable of being crystallized, attracting the humidity of the air, and forming deliquescent salts with the earths and alkalis.

Bouillon Lagrange since examined it more narrowly; and from a series of experiments concluded, that it consists of acetic acid, muriate of potash, a small portion of iron probably dissolved in the acetic acid, and an animal matter.

This judgment of M. Lagrange was afterwards supported by the opinions of MM. Fourcroy and Vauquelin. But since then Berzelius has investigated its nature very fully, and has obtained, by means of a long and often repeated series of different experiments, a complete conviction that Scheele was in the right, and that the lactic acid is a peculiar acid, very distinct from all others. The extract which is obtained when dried whey is digested with alcohol, contains uncombined lactic acid, lactate of potash, muriate of potash, and a proper animal matter.

LACTUCA, the *lettuce*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. There are 11 species, most of which are plants of no use, and never cultivated but in botanic gardens for variety. That commonly cultivated in the kitchen-garden is the sativa, which includes the following varieties: 1. The common or garden lettuce. 2. Cabbage lettuce. 3. Silesia lettuce. 4 Dutch brown lettuce. 5. Aleppo, or sperm lettuce. 6. Imperial lettuce. 7. Green capuchin lettuce. 8. Versailles, or upright white cos lettuce 9. Black cos. 10. Red cos. 11. Red capuchin lettuce. 12. Roman lettuce. 13. Prince lettuce. 14. Royal lettuce. 15. Egyptian cos lettuce.

LADDERS, *scaling*, in the military art, are used in scaling when a place is to be taken by surprise. They are made several ways. Sometimes of flat staves, so that they may move about their pins, and shut like a parallel ruler, for conveniently carrying them: the French make them of several pieces, so as to be joined together, and to be made of any necessary length: sometimes they are made of single ropes, knotted at proper distances, with iron hooks at each end, one to fasten them upon the wall above, and the other in the ground; and sometimes they are made with two ropes, and staves between them, to keep the ropes at a proper distance, and to tread upon. When they are used in the action of scaling walls, they ought to be rather too long than too short, and to be given in charge only to the stoutest of the detachment.

LADY'S *smock*. See CARDEMINE.

Lady's *slipper*. See Cypripedium.

LAETIA, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. There are four species, natives of America. One of them, the apetala, or gum-wood, Dr. Wright informs us, is very common in the woodlands and copses of Jamaica, where it rises to a considerable height and thickness.

LAGOECIA, a genus of the monogynia order, in the pentandria class of plants. There is one species, wild cummin, an annual of the Levant.

LAGUNEA, a genus of the class and order monadelphia polyandria. There are three species, shrubs of the East Indies and Surinam.

LAGURUS, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the fourth order gramina. There is one species, a grass of the south of Europe.

LAKE, a collection of waters contained in some cavity in an inland place, of a large extent, surrounded by land, and having no visible connexion with the ocean. Geographers divide lakes into four kinds. 1. Such as neither receive nor send forth rivers. 2. Such as send forth rivers, without receiving any. 3. Such as receive rivers without emitting any. And, 4. Such as both receive and send forth rivers. See Geography.

Lake, is a combination of colouring extract, with an earth, or metallic oxide, formed by precipitation from the solution of the colouring matter. If a solution of alum is added to an infusion of madder, a mutual decomposition takes place, and part of the alumine falls united with the colouring matter of the madder. Precipitates, of different shades of colour, are obtained with alum, nitre, chalk, acetate of lead, and muriate of tin. The lakes form some of the beautiful pigments, and are highly esteemed in water-colour painting.

LAMA, the sovereign pontiff, or rather god, of the Asiatic Tartars, inhabiting the country of Barantola. The Lama is not only adored by the inhabitants of the country, but also by the kings of Tartary, who send him rich presents, and go in pilgrimage to pay him adoration, calling him lama-congin, *i. e.* God the everlasting father of heaven. He is never to be seen but in a secret place of his palace, amidst a great number of lamps, sitting cross-legged upon a cushion, and adorned all over with gold and precious stones: where, at a distance, they prostrate themselves before him, it not being lawful for any to kiss even his feet.

LAMB. See Ovis.

LAMINÆ, the thin plates of which any thing consists: hence the epithet laminated, which is applied to those bodies, the texture of which discovers such a disposition as that of plates lying over one another.

LAMIUM, *dead-nettle*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. There are 13 species, of which only two, viz. the album, white archangel or dead-nettle, and the purpureum, or red archangel, deserve notice.

LAMP, a vessel containing oil, with a lighted wick; of which there is an indefinite number made of various constructions for various purposes. We shall particularly notice Argand's lamp. The principle on which the superiority of this lamp depends, is the admission of a larger quantity of air to the flame than can be done in the common way. This is accomplished by making the wick of a circular form, by which means the current of air rushes through the cylinder on which it is placed, and along with that which has access to the outside, excites the flame to such a degree that the smoke is entirely consumed. Thus, both the light and heat are much increased, at the same time that there is a considerable saving in the expence of oil, the consumption of the inflammable matter being exceedingly augmented by the quantity of air admitted to the flame; so that what in common lamps is dissipated in smoke is here converted into a brilliant flame. This lamp is now very much in use, and is consequently well known.

Various improvements have been made on the construction of Argand's lamp, but to the present hour the principle remains the same. Almost all the modern gas burners are on Argand's principle; and indeed the most splendid and costly modern lamps, whether French or English, give out their light from an Argand burner.

The chief improvement in the Argand lamp is, the method of raising and depressing the wick: this was formerly done by means of a rack and pinion, but these motions are now produced by means of a single tooth working in a spiral groove cut on the outside of a tube, within which is placed the wick, stretched tightly over a brass ring, or rather short tube, which is jagged to keep the wick tight.

We shall here notice a very curious, and what in many cases must be a very useful lamp, viz. a *lamp without flame*. To construct a lamp of this description, take a fine platinum wire, about $\frac{1}{100}$ of an inch in diameter; form with it about a dozen convolutions on a tobacco-pipe or a small black lead pencil: place this spiral on the tube of a common spirit lamp; let the lamp be half filled with spirit; light the wick, and when the coils of the wire become red-hot, blow out the flame, and all the wire above the wick will quickly become of a white heat, and continue to give out a very brilliant light as long as the alcohol lasts. The experiment, however, requires great delicacy to make it succeed.

Lamp-*black*. See Black.

LAMPREY. See Petromyzon.

LAMPYRIS, *glow-worm*, a genus of insects of the order coleoptera: the generic character is, antennæ filiform; wing-sheaths flexile; thorax flat, semiorbicular, concealing and surrounding the head; abdomen with the sides pleated into papillæ; female (in most species) wingless. The lampyris noctiluca, or common glow-worm, is a highly curious and interesting animal. It is seen during the summer months as late as the close of August, if the season is mild, on dry banks, about wood, pastures, and hedgeways, exhibiting, as soon as the dusk of the evening commences, the most vivid and beautiful phosphoric splendour, in form of a round spot of considerable size. The animal itself, which is the female insect, measures about three quarters of an inch in length, and is of a dull earthy brown colour on the upper parts, and beneath more or less tinged with

ose-colour, with the two or three last joints of the body of a pale or whitish sulphur colour. The glow-worm is a slow-moving insect, and in its manner of walking frequently seems to drag itself on by starts, or slight efforts.

LANA, in botany, *wool*, a species of pubescence, down, or velvet, which serves to screen the leaves, covered with it, from the heat: this appearance is very conspicuous in the horehound, woolly thistle, &c.

LANA *philosophica*, flowers of zinc. See ZINC.

LANCET, a chirurgical instrument, sharp-pointed, and two-edged, chiefly used for opening veins in the operation of phlebotomy, or bleeding; also for laying open abscesses, tumours, &c.

LAND, in the sea language, makes part of several compound terms: thus *land-laid*, or to lay the land, is just to lose sight of it. *Land-locked*, is when the land lies all round the ship, so that no point of the compass is open to the sea: if she is at anchor in such a place, she is said to ride land-locked, and is therefore concluded to ride safe from the violence of winds and tides. *Land-mark*, any mountain, rock, steeple, tree, &c. that may serve to make the land known at sea. *Land is shut in*, a term used to signify that another point of land hinders the sight of that the ship came from. *Land to*, or the ship lies land to, that is, she is so far from shore that it can only be just discerned. *Land-turn*, is a wind that in almost all hot countries blows at certain times from the shore in the night. *To set the land*, that is, to see by the compass how it bears.

LANDSCAPE. See PAINTING.

LANGUAGE, properly signifies the expression or enunciation of human thoughts and sentiments, by means of the articulate sounds of the human voice.

Man, of all animals, only is possessed of speech. Mere sound is, indeed, the sign of what is pleasurable or painful, and it is, for that reason, common to most other animals; for, in this manner, do they signify their feelings to each other. But speech indicates what is expedient or hurtful, and, a natural consequence, what is just or unjust. It is, therefore, given to man; for a sense of good and evil is peculiar to man alone.

The most intelligent of the brute creation frequently astonish us by actions, which can proceed only from powers of intellect, similar to our own: the capacity of speech then, is the criterion of distinction between man and the brute creation. Reason, the capital faculty and characteristic of man, would, without this extensive power of communication, have remained in inactivity, its energies unexcited, and its faculties torpid. The origin of written language is involved in great obscurity; nor has this obscurity been much lessened by the erudition that has been expended in the attempts of the learned to remove it. In the early ages of the world, there is every reason to suppose, that the difference of language in Europe, Asia, and Africa, was no more than a difference of dialects; and that the people of Greece, of Phœnicia, and of Egypt, mutually understood each other. The *oriental* origin of the Latin and Greek, is now generally acknowledged; and to these the Teutonic dialects have an affinity; the Arabic, the Chaldee, the Syriac, and the Ethiopic still bear the most striking resemblance to the *Hebrew*: in the Welsh, are many words analogous to it: the Celtic, also, has derived much from this and other eastern languages. The Hebrew, then, if we judge from these remarkable facts, from the mode of its derivation from its radicals, or from the simplicity of its structure must, undoubtedly, be considered as the primitive or parent language.

An eminent linguist of the present day thinks it very likely, that the original language was composed of monosyllables, that each had a distinct ideal meaning, and only one meaning; as different acceptations of the word would undoubtedly arise, either from compounding terms, or when there were but few words in the language, using them by a different mode of pronunciation, to express a variety of things. Where this simple, monosyllabic language prevailed, (and it must have prevailed in the first ages of the world,) men would necessarily have *simple ideas*, and a corresponding *simplicity of manners*. The Chinese language is exactly such as this; and the Hebrew, if stripped of its vowel points, and its prefixes, suffixes, and postfixes, separated from their combinations, so that they might stand by themselves, would nearly answer to this character, even in its present state.

LANIUS, the *shrike* or *butcher-bird*; a genus belonging to the order of accipitres; generic character, beak somewhat straight, with a tooth on each side towards the apex, and naked at the base; tongue lacerated.

1. The *excubitor*, great cinereous shrike, or greater butcher-bird, is in length ten inches. The plumage on the upper parts is of a pale ash-colour; the under, white; through the eyes there is a black stripe; the scapulars are white; the base of the greater quills is white, the rest black. It feeds on small birds, young nestlings, beetles, and caterpillars. When it has killed the prey, it fixes them on some thorn, and when thus spitted, pulls them to pieces with its bill. When confined in a cage they will often treat their food in much the same manner, sticking it against the wires before they devour it. This bird inhabits many parts of Europe and North America. The female makes its nest with heath and moss, lining it with wool and gossamer, and lays six eggs, about the size of those of a thrush, of a dull olive-green, spotted at the thickest end with black. In countries where they are plenty, the husbandmen value them, on supposition of their destroying rats, mice, and other vermin.

2. The *collurio*, or lesser butcher-bird, is seven inches and a half in length. This bird is much more common than the former species. It lays six white eggs, marked with a rufous brown circle towards the large end. The nest is generally in a hedge or low bush, near which, it is said no small bird chooses to build; for it not only feeds on insects, but also on the young of other birds in the nest, taking hold of them by the neck, and strangling them, beginning to eat them first at the brain and eyes.

3. The *infaustus*, or rock shrike, is in length seven inches and three quarters. The bill is about an inch long, and blackish; the head and neck are of a dark ash-colour, marked with small rufous spots; the upper part of the back is a dark brown; the lower much

paler, especially towards the tail; the quills and wing-coverts are dusky, with pale margins; the breast, and under parts of the body are orange, marked with small spots, some white and others brown. This species is met with in many parts of Europe, from Italy to Russia, and is found in some parts of Germany.

4. The *faustus*, or white-wreathed shrike, is about the size of a common thrush. Its bill is pale; the upper parts of the body are grey; the under ferruginous; from the eyes to the hind head there passes a whitish line, composed of numerous white feathers; rendering it truly characteristic. This elegant species inhabits China, where it is known by the name of whommaj.

5. The *tyrannus*, or tyrant shrike, is about the size of a thrush. Its bill is a blackish brown, beset with bristles at the base; the irides are brown; the upper parts of the plumage grey brown; the under white; the breast inclines to ash-colour; the head is blackish on the upper part; the base of the feathers on that part in the male is orange, but seldom visible except it erects the feathers, when there appears a streak of orange down the middle of the crown. It inhabits Virginia. There is a variety which inhabits St. Domingo and Jamaica. All authors agree in the manners of these birds, which are ferocious to a great degree; while the hen is sitting, no bird whatever dare approach their nest; they will attack the first which comes near, without reserve, and usually come off conquerors.

LANTERN, *magic*, an optical machine, whereby little painted images are represented so much magnified, as to be accounted the effect of magic by the ignorant. See OPTICS.

LANTERN. See ARCHITECTURE.

LAPIDARY. There are various machines employed in the cutting of precious stones, according to the quality. The diamond, which is extremely hard, is cut on a wheel of soft steel, turned by a mill, with diamond dust, tempered with olive-oil, which also serves to polish it. The oriental ruby, sapphire, and topaz, are cut on a copper wheel with diamond dust, tempered with olive oil, and are polished on another copper wheel with tripoli and water. The hyacinth, emerald, amethyst, garnets, agates, and other stones, not of an equal degree of hardness with the other, are cut on a leaden wheel with smalt and water, and polished on a tin wheel with tripoli.

LAPIS, in general, is used to denote a stone of any kind. See MINERALOGY.

LAPLISIA, in natural history, *sea-hare*, a genus of the vermes mollusca class and order. Body creeping, covered with reflected membranes, with a membranaceous shield on the back, covering the lungs; aperture placed on the right side; vent above the extremity of the back; four feelers, resembling ears. There are two species; viz. L. depilans; body pale lead colour; immaculate. It inhabits the European seas; from two to five inches long; is extremely nauseous and fetid, and is said to cause the hair to fall off from the hands of those who touch it. L. faciata, black; the edges of the membranaceous covering, and of the feelers scarlet; it inhabits the shores of Barbary, among rocks, and is frequently to be met with off Anglesea

LAPSED *legacy*, is where the legatee dies before the testator; or where a legacy is given upon a future contingency, and the legatee dies before the contingency happens.

LARBOARD, among seamen, the left hand side of the ship, when you stand with your face towards the head.

LARCENY, is the felonious and fraudulent taking away of the personal goods of another; which goods, if they are above the value of 12*d.* it is called grand larceny; if of that value or under, it is petit larceny; which two species are distinguished in their punishment, but not otherwise. The mind only makes the taking of another's goods to be felony, or a bare trespass only.

As all felony includes trespass, every indictment must have the words feloniously took, as well as carried away; whence it follows, that if the party be guilty of no trespass in taking the goods, he cannot be guilty of felony in carrying them away. With respect to what shall be considered a sufficient carrying away, to constitute the offence of larceny; it seems that the least removing of the thing taken, from the place where it was before, is sufficient for this purpose, though it be not quite carried off.

Larceny from the person.—If larceny from the person be done privately without his knowledge, by picking of pockets or otherwise, it is excluded from the benefit of clergy by 8 Eliz. c. 4. provided the thing stolen be above the value of 12*d.* But if done openly, and avowedly before his face, it is within the benefit of clergy.

Larceny from the house.—Every person who shall be convicted of the feloniously taking away in the day time, any money or goods of the value of 5*s.* in any dwelling-house, or outhouse thereunto belonging, and used to and with the same, though no person be therein, shall be guilty of felony, without the benefit of clergy.

Receiving stolen goods.—Any person who shall buy or receive any stolen goods, knowing them to be stolen; or shall receive, harbour, or conceal any felons or thieves, knowing them to be so; shall be deemed accessary to the felony: and being convicted on the testimony of one witness, shall suffer death as a felon convict; but he shall be entitled to his clergy.

Any person convicted of receiving or buying stolen goods, knowing them to be stolen, may be transported for fourteen years.

Every person who shall apprehend any one guilty of breaking open houses in a felonious manner, or of privately and feloniously stealing goods, wares, or merchandizes, of the value of 5*s.* in any shop, ware-house, coach-house, or stable, though it is not broken open, and though no person is therein to be put in fear, and shall prosecute him to conviction, shall have a certificate without fee, under the hand of the judge, certifying such conviction, and within what parish or place the felony was committed, and also that such felon was discovered and taken.

LARK. See ALAUDA.

LARKSPUR. See DELPHINIUM.

LARVA, in natural history, a name given by Linnæus to insects in that state, called by other writers eruca, or caterpillar.

LARUS, *the gull,* a genus in the order of anseres, the characters of which are—the bill is straight, cultrated, a little crooked at the point, and without teeth. The inferior mandible is gibbous below the apex; the nostrils are linear, a little broader before, and situated in the middle of the beak. The different species are principally distinguished by their colour. The most remarkable are,

1. The *marinus,* or black-backed gull, in length 29 inches, in breadth five feet nine. The bill is very strong and thick, and almost four inches long; the colour a pale yellow; the head, neck, whole under side, tail, and lower part of the back, are white; the upper part of the back and wings are black; the quill feathers tipt with white; the legs of a pale flesh colour. It inhabits several parts of England, and breeds on the highest cliffs. It frequents Greenland, and chiefly inhabits the distant rocks. It lays three eggs in May, placing them on the heaps of dung which the birds leave there from time to time. It is common also in America, as low as South Carolina, where it is called the old-wife.

2. The *cataractes,* or Skua gull, is in length two feet; the extent four feet and a half; the weight three pounds; the feathers on the head, neck, back, scapulars, and coverts of the wings are of a deep brown, marked with rust-colour. This bird inhabits Norway, the Ferroe isles, Shetland, and the noted rock Foula, a little west of them.

3. The *parasiticus,* or dung hunter, is in length 21 inches: the upper parts of the body, wings, and tail, are black; the base of the quills whiter on the inner webs; and the two middle feathers of the tail are near four inches longer than the rest. This is a northern species, and very common in the Hebrides, where it breeds on heath. It is also found in the Orkneys, and on the coasts of Yorkshire, where it is called the feaser.

4. The *canus,* or common gull, is in length 16 or 17 inches; in breadth 36; weight about one pound. The bill is yellow; the head, neck, under parts of the body, and tail, are white; the back and wings pale-grey. It is a tame species, and may be seen by hundreds on the shores of the Thames and other rivers, in the winter and spring, at low tides, picking up the various worms and small fish left by the tides; and will often follow the plough in the fields contiguous, for the sake of worms and insects which are turned up; particularly the cockchafer or dorbeetle in its larva state.

5. The *tridactylus,* or tarrock, is in length 14 inches, breath [illegible]; weight seven ounces. The head, neck, and under parts, are white; near each ear, and under the throat, there is a black spot: at the hind part of the neck a crescent of black; the back and scapulars are blueish-grey; the wing coverts dusky edged with grey, some of the larger wholly grey. This species breeds in Scotland, and inhabits other parts of northern Europe, quite to Iceland and Spitzbergen.

6. The *ridibundus,* peewit, or black-head gull, is in length 15 inches, breadth three feet: weight about ten ounces; the back and wings are of an ash-colour; the neck, all the under parts, and tail, are white. This species breeds on the shores of some of our rivers, but mostly in the inland fens of Lincolnshire, Cambridgeshire and other parts of England. They make their nest on the ground, with rushes, dead grass, &c. and lay three eggs of a greenish brown, marked with red-brown blotches.

LARYNX. See ANATOMY.

LAST, in general, signifies the burden or load of a ship. It signifies also a certain measure of fish, corn, wool, leather, &c. A last of codfish, white herrings, meal and ashes for soap, is 12 barrels; of corn or rapeseed, 10 quarters; of gunpowder, 24 barrels; of red-herrings, 20 cades; of hides, 12 dozen; of leather, 20 dickers; of pitch and tar, 14 barrels; of wool, 12 sacks; of stock fish, 1000; of flax or feathers, 17000 pounds.

LATH, in building, a long, thin, and narrow slip of wood, nailed to the rafters of a roof or ceiling, in order to sustain the covering. These are distinguished into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, sap-laths, and deal-laths; of which the last two are used for ceilings and partitions, and the first for tiling only. Laths are also distinguished according to their lengths; the statute allows but of two lengths, those of five and those of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickness.

LATHE, a very useful engine for the turning of wood, ivory, metals, and other materials. See TURNING.

LATHRÆA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. There are four species.

LATHS, *cleaving of.* The lath-cleavers having cut their timbers into lengths, cleave each piece with wedges into 8, 12, or 16, according to the size of their timber; these pieces are called bolts; this is done by the felt-grain, which is that grain which is seen to run round in rings at the end of a piece of a tree. Thus they are cut out for the breadth of the laths, and this work is called felting. Afterwards they cleave the laths into their proper thickness with their chit, by the quarter grain, which runs in straight lines towards the pith.

LATHYRUS, *chickling vetch,* a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The species are 23.

LATITAT, in law, a writ, which in personal actions, is the commencement of a suit in the King's Bench, where the party is to be arrested in any other county than Middlesex.

LATITUDE, the distance of a place from the equator, or an arc of the meridian intercepted between the zenith of the place and the equator. Hence latitude is either northern or southern, according as the place is north or south of the equator. See GEOGRAPHY.

LATTEN denotes iron plates tinned over, of which tea-canisters are made.

LATTEN-*brass,* plates of milled brass, reduced to different thickness, according to the uses it is intended for.

LATUS *rectum,* in conic sections, the same with parameter.

LATUS *transversum,* in the hyperbola, that part of the transverse diameter, intercepted between the vertices of the two opposite sections.

LAVA, the production of Ætna, Vesuvius

Hecla, and other volcanoes, is of a greyish colour passing to green: it is spotted externally, and occurs porous, carious, or vesicular. Its lustre is vitreous, more or less glistering. It is moderately hard, brittle, easily frangible, and light. It generally attracts strongly the magnetic needle. It is easily fusible into a black compact glass.

LAVANDULA, in botany, *lavender*, a genus of the didynamia gymnospermia class and order: natural order of verticillatæ. Essential character: calyx ovate, obscurely toothed, supported by a bracte; corolla re-supine; stamina within the tube. There are seven species, of which L. spica, common lavender, has a shrubby stem much branched, frequently five or six feet high, with numerous hoary leaves, the upper ones sessile. The flowers are produced in terminating spikes from the young shoots, on long peduncles; the spikes are composed of interrupted whorls, in which the flowers are from six to ten. The usual colour of the corolla is blue, sometimes varying with white flowers. It is a native of the south of Europe, and has long been celebrated for its virtues in nervous disorders; the officinal preparations of lavender, are the essential oil, a simple spirit, and a compound tincture.

LAVATERA, a genus of the polyandria order, in the polydelphia class of plants, and in the natural method ranking under the 37th order columniferæ. There are 9 species, most of them herbaceous flowery annuals, or shrubby perennials, growing erect from two or three to eight or ten feet high.

LAUDANUM. See OPIUM.

LAUNCH, in the sea-language, signifies to put out: as, launch the ship, that is, put her out of the dock; launch aft, or forward, speaking of things that were stowed in the hold, is, put them more forward: launch ho! is a term used when a yard is hoisted high enough, and signifies hoist no more.

LAUREATION, in the universities of Scotland, signifies the act of taking the degree of master of arts, which the students are permitted to do after four years study.

LAURUS, *the bay-tree*, a genus of the monogynia order, in the enneandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is no calyx; the corolla is calycine, or serving in place of the calyx, and sexpartite: the nectarium with three glandules, each terminated by two bristles surrounding the germen. The interior filaments furnished with glandules at the base; the fruit a monospermous plum. There are 32 species, of which the most noted are, *Laurus nobilis*, common sweet bay, grows from twenty to thirty feet in height; it has large evergreen leaves, of a firm texture with an agreeable smell, and an aromatic, bitterish taste; flowers dioecius, or male and female on different trees, in racemes shorter than the leaves, of an herbaceous colour; corollas four-petalled in the male flowers; stamens from eight to twelve; berry superior, of a dark purple colour, almost black; it is a native of the southern parts of Europe and Asia.

Laurus persea, alligator, or avocado pear of the West Indies, is about thirty feet in height; the fruit is the size of one of our biggest pears, inclosing a large seed with two lobes. It is held in great esteem in the West Indies; the pulp is of a pretty firm consistence, and has a delicate rich flavour.

Laurus-cinnamomum, or cinnamon tree, is a native of Ceylon. It has a large root, and divides into several branches, covered with a bark, which on the outer side is of a greyish brown, and on the inside has a reddish cast. The body of the tree, which grows to the height of 20 or 30 feet, is covered, as well as its numerous branches, with a bark, which at first is green and afterwards red. The leaf is longer and narrower than the common bay-tree; and it is three nerved, the nerves vanishing towards the top. The flowers are small and white, and grow in large bunches at the extremity of the branches. The fruit is shaped like an acorn, but is not so large.

LAW. The laws of England are divided into lex non scripta, or the common law; and lex scripta, or statute law. The lex non scripta is not so called from its being conveyed down from former ages by word of mouth, but because the original authority of these laws is not set down in writing, and they receive their force by long usage, and by their universal reception throughout the kingdom.

The common law is divided into two: 1st. General custom, which is the universal rule of the whole kingdom, and is the law by which proceedings and determinations in the courts of justice are ordinarily directed. This for the most part settles the course of inheritance, the manner and form of acquiring and transferring property, the solemnities and obligations of contracts, the rules of expounding wills, deeds, and acts of parliament; the remedies of civil injuries, &c.

2dly. Particular customs which concern the inhabitants of some particular district.

3dly. The third branch are those laws which are adopted by certain courts and jurisdictions as the civil and canon laws.

The civil law is understood to signify the civil law of the Roman empire. The canon law is a body of Roman ecclesiastical law relating to matters over which the church exercises a jurisdiction. The civil law is used in four courts, under certain restrictions, viz. the archbishops' and bishops' courts, usually styled curiæ christianitatis; the courts martial, the courts of admiralty, and the courts of the two universities.

The second division of the laws of England are the statutes made by the king, lords, and commons, assembled in parliament. The oldest statute extant is the celebrated Magna Charta.

Statutes are general or special, public or private: general or public acts are those which concern the whole nation; of these the judges are obliged to take notice, though they should not be formally pleaded by the party who claims an advantage under them. Special or private acts are such as operate on private persons and concerns, which must be formally set forth by the party, or the judges are not obliged to notice them.

Statutes are either declaratory of the common law, where it is become disreputable, or fallen into disuse; or remediable, when made to supply the defects, or abridge the superfluities of the common law.

There is besides those grounds of the laws of England, a court of equity to moderate and explain them. The courts of equity are, howeve

only had recourse to in matters of property; for our constitution will not permit, that in criminal cases any judge should have the power of construing the law otherwise than according to the letter.

In treating of the laws, the best mode is to divide them, 1st, Into the rights of persons, or the rights as to personal security, personal liberty, and private property. 2nd, The rights of things, or the rights which a man may acquire in, and to such external things as are unconnected with his person. 3d, Private wrongs, or such as are the infringement of the private rights of individuals; and 4th, Public wrongs, or such as are a violation of the public rights, and affect the whole community.

LAW *of nations*, is a system of rules deducible by natural reason, from the immutable principles of natural justice, and established by universal consent among the civilized inhabitants of the world, in order to decide all disputes, and to insure the observance of justice and good faith, in that intercourse which must frequently occur between them and the individuals belonging to each; or they may depend upon mutual compacts, treaties, leagues, and agreements between the separate, free, and independent communities. In the construction of these principles, there is no judge to resort to, but the general law of nature and of reason, being the only law with which the contracting parties are all equally conversant, and to which they are all equally amenable.

LAWSONIA, *Egyptian privet*, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is quadrifid; the petals four; the stamina four, in pairs; the capsule is quadrilocular and polyspermous. There are four species, all natives of India.

LAXMANNIA, in botany, a genus of the hexandria monogynia class and order. Essential character: calyx one-leafed, four-toothed, inferior; corolla four petalled; berry four-celled; seeds solitary.

LAY-BROTHERS, among the Romanists, those pious but illiterate persons, who devote themselves, in some convent to the service of the religious.

LAY-MAN, among painters, a small statue whose joints are so formed, that it may be put into any attitude for the purpose of adjusting the drapery of figures.

LAYERS, are tender shoots, or twigs of trees, laid in the ground; till having struck root they are separated from the parent tree, and become distinct plants.

LAZULITE. This mineral is often found in oblique quadrangular crystals of a fine blue colour. It is translucent only on the edges, brittle, and nearly as hard as quartz. When massive, it is either in grains, or in pieces of the size of a hazel nut. It occurs imbedded in mica slate. Its lustre is vitreous. Its constituents are 66 alumina, 18 magnesia, 10 silica, 2.5 oxide of iron, 2 lime. It occurs in Vorau in Stiria, in a gangue of quartz: but the finest specimens of it come from the bishopric of Salzburg.

LEAD is a white metal of a considerably blue tinge, very soft and flexible, not very tenacious, and consequently incapable of being drawn into fire, though it is easily extended into thin plates under the hammer. Its sp. gr. is 11.35. It melts at 612°. In a strong heat it boils, and emits fumes; during which time, if exposed to the air, its oxidation proceeds with considerable rapidity. Lead is brittle at the time of congelation. In this state it may be broken to pieces with a hammer, and the crystallization of its internal parts will exhibit an arrangement in parallel lines. Lead is not much altered by exposure to air or water, though the brightness of its surface, when cut or scraped, very soon goes off. It is probable that a thin stratum of oxide is formed on the surface, which defends the rest of the metal from corrosion.

There are certainly two, perhaps three oxides of lead:—1. The powder precipitated by potash from the solution of the nitrate of lead, being dried, forms the yellow protoxide. When somewhat vitrified, it constitutes litharge, and combined with carbonic acid, white-lead or ceruse.

2. When massicot has been exposed for about 48 hours to the flame of a reverberatory furnace, it becomes red-lead, or minium. This substance has a sp. gr. of 8.94. At a red heat it gives out oxygen, and passes into vitrified protoxide. It consists of 100 lead + 11.08 oxygen; and it may be represented as a compound of 2 primes of lead + 3 oxygen; or of 1 prime protoxide + 1 prime peroxide.

3. If upon 100 parts of red-lead we digest nitric acid of the sp. gr. 1.26, 92.5 parts will be dissolved, but 7.5 of a dark brown powder will remain insoluble. This is the peroxide of lead.

By passing a stream of chlorine through red-lead diffused in water, we obtain a solution, which yields by potash an abundant precipitate of the brown oxide of lead.

Most of the acids attack lead. The sulphuric does not act upon it, unless it be concentrated and boiling. Sulphurous acid gas escapes during this process, and the acid is decomposed. When the distillation is carried on to dryness, a saline white mass remains, a small portion of which is soluble in water, and is the sulphate of lead; it affords crystals. Nitric acid acts strongly on lead.

Muriatic acid acts directly on lead by heat, oxidizing it, and dissolving part of its oxide.

The acetic acid dissolves lead and its oxides; though probably the access of air may be necessary to the solution of the metal itself in this acid. *White-lead* or *ceruse*, is made by rolling leaden plates spirally up, so as to leave the space of about an inch between each coil and placing them vertically in earthern pots, at the bottom of which is some good vinegar. The pots are to be covered, and exposed for a length of time to a gentle heat in a sand bath, or by bedding them in dung. Ceruse is the only white used in oil paintings. Commonly it is adulterated with a mixture of chalk in the shops. This, like all the preparations of lead, is a deadly poison. The common sugar of lead is an acetate; and Goulard's extract, made by boiling litharge in vinegar, a subacetate. The power of this salt, as a coagulator of mucus, is superior to the other. If a bit of zinc be suspended by brass or iron wire, or a thread, in a mixture of water and the acetate of lead, the lead will be revived, and form an arbor Saturni.

The acetate, or sugar of lead, is usually crystallized in needles, which have a silky appearance. They are flat four-sided prisms with dihedral summits, Its sp. gr. is 2.345. It is soluble in three and a half times its weight of cold water, and in somewhat less of boiling water.

When lead is alloyed with an equal weight of tin, or perhaps even less, it ceases to be acted on by vinegar. Actetate and subacetate of lead in solution, have been used as external applications to inflamed surfaces, and scrofulous sores, and as eye-washes. The colic of the painters, and that formerly prevalent in certain counties of England, from the lead used in the cyder presses, shew the very deleterious operation of the oxide, or salts of this metal, when habitually introduced into the system in the minutest quantities at a time.

Dealers in wines have occasionally sweetened them, when acescent, with litharge or its salts. This deleterious adulteration may be detected by sulphuretted hydrogen water, which will throw down the lead in a state of a dark brown sulphuret. Or, subcarbonate of ammonia, which is a very delicate test, may be employed to precipitate the lead in the state of a white carbonate; which, on being washed and digested with sulphuretted hydrogen water, will instantly become black. Chromate of potash will throw down from saturnine solutions a beautiful orange-yellow powder. Burgundy wine, and all such as contain tartar, will not hold lead in solution, in consequence of the insolubility of the tartrate.

Lead unites with most of the metals. Gold and silver are dissolved by it in a slight red heat. Both these metals are said to be rendered brittle by a small admixture of lead, though lead itself is rendered more ductile by a small quantity of them.

Iron does not unite with lead, as long as both substances retain their metallic form. Tin unites very easily with this metal, and forms a compound, which is much more fusible than lead by itself, and is, for this reason, used as a solder for lead. Two parts of lead and one of tin, form an alloy more fusible than either metal alone: this is the solder of the plumbers. Bismuth combines readily with lead, and affords a metal of a fine close grain, but very brittle. A mixture of eight parts bismuth, five lead, and three tin, will melt in a heat below that of boiling water. Antimony forms a brittle alloy with lead. Nickel, cobalt, manganese, and zinc, do not unite with lead by fusion. All the oxides of lead are easily revived with heat and carbon.

LEAF. See Botany.

Leaf-*gold.* See Gold, Gilding, &c.

Leaf. See Architecture.

LEAGUE, a measure of length, containing more or less geometrical paces, according to the different usages and customs of countries. A league at sea, where it is chiefly used by us, contains three thousand geometrical paces, or three English miles. The French league sometimes contains the same measure, and in some parts of France it consists of three thousand five hundred paces: the mean or common league consists of two thousand four hundred paces, and the little league of two thousand. Seventeen Spanish leagues make a degree, or sixty-nine and a half English statute miles. The Dutch and German leagues contain each four geographical miles. The Persian leagues are nearly of the same extent with the Spanish; that is, they are equal to four Italian miles, which is pretty near to what Herodotus calls the length of the Persian parasang, which contained thirty stadia, eight of which make a mile.

LEAK, among seamen, is a hole in the ship through which the water comes in. To spring a leak is said of a ship that begins to leak; to stop a leak, is to fill it with a plug wrapt in oakum and well tarred; or putting in a tarpaulin clout, to keep the water out; or nailing a piece of sheet lead upon the place.

LEAKAGE, the state of a vessel that leaks, or lets water, or other liquid, ooze in or out. Leakage, in commerce, is an allowance of 12 per cent. in the customs, allowed to importers of wines, for the waste and damage it is supposed to have received in the passage; an allowance of two barrels in twenty-two is also made to the brewers of ale and beer, by the excise office.

LEAP, in music. This word is properly applicable to any disjunct degree, but is generally used to signify a distance consisting of several intermediate intervals.

Leap-*year.* See Bissextile.

LEASE, a conveyance of lands, generally in consideration of rent or other annual recompence made for life, for years, or at will, but always for a shorter term than the lessor has in the premises, otherwise it partakes more of the nature of an assignment.

All leases of lands, except leases not exceeding three years, must be made in writing, and signed by the parties themselves, or their agents duly authorised, otherwise they will operate only as leases at will. If a lease is but for half a year, or a quarter, or less time, the lessee is respected as a tenant for years. To constitute a good lease, there must be a lessor not restrained from making the lease to the extent for which it is granted; a lessee capable of receiving it; and the interest demised must be a demisable interest, and be sufficiently and properly described. If it is for years, it must have a certain commencement and determination; it is to have all the usual ceremonies as sealing, delivery, &c.; and there must be an acceptance of the thing demised.

The following points may be necessary to be specified here concerning leases. First, they must have a certain commencement and end. Leases for life must not be made to commence at a future day, and there must be a livery of seisin. They must now be stamped as a lease, to be valid; and any form of writing will constitute a lease, provided it contains words of present demise, or actual letting; but if it be only an agreement to let, it conveys no immediate title in law, but only an equitable right to have a lease, or to sue at law for not making one. If a lease is made to one for years, and at the same time to another for a longer time, the last lease is not void, but shall take effect after the first expires. A tenant for life can, in general, only grant a lease to endure during his life, but sometimes a power is annexed to such an estate, to grant leases for a specified time, and under particular limitations, all which must be strictly complied with, or the lease is void; and instances have happened, where building-leases have been set aside, and persons ruined by having granted under-leases. An infant may make a lease; but may set it aside when he comes of age; and the Court of Chan-

cery is empowered to grant leases for idiots, lunatics, infants, and married women.

The rent must be reserved to the executor or the heir of the lessor, according as his estate is real or personal. Lessees are bound to repair, unless the contrary is specified; and although if the house is burnt by accident they are not bound to rebuild, yet they must if the fire be by negligence; and if there is a covenant to pay rent, and a covenant to repair, except in case of fire, yet rent is payable, although the house is not rebuilt by the landlord. If there is a covenant not to assign, lease, or under-let, without licence of the landlord, the tenant cannot even grant an under-lease.

Upon a lease at will, six months' notice to quit must generally be given by either party, to determine on the same day in the year when the lease commenced. Leases made by spiritual persons of their church-lands, must be strictly conformable to certain statutes called the enabling and disabling statutes. The tenant may, at the trial of an ejectment, insist upon his notice to quit being insufficient, although he made no objection when it was served.

LEASES, *value of.* The purchaser of a lease may be considered as the purchaser of an annuity equal to the rack-rent of the estate; and the same principles from which are deduced the present value of annuities to continue during any given term, will apply to the value of leases. The sum paid down for the grant of a lease is so much money paid in advance for the annual rents as they may become due; or, it may be considered as a sum which put out to interest, will enable the lessor to repay himself the rack-rent of the estate, or the yearly value of his interest therein, during the given term. In order to find what this sum should be, it would be necessary to ascertain separately the present value of each annual rent, or the sum which, put out to interest at the given rate, will enable the landlord to repay himself the several yearly rents as they become due. The following Table shews the number of years' purchase that ought to be given for a lease, for any number of years not exceeding 100, at 6, 7, and 8 per cent. interest.

	6 per Cent.	7 per Cent.	8 per Cent.

In order to find the value of a lease, it is first necessary to ascertain the true rack-rent of the estate, or the annual value that it may be justly estimated to be worth. On this point difficulties will sometimes arise; for the value of an estate depending very often on some real or supposed advantages, or on some local or personal recommendations, will in many instances, occasion a difference of opinion. However, when all these circumstances have been taken into consideration, some annual rent equivalent thereto must be assumed, and when this is settled the value of the lease will be easily found. Thus, if an estate is worth 150*l.* yearly rent, the value of a lease thereof for sixty-nine years, allowing the purchaser 6 per cent. interest for his money, is 16,3676 (the number in the table) multiplied by 150, or 2455*l.* 2*s.* 9*d.* In many instances, the rent of the estate intended to be leased is charged with some annual expence, such as a reserved or quit rent, the payment of an annuity, taxes, and the like; in such cases the number of years' purchase found in the table ought to be multiplied by the difference only between such annual expence and the whole estimated rent of the estate.

In order to find the annual rent corresponding to any given sum paid for a lease, divide the sum paid by the number of years' purchase that are found against the given term in the table, and the quotient will be the annual rent required. Example:—A person has given 1000*l.* for the lease of an estate for 16 years, what annual rent is equivalent thereto, in order to allow the purchaser 7 per cent. interest for his money. In the table against 16 years, and under 7 per cent. we shall find the number of years' purchase to be 9,4466; therefore 1000 divided by 9,4466 gives 105*l.* 17*s.* for the annual rent required.

It frequently happens that a long lease is not to be entered on or enjoyed till after the expiration of a short lease, or till the end of a given number of years; in such cases, deduct the value of the short lease, or the value set against the given number of years in the table, from the value of the longer lease, and the difference will give the true present value of the longer lease.

LEASE and RELEASE, a conveyance of the fee simple, right, or interest, in lands or tenements, under the statute of uses, 27 Henry VIII. c. 10, giving first the possession, and afterwards the interest, which in law is equivalent to a feoffment. It was invented to supply the place of livery of seisin, and is thus contrived: a lease, or rather bargain and sale, upon some pecuniary consideration, for one year, is made by the tenant of the freehold to the lessee or purchaser, which vests in him the use of the term for a year; and then the statute of uses, 27 Henry VIII. c. 10, immediately transfers the use into possession.

LEATHER. See TANNING.

LEAVEN. See FERMENTATION.

LECHŒA, a genus of the triandria trigynia class and order. There are three species, herbaceous plants of America and China.

LEDGER, the principal book wherein merchants enter their accounts. See BOOK-KEEPING.

LEDGES in a ship, are small pieces of timber lying athwart from the waste-trees to the roof-trees: they serve to bear up the gratings or nettings over the half-deck.

LEDUM, marsh cistus, or wild rosemary; a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 18th order, bicornes.

There are three species:—the palustre with very narrow leaves, grows naturally upon bogs and mosses in many parts of Yorkshire, Cheshire, and Lancashire.

LEE, in the sea language, a word of various significations, though it is generally understood to mean the part opposite to the wind. Thus lee-shore, is that shore against which the wind blows. Lee-latch, or have a care of the lee-latch, is, take care that the ship do not go to the leeward, or too near the shore; a lee the helm, put it to the leeward side of the ship; to lie by the lee, or to come up to the lee, is to bring the ship so, that all her sails may lie flat against her masts and shrouds, and that the wind may come right upon her broadside.

LEE-WAY, is the angle that the rhumb-line upon which the ship endeavours to sail, makes with the rhumb upon which she really sails.

LEEA, a genus of the class and order pentandria monogynia. The calyx is one-petalled; nect. on the side of the corolla, upright, five-cleft; berry, five-seeded, There are three species, trees of the East Indies.

LEECH. See HIRUDO.

LEEK. See ALLIUM.

LEERSIA, a genus of the class and order triandria digynia. Calyx none; glume, two-valved, closed. There are three species, grasses of America.

LEET, a little court held within a manor, and called the king's court; because its authority to punish offences originally belonged to the crown.

LEETCH-*lines*, small ropes made fast to the leetch of the top-sails, to which they belong, and reeved into a block at the yard close by the top-sail-ties.

LEGACY, a bequest of a sum of money, or any personal effects of a testator; and these are to be paid by his representatives, after all the debts of the deceased are discharged, as far as the assets will extend.

All the goods and chattels of the deceased are by law invested in the representative, who is bound to see whether there be left a sufficient fund to pay the debts of the testator, and if it should prove inadequate, the pecuniary legacies must proportionally abate; a specific legacy, however, is not to abate unless there be insufficient without it. If the legatee die before the testator, such will in general be termed a lapsed legacy, and fall into the general fund; where, however, from the general import of the will, it can be collected that the testator intended such a vested legacy, it will in such case go to the representative of the deceased legatee. If a bequest be made to a person, if or when he attains a certain age, the legacy will be lapsed, if he die before he attain that age. But if such legacy may be made payable at that age, and the legatee die before that age, such legacy will be vested in his representative. If in the latter case, the testator devise interest to be paid in the mean time, it will nevertheless be a vested legacy.

Where a legacy is bequeathed over to an-

other, in case the first legatee die under a certain age, or the like, the legacy will be payable immediately on the death of the first legatee; and though such legacy be not bequeathed over, yet if it carry interest, the representative will become immediately entitled to it.

In case of a vested legacy due immediately, and charged on land, or money in the funds which yields an immediate profit, interest shall be payable from the death of the testator; but if it be charged on the personal estate only of the testator, which cannot be collected in, it will carry interest only from the end of the year after the death of the testator.

If a bequest be for necessaries, and of small amount, the executor will be justified in advancing a part of the principal; but this should be done under very particular circumspection, as the executor may be compelled to pay the full legacy on the infant's attaining his majority, without deducting the sum previously advanced.

When all the debts and particular legacies are discharged, the residue or surplus must be paid to the residuary legatee, if any be so appointed in the will; but if there be none appointed or intended, it will go to the executor or next of kin. When this residue does not go to the executor, it is to be distributed among the intestates next of kin, according to the statute of distributions; except the same is otherwise disposable by particular customs, as those of London, York, &c. See Executor.

LEGATE, a cardinal or bishop, whom the Pope sends as his ambassador to sovereign princes.

LEGERDEMAIN, a term applied to certain deceptive performances, which depend either on dexterity and address, or derive but a small degree of aid from philosophical principles.

The grand requisite in the exercise of this art is, to take off the attention, as much as possible, from the fingers of the performer; and this is generally effected by the volubility of tongue which he displays during the performance of his tricks. Immense labour is necessary to acquire superiority in this art. One of the most eminent performers that ever appeared in this country assured the editor, that for twenty years he had practised in private in the most laborious manner, and that he found it necessary to continue this regularly. In contemplating this subject, it is impossible to avoid being struck with the similarity between it and the amazing execution of the skilful musician. Both the juggler and the musician can carry on, with undeviating correctness, the operations of their fingers, while they are engaged in talking on subjects of a very opposite nature.

Dugald Stewart, in his elements of the philosophy of the human mind, has a remark which, as it certainly accounts on just grounds for the dexterity acquired by the professors of legerdemain, we shall here give in his own words.

"The dexterity of jugglers (which, by the way, merits a greater degree of attention from philosophers than it has yet attracted) affords many curious illustrations of the same doctrine —alluding to the possibility of our exerting acts of the *will*, which we are unable to recollect. "The whole of this art seems to me to be founded on this principle: that it is possible for a person, by long practice, to acquire a power, not only of carrying on certain intellectual processes more quickly than other men, (for all the feats of legerdemain suppose the exercise of observation, thought, and volition,) but of performing a variety of movements with the hand, before the eyes of a company, in an interval of time too short to enable the spectators to exert that degree of attention which is necessary to lay a foundation for memory."

LEGION, in Roman antiquity, a body of foot which consisted of different numbers at different periods of time. The word comes from *legere*, to choose, because when the legions were raised the Romans made choice of such of their youth as were most proper to bear arms. Romulus fixed the number of the legion at 3000; but, according to Plutarch, he afterwards increased it to 6000.

LEGUMEN, in botany, that species of seed vessel termed a pod, in which the seeds are fastened along one suture only. In this the seed-vessel in question differs from the other kind of pod, termed by botanists siliqua, in which the enclosed seeds are fastened alternately to both the sutures or joinings of the valves. The seed-vessels of all the pea-bloom or butterfly-shaped flowers, the Diadelphia of Linnæus, is of the leguminous kind; such is the seed-vessel of the pea, vetch, lupine, &c.

LEMMA, in mathematics, a proposition which serves previously to prepare the way for the more easy apprehension of the demonstration of some theorem, or construction of some problem.

LEMNA, a genus of the monœcia diandria class and order. The male cal. is one-leaved; cor. none; female, cal. one-leaved; cor. none; style one; caps. one-celled. There are six species, known by the name of duck-weed, or duck-meat.

LEMNISEA, a genus of the class and order polyandria monogynia. The cal. is five-toothed; cor. six-petalled, recurved; nect. cap-shaped, girding; the germ. per. five-celled, seeds solitary. There is one species, a tree of Guiana.

LEMON. See Citrus.

Lemon, *salt of*. See Oxalate of potass.

LEMUR, *macauco*, a genus of quadrupeds of the order primates: the generic character is, front-teeth in the upper jaw, four; the intermediate ones remote: in the lawer jaw, six; longer, stretched forwards, compressed, parallel, approximated; canine teeth solitary, approximated; grinders several, sublobated; the foremost somewhat longer and sharper.

The genus lemur consists of animals approaching to monkeys in the form of their feet, which, in most species, are furnished with flat nails; but differing in their manners, and void of that mischievous and petulent disposition which so much distinguishes the monkey tribe from other quadrupeds.

There are thirteen species, of which the following are the most remarkable —

L. *tardigradus*, or the loris. This is of a light brown colour, and of the usual size of a cat. It walks and climbs with great slowness and is supposed incapable of leaping. Its manners are gentle and interesting, it is extremely susceptible of cold, and when exposed to a

strong degree of it, is agitated with extreme uneasiness. It sleeps from sun-rise to sun-set without intermission, rolled up in the manner of the hedge-hog: it is extremly attentive to cleanliness, licking its full and rich fur with the same assiduity as a cat. Its food consists of plantains, mangoes, and other fruits, and it is remarkably fond of grasshoppers.

L. indri, is a native of Madagascar, is the largest of the genus, has a face of a dog-like form, and a fur thick and soft. It has no appearance of a tail: it is very docile, and sometimes trained by the natives to hunt various animals. It is about three feet and a half in height.

L. macauco, or the ruffed macauco, is found in some of the Indian islands, and is particularly numerous at Madagascar. It is full of energy and fierceness, and its voice is so strong as to fill the woods with its sound.

L. catta, or the ring-tailed macauco. In their state of nature these animals are seen in companies of twenty or thirty. They feed on almost every species of fruits, and, in a state of confinement, like several others of this genus, will take animal food without any hesitation. They are the most elegant and beautiful species of the whole genus, are lively and gentle, and so agile and elegant in their movements, as to be highly interesting. This animal inhabits Madagascar, is of the size of a small cat, which it resembles in purring.

LENS, in dioptrics, properly signifies a small roundish glass, of the figure of a lentil; but is extended to any optic glass, not very thick, which either collects the rays of light into a point, in their passage through it, or disperses them further apart, according to the laws of refraction. See OPTICS.

LEO, in astronomy, one of the twelve signs of the zodiac, the fifth in order; containing, according to Ptolemy, thirt-ytwo stars; according to Tycho, thirty-seven; and in the Britannic catalogue, there are no less than ninety-four. The star called the lion's heart, cor-leonis, regulus, and basilicus, is a fixed star of the first magnitude.

LEONTICE, *lion's leaf*, is a genus of the monogynia order, in the hexandria class of plants: and in the natural method ranking under the 24th order, corydales. There are three species, natives of the southern parts of Europe, two of which are sometimes cultivated in this country. These are, 1. The chrysogonum with winged leaves: and 2. The leontopetalum with decompounded leaves. But those plants are natives of the Archipelago islands, and also grow in the corn-fields about Aleppo in Syria, where they flower soon after Christmas.

LEONTODON, *dandelion*, a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the calyx imbricated, with the scales somewhat loose; the pappus feathery. There are four species, of which the only remarkable one is the taraxacum, or common dandelion, found on the road sides, in pastures, and on the banks of ditches.

LEOPARD. See FELIS.

LEOPARD'S *bane*. See DORONICUM.

LEPAS, a genus of vermes testacea: the animal a triton, shell affixed at the base, and consisting of many unequal erect valves. The lepas antifera, or duck-barnacle, has the shell compressed, five-valved, smooth, seated on a peduncle. It inhabits most seas, and is found fixed in clusters to the bottom of vessels, and old pieces of floating timber, generally whitish with a blue cast, the margin of the valves yellow; sometimes marked with black; peduncle long, coriaceous, black, and much wrinkled towards the shell, and growing pale and pellucid towards the base.

LEPIDIUM, DITTANDER, or *pepper-wort*: a genus of the siliculosæ order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosæ. There are 23 species, of which the only remarkable one is the latifolium or common ditander. This is a native of many parts of England.

LEPIDOPTERA, in zoology, an order of insects with four wings, which are covered with imbricated squamulæ: add to this that the mouth is commonly spiral.

Under this order are comprehended the phalæna, sphinx, and papilo genera.

LEPISMA, a genus of insects of the order aptera; lip membranceous, rounded, emarginate; four feelers, of which two are setaceous, and two capitate; antennæ setaceous; body imbricate, with scales; tail ending in setaceous bristles; six legs, formed for running. There are seven species; of these the principal is L. saccharina; scaly, silvery, lead-colour, with a triple tail. It inhabits America, among sugar, but is naturalized in Europe, and found among old books and furniture; it runs exceedingly swift, and is caught with difficulty.

LEPROSY, a foul cutaneous disease, appearing in dry, white, thin, scurfy scabs, either on the whole body, or only some part of it, and usually attended with a violent itching, and other pains. Leprosy is of various kinds; but that to which the Jews were so subject, was the elephantiasis.

LEPUS, *hare*, a genus of quadrupeds of the order glires. The generic character is, front-teeth two both above and below, the upper pair duplicate; two small interior ones standing behind the exterior. This genus exhibits particularities of structure, deviating somewhat from that of the glires, and making an indistinct approach to the pecora or ruminants.

The most remarkable species are:—1. *Lepus timidus*, common hare. The hare is an animal so familiarly known as to supersede the necessity of minute description. It is a native not only of every part of Europe, but of almost every part of the old continent. It may perhaps be doubted whether it is an aboriginal native of any part of America.

The favourite residence of the hare is in rich, dry, and flat grounds: it is rarely discovered in very hilly or mountainous situations. It feeds principally by night, and remains concealed during the day in its form, beneath some bush, or slight shelter. The swiftness of this animal is proverbial, and on account of the conformation of its fore-legs, it is observed to run to most advantage on slightly ascending ground. The hare is a very prolific animal, generally producing three or four young at a time, and breeding several times in a year The hare is an animal proverbially timid, and flies, if disturbed, by the slightest alarm. A most sin-

gular variety of this animal is sometimes found, which is furnished with rough and slightly branched horns, bearing a considerable resemblance to those of a roe-buck.

2. *Lepus variabilis,* varying hare. This species is an inhabitant of the loftiest alpine tracts in the northern regions of the globe; occurring in Norway, Lapland, Russia, Siberia, and Kamtschatka; and in our own island on the mountains of Scotland. In its general appearance it bears an extreme resemblance to the common hare, but is of smaller size, and has shorter ears and more slender legs. Its colour in summer is a tawny grey; in winter entirely white, except the tips of the ears, which are black. This animal is observed to confine itself altogether to elevated situations, and never to descend into the plains, or to mix with the common hare. The change of colour commences in the month of September, and the grey or summer coat re-appears in April; but in the very severe climate of Siberia, it continues white all the year round.

3. *Lepus Americanus,* American hare. This animal is not much superior in size to a rabbit, measuring about eight inches. Its colour nearly resembles that of the common hare, to which it seems much allied; but the fore legs are shorter, and the hind ones longer in proportion. The belly is white; the tail black above and white beneath. The ears tipped with grey, and the legs of a pale-ferruginous colour.

4. *Lepus cuniculus,* rabbit. The rabbit bears a very strong general resemblance to the hare, but is considerably smaller, and its fore feet are furnished with sharper and longer claws in proportion. Thus enabling it to burrow in the ground, and to form convenient retreats. Its colour, in the wild state, is a dusky brown, paler or whitish on the under parts, and the tail is black above and white below. In a domestic state the animal varies into black, black and white, silver grey, perfectly white, &c. The rabbit is a native of most of the temperate and warmer parts of the old continent, but is not found in the northern regions, and is not originally a native of Britain, but was introduced from other countries. Its general residence is in dry, chalky, or gravelly soils, in which it can conveniently burrow. It is so prolific an animal that it has been known to breed seven times in a year, and to produce not less than eight young each time.

Besides the above there are the Lepus Viscaccia; the Alpinus; the Octogono; and the Pusillus.

LESKIA, a genus of the class and order cryptogamia musci; a moss of little note.

LESSOR and **LESSEE,** in law. See LEASE.

LETHARGY, in medicine, a disease wherein such a profound drowsiness or sleepiness attends the patient, that he can scarce be awaked, and if awaked, he remains stupid, without sense or memory, and presently sinks again into his former sleep.

LETTER, a character used to express one of the simple sounds of the voice; and as the different simple sounds are expressed by different letters, these, by being differently compounded, become the visible signs or characters of all the modulations and mixtures of sounds used to express our ideas in a regular language.

Letters are distinguished into vowels, consonants, mutes, liquids, diphthongs, and characteristics. They are also divided into labial, dental, guttural, and palatal, and into capital and small letters. They are also denominated from the shape and turn of the letters: and in writing are distinguished into different hands, as round-text, german-text, round-hand, Italian, &c. and in printing into roman, italic, and black letter. See ALPHABET WRITING, and FOUNT.

LETTER. A servant of the post-office is within the penalty of 5 Geo. III. c. 25, which makes it a capital felony to secrete a letter containing any bank note, though he has not taken the oath required by 9 Anne, c. 10.

LETTER *of credit,* is where a merchant or correspondent writes a letter to another, requesting him to credit the bearer with a certain sum of money.

LETTER *of licence,* is a written permission granted to a person under embarrassment, allowing him to conduct his affairs for a certain time without being molested.

LETTER *of attorney,* is an instrument giving to a second person the authority to do any lawful act in the stead of the maker. They are sometimes revokable and sometimes not: in the latter case the word irrevocable is inserted. The authority must be strictly pursued; and if the attorney does less than the power it shall be void; if more, it shall be good as far as the power goes, and void as to the rest.

LETTERS, *threatening.* To send letters threatening to accuse a person of any crime punishable with death or any infamous punishment, and knowingly to send any anonymous or fictitious letter threatening to kill any one, or set fire to their tenements or property, with a view of extorting money or valuables from them, is in the first instant punishable with fine, imprisonment, pillory, whipping, or transportation for seven years, and in the other instance is felony without benefit of clergy.

LETTERS *patent.* See PATENTS.

LETTERS, *close,* are grants of the king specially distinguished from letters patent, in that the letters close, being not of public concern, but directed to particular persons, are closed up and sealed.

LETTERS *of marque,* are extraordinary commissions, granted to captains or merchants for reprisals, in order to make a reparation for those damages they have sustained, or the goods they have been deprived of by strangers at sea

These appear always joined to those of reprise, for the reparation of a private injury: but under a declared war the former only are required.

LEVARI *facias,* is a writ directed to the sheriff for levying a certain some of money upon the lands, &c. of a person who has forfeited his recognizance.

LEUCITE. This stone is usually found in volcanic productions. It is always crystallized. The primitive form of its crystals is either a cube or a rhomboidal dodecanhedron, and its integrant molecules are tetrahedons; but the varieties hitherto observed are all polyhedrons. Its texture is foliated; its fracture somewhat conchoidal: specific gravity from 2.455 to 2.490: colour white, or greyish white. It is

composed of 54 parts silica, 23 alumina, 32 potass.

LEVEL, an instrument used to make a line parallel to the horizon, and to continue it out at pleasure; and by this means to find the true level, or the difference of ascent or descent, between two or more places, for conveying water, draining fens, &c. See NAVIGATION, INLAND, and SURVEYING.

LEVELLING. See as above.

LEVER. See MECHANICS.

LEVIGATION. The mechanical process of grinding the parts of bodies to a fine paste, by rubbing the flat face of a stone called the muller, upon a table or slab called a stone. Some fluid is always added in this process. The advantage of levigation with a stone and muller, beyond that of triturating in a mortar, is, that the materials can more easily be scraped together, and subjected to the action of the muller, than in the other case to that of the pestle; and, from the flatness of the two surfaces, they cannot elude the pressure.

LEY, or *lees*, a term usually applied to any alkaline solution made by levigating any ashes that contain an alkali. Soap lees is an alkali used by soap-boilers, or potash or soda in solution, and made caustic by lime. Lees of wine are the refuse, or sediment, that deposits from wine by standing quiet.

LEYDEN *phial.* See ELECTRICITY.

LEYSERA, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ.

LIBEL, injurious reproaches or accusations written and published against the memory of one who is dead, or the reputation of one who is alive, and thereby exposing him to public hatred, contempt, and ridicule.

With regard to libels in general, there are, as in many other cases, two remedies; one by indictment or information, and the other by action. The former for a public offence; for every libel has a tendency to the breach of the peace, by provoking the person libelled to break it; which offence is said to be the same in point of law, whether the matter contained is true or false; and therefore it is that the defendant on an indictment for publishing a libel, is not allowed to allege the truth of it by way of justification. But in the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, justify the truth of the facts, and shew that the plaintiff has received no injury at all. The chief excellence therefore of a civil action for a libel consists in this, that it not only affords a reparation for the injury sustained, but it is a full vindication of the innocence of the person traduced.

LIBEL, in the ecclesiastical court, is the declaration or charge drawn up in writing, on the part of the plaintiff, to which the defendant is obliged to answer.

LIBEL, in the law of Scotland, signifies an indictment.

LIBELLULA, *dragon-fly*, a genus of insects of the order neuroptera. The generic character is:—mouth furnished with several jaws; antennæ very short; wings four, extended; tail (in the male) hook-forcipated.

The *libellulæ*, or dragon flies, sometimes called by the very improper title of horse-stingers, exhibit an instance scarcely less striking than the butterfly of that strange dis-similitude in point of form under which one and the same animal is destined to appear in the different periods of its existence. Perhaps few persons not particularly conversant in the history of insects, would imagine that these highly brilliant and lively animals, which may be seen flying with such strength and rapidity round the meadows, and pursuing the smaller insects with the velocity of a hawk, had once been inhabitants of the water, and that they had resided for a very long space of time in that element before they assumed their flying form. Of the libellulæ there are about sixty different species, both native and exotic.

LIBERTY, in its most general signification, is said to be a power to do as one thinks fit; unless restrained by the law of the land: and it is well observed, that human nature is ever an advocate for this liberty; it being the gift of God to man in his creation. It is upon that account the laws of England in all cases favour liberty. According to Montesquieu, liberty consists principally in not being compelled to do any thing which the law does not require; because we are governed by civil laws, and therefore we are free, living under those laws.

The absolute rights of man, considered as a free agent, endowed with discernment to know good from evil, and with power of choosing those measures which appear to him to be most desirable, are usually summed up in one general appellation, and denominated the natural liberty of mankind. This natural liberty consists properly in a power of acting as one thinks fit, without any restraint or controul, unless by the law of nature; being a right inherent in us by birth, and one of the gifts of God to man at his creation, when he endowed him with the faculty of free will.

But every man, when he enters into society, gives up a part of his natural liberty, as the price of so valuable a purchase; and in consideration of receiving the advantages of mutual commerce, obliges himself to conform to those laws which the community has thought proper to establish. This species of legal obedience is infinitely more desirable than that wild and savage liberty, which is sacrificed to obtain it. For no man, who considers a moment, would wish to retain the absolute and uncontrouled power of doing whatever he pleases; the consequence of which is, that every other man would also have the same power; and then there would be no security to individuals in any of the enjoyments of life.

Political or civil liberty, therefore, which is that of a member of society, is no other than natural liberty, so far restrained by human laws, and no further, as is necessary and expedient for the general advantage of the public.

Political liberty is distinguished by Mr. Christian from civil liberty, and he defines it to be the security with which, from the constitution, form, and nature of the established government, the subjects enjoy civil liberty. No ideas, continues he, are more distinct than those of civil and political liberty. Yet they are generally confounded; and the latter can

not yet claim an appropriate name. The learned judge (Blackstone) uses political and civil liberty indiscriminately; but it would perhaps be convenient uniformly to use those terms in the respective senses here suggested, or to have some fixed specific denominations for ideas which, in their natures, are so widely different. The last species of liberty has most engaged the attention of mankind, and particularly of the people of England. The people of England have a firm reliance that this civil liberty is secured to them under the constitution of the government.

LIBERTUS, in Roman antiquity, a person who from being a slave, had obtained his freedom. The difference between the liberti and libertini was this: the liberti were such as had been actually made free themselves, and the libertini were the children of such persons.

LIBRA, *the balance*, in astronomy, one of the twelve signs of the zodiac, the sixth in order; so called because when the sun enters it, the days and nights are equal, as if weighed in a balance.

LIBRARY, an edifice or apartment destined for holding a considerable number of books placed regularly on shelves; or, the books themselves lodged in it.

The first who erected a library at Athens was the tyrant Pisistratus, which was transported by Xerxes into Persia, and afterwards brought back by Seleucus Nicanor to Athens. Plutarch says, that under Eumenes there was a library at Pergamus that contained 200,000 books. That of Ptolemy Philadelphus, according to A. Gellius, contained 700,000, which were all burnt by Cæsar's soldiers. Constantine and his successors erected a magnificent one at Constantinople, which in the eighth century contained 300,000 volumes, and among the rest one in which the Iliad and Odyssey were written in letters of gold, on the guts of a serpent; but this library was burnt by order of Leo Isaurus. The most celebrated libraries of ancient Rome were the Ulpian and the Palatine, and in modern Rome, that of the Vatican. The foundation of the Vatican library was laid by Pope Nicholas, in the year 1450; it was afterwards destroyed in the sacking of Rome, by the constable of Bourbon, and restored by Pope Sixtus V. One of the most complete libraries in Europe, is that erected by Cosmo de Medicis; though it is now exceeded by that of the French King, which was begun by Francis I. augmented by Cardinal Richelieu, and completed by M. Colbert. The Emperor's library at Vienna, according to Lambecius, consists of 80,000 volumes, and 15,940 curious medals. The Bodleian library at Oxford exceeds that of any university in Europe, and even those of any of the sovereigns of Europe, except those of the Emperors of France and Germany, which are each of them older by a hundred years. It was first opened in 1602, and has since been increased by a great number of benefactors; indeed the Medicean library, that of Bessarion at Venice, and those just mentioned, exceed it in Greek manuscripts, but it outdoes them all in oriental manuscripts; and as to printed books, the Ambrosian at Milan, and that of Wolfenbuttle, are two of the most famous, and yet both are inferior to the Bodleian. The Cotton library consists wholly of manuscripts, particularly such as relate to the history and antiquities of England; which, as they are now bound, make about 1000 volumes.

In Edinburgh there is a good library belonging to the university, well furnished with books which are kept in good order, and cloistered up with wire doors, that none but the keeper can open. There is also a noble library of books and manuscripts belonging to the gentlemen of the law.

LIBRATION, in astronomy, an apparent irregularity of the moon's motion, whereby she seems to librate about her axis, sometimes from the east to the west, and now and then from the west to the east; so that the parts in the western limb or margin of the moon sometimes recede from the centre of the disk, and sometimes move towards it, by which means they become alternately visible and invisible to the inhabitants of the earth.

Libration *of the earth*, is sometimes used to denote the parallelism of the earth's axis, in every part of its orbit round the sun.

LICENCE, in law, an authority given to a person to do some lawful act.

A licence is a personal power, and therefore cannot be transferred to another. If the person licensed abuse the power given him, in that case he becomes a trespasser.

LICHEN, *liverwort*, a genus of the natural order of algæ, in the cryptogamia class of plants. The male receptacle is roundish, somewhat plain and shining. In the female the leaves have a farina or mealy substance scattered over them. There are about 216 species, all found in Britain. Among the most remarkable are the following:—

L. *rocella*, or orchall, as an article of commerce, is of great importance, being extremely valuable for dying wool or silk any shade of purple or crimson. L. *omphalodes* will dye wool of a brown reddish colour, or a dull but durable crimson, paler and more lasting than that of orchall. L. *Islandicus* is used by the Icelanders in their broth; they also dry it, and make it into bread, &c.

Lichen, in medicine, a *tetter* or *ringworm*, a cutaneous disease, defined by Dr. Willan, "an extensive eruption of papillæ affecting adults, connected with internal disorder usually terminating in scurf, recurrent, not contagious." The Doctor has mentioned five varieties.

LIEUTENANT, an officer who supplies the place, and discharges the office of a superior in his absence. Of these, some are civil, as the lords-lieutenants of kingdoms, and the lords-lieutenants of counties; and others are military, as the lieutenant-general, lieutenant-general of the artillery, lieutenant-colonel, lieutenant of artillery of the Tower, lieutenants of horse, foot, ships of war, &c.

Lieutenant, *lord of Ireland*, is properly a viceroy, and has all the state and grandeur of a king of England, except being served upon the knee. He has the power of making war and peace, of bestowing all the offices under the government, of dubbing knight, and of pardoning all crimes except high treason; he also calls and prorogues the parliament, but no bill can pass without the royal assent. He is assisted in his government by a privy-council; and, on his leaving the kingdom, he appoints the lords of the regency, who govern in his absence.

- **Lieutenants**, *lords of counties*, are officers who, upon any invasion or rebellion, have power to raise the militia, and to give commissions to colonels and other officers, to arm and form them into regiments, troops, and companies. Under the lords-lieutenants are deputy-lieutenants who have the same power; these are chosen by the lords-lieutenants out of the principal gentlemen of each county, and presented to the king for his approbation.

Lieutenant *general*, is an officer next in rank to the general; in battle, he commands one of the wings; in a march, a detachment, or a flying-camp; also a quarter, at a siege, or one of the attacks, when it is his day of duty.

Lieutenant *of a ship of war*, the officer next in rank and power to the captain; of these there are several in a large ship, who take precedence according to the dates of their first commissions.

LIFE-annuities. See **Annuities.**

Life-estates are of two kinds, such as are created by the act of the parties, or such as are created by the operation of the law, as estates by courtesy or dower. 2 Black. 120.

Estates for life, created by deed or grant, are, where a lease is made of lands or tenements to a man, to hold for the term of his own life, or for that of another person, or for more lives than one; in any of which cases, he is called tenant for life; only when he holds the estate by the life of another, he is usually termed tenant pour auter vie, for another's life.

LIGAMENT. See **Anatomy.**

LIGATURE. See **Surgery.**

LIGHT. See **Optics.**

Light, *instantaneous*. An apparatus of a very simple construction has recently been offered to the public, which may be said to be free from all those objections to which the various contrivances hitherto invented for this purpose are more or less liable. The fire-boxes, although certainly superior to the phosphorus boxes, are very liable to be out of order, both by their imbibing moisture from the atmosphere, and the dispersion of the acid; but in the newly invented instantaneous light apparatus no kind of inconvenience or danger can occur, except by the most inexcusable negligence.

The following is a description of this useful instrument, as fitted up in its simplest form by Mr. Garden, operative chemist, London. A and B, fig. 1, plate XXVII, are two glass vessels fitted together by grinding the upper one at the neck, which is open at the top and furnished with a perforated stopper, to prevent the spilling of the acid, and also to permit the free entrance and escape of atmospheric air. The lower extremity of this vessel terminates in an open tube which reaches nearly to the bottom of the vessel B. The vessel B is provided with a side opening, to which are attached a brass cap with a stop-cock and jet, and also a small immoveable cup fixed to a wire, which slides in a collar fixed upon the stop-cock; the use of this collar is to afford the means of adjusting the cup at different distances from the orifice of the jet, which will occasionally become necessary, A the quantity of gas in the apparatus varies. as little experience will best teach the art of this adjustment.

The glass tube of the vessel A carries a cylinder of zinc, *a e* which is supported by a piece of cork fitted to the extremity of the tube

To charge and use the apparatus. Fill the lower glass B up to the part marked by the dotted line with diluted sulphuric acid (made by mixing together, in a stone-ware jug, one ounce, by measure, of sulphuric acid, sp. gr. 1850, with a wine pint of water), and connect the upper one with it, as represented in the figure, closing at the same time the stop-cock *y*; gas will now begin to be formed, in consequence of the action of the acid upon the metal *a e*, which surrounds the glass tube *a b*, and will occupy the lower part of the vessel B, causing the liquid to ascend into A, until one surface of the liquid appears near the part shewn by the elliptical line, and the other at a level with the bottom of the metallic cylinder *a e*. In this state the apparatus is ready for use.

If the stop-cock *y* be now opened, a stream of gas will issue from the orifice of the jet *c*; and falling into the cup *d* (which contains a fragment or two of spongy platina for igniting the gas), will quickly be kindled, and burn with a pale lambent flame, at which a piece of paper or a wax taper may instantly be lighted: the cock is then to be closed. If the experiment of thus inflaming portions of the gas be frequently and quickly repeated, a part of the liquid, which had been raised into A by the elasticity of the gas produced in B, will be found to have again descended, and this quantity will be equal to that of the gas which has escaped by the jet *c*; but as the liquid which has in this manner descended into the lower vessel will come into contact with a portion of the metallic cylinder, a new portion of gas will speedily be produced, and occasion the return of a corresponding portion of liquid into the upper vessel. In this manner the instrument will continue to replenish itself, and will never cease to furnish a regular and steady supply of gas until the whole of the acid liquor becomes saturated with metal, and can dissolve no more, or until all the metal be dissolved; neither of these circumstances however can happen for a considerable time, even with frequent and daily use. It may be proper to mention, that the cup *d*, which contains the igniting substance, should always, when not in use, be carefully closed by its cover, so as to prevent the contact of moisture or particles of dust; but if, by any accident, it should acquire damp, and lose the power of inflaming the gas, it may generally be restored by heating it upon the blade of a knife over the clear flame of a candle, or still better over that of a spirit lamp; if this does not succeed, it must be rejected, and a fresh portion from the small vial substituted in its place.

After long and continued use, the small orifice of the jet *c* will be liable to become partially closed up, by the action of the burning gas, or the accidental accession of particles of dust; but this may be remedied in a moment, by unscrewing the jet and passing through it a fine sewing needle, as shewn in the enlarged sketch of the jet, fig. 2.

Light *from plants*. In Sweden a very curious phenomena has been observed on certain flowers by M. Haggern, lecturer on natural history. One evening he perceived a faint flash of light repeatedly dart from a marigold. Surprised at the appearance, he resolved to examine it with attention; and, to be assured it

was no deception of the eye, he placed a man near him, to make a signal at the moment when he observed the light. They both saw it constantly at the same moment. The light was most brilliant on marigolds of an orange or flame colour; but scarcely visible on pale ones. To discover whether some little insects or phosphoric worms might not be the cause of this appearance, the flowers were carefully examined, even with a microscope, without any such thing being found. From the rapidity of the flash, and other circumstances, it may be inferred that there is something of electricity in this phenomenon.

LIGHTFOOTIA, a genus of the class and order polygamia dioecea. The calyx is four-leaved; cor. none; fem. and her. stigma sessile; berry umbilicated. There are three species, shrubs of the E. Indies.

LIGHT-HOUSE, a building erected upon a cape or promontory on the sea-coast, or upon some rock in the sea, and having on its top in the night-time a great light formed by lamps, constantly attended by some careful person, so as to be seen at a great distance from the land. It is used to direct the shipping on the coast, that might otherwise run a-shore, or steer an improper course, when the darkness of the night and the uncertainty of currents, &c. might render their situation with regard to the shore extremely doubtful.

LIGHTNING, the name given to those explosions of electricity that take place in the atmosphere during a thunder-storm. See ELECTRICITY.

LIGHTS: stopping lights of any house is a nuisance, for which an action will lie, if the house is an ancient house, and the lights ancient lights: but stopping a prospect is not, being only matter of delight, not of necessity.

LIGUSTICUM, *lovage*; a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. There are eight species, of which the most remarkable are, the levisticum, or common, and the Scoticum, or Scots, lovage. The first is a native of the Appenine mountains in Italy. The second is a native of Scotland, and grows near the sea in various parts of the country.

LIGUSTRUM, *privet*, a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking under the 44th order, sepiariæ. Of the common there are two varieties, the deciduous and the evergreen. They are hardy plants, rising from ten to fifteen feet high. They are easily propagated by seed, layers, suckers, or cuttings. They are used for making hedges. The purple colour upon cards is prepared from the berries. The leaves are bitter and slightly astringent. Oxen, goats, and sheep, eat the plant; horses refuse it.

LIKE, in geometry, &c. denotes the same with similar.

LILAC, in botany, a genus of trees, otherwise called syringa. See SYRINGA.

LILATE, the mineral LEPIDOLITE.

LILIUM, the *lily*; a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is hexapetalous, and campanulated; the capsules connected by small cancellated hairs. There are eleven species; all of them bulbous-rooted, herbaceous, flowery perennials, rising with erect annual stalks three or four feet high, garnished with long narrow leaves, and terminated by fine clusters of bell-shaped, hexapetalous flowers of great beauty.

LIMAX, the *slug*, or naked snail; a genus of insects belonging to the order of vermes mollusca. The body is oblong, fitted for crawling, with a kind of muscular coat on the upper part, and the belly is plain. They have four tentacula, or horns, situated above the mouth, which they extend or retract at pleasure. This reptile is always destitute of shell; but besides that, its skin is more clammy, and of a greater consistency, than that of the snail: the black naked slug has a furrowed cloak, almost as thick and as hard as leather, under which it withdraws its head as within a shell. There are eight species, distinguished entirely by their colour; as the black slug, the white slug, the reddish slug, the ash-coloured slug, &c. The black slug is hermaphrodite. A black slug, powdered over with snuff, salt, or sugar, falls into convulsions, casts forth all its foam, and dies.

LIME, one of those earthly substances, which exist in every part of the known world. It is found purest in lime-stone, marble and chalk. None of these substances are lime, but are capable of becoming so by burning in a white heat. Pure lime is of a white colour, moderately hard, but easily reduced to a powder. If water be poured on newly-burnt lime, it swells and falls to pieces, and is soon reduced to a very fine powder. In the mean time so much heat is produced, that part of the water flies off in vapour. If the quantity of lime slacked be great, the heat produced is sufficient to set fire to combustibles. In this manner, vessels loaded with lime have sometimes been burnt. When great quantities of lime are slacked in a dark place, not only heat but light also is emitted, as Mr. Pelletier has observed. When slacked lime is weighed, it is found to be heavier than it was before. This additional weight is owing to the combination of part of the water with the lime. The smell perceived during the slacking of lime is owing to a part of that earth being elevated along with the vapour of the water; as evidently appears from this circumstance, that vegetable blues exposed to this vapour are converted to green. Limestone and chalk, though they are capable of being converted into lime by burning, possess hardly any of the properties of that active substance. They are tasteless, scarcely soluble in water, and do not perceptibly act on animal bodies.

Lime is not acted on by light, neither does it combine with oxygen. Sulphur and phosphorus are the only simple combustibles with which it unites.

Lime does not combine with alkalis. The affinities of lime are arranged by Bergmann in the following order

Oxalic acid
Sulphuric
Tartaric
Succinic
Phosphoric
Saclactic
Nitric
Muriatic
Suberic
Fluoric
Arsenic
Lactic
Citric
Benzoic
Sulphurous
Acetic
Boracic
Carbonic
Prussic

Quicklime, in the act of becoming mild, prepares soluble out of insoluble matter. It is upon this circumstance that the operation of lime in the preparation for wheat crops depends; and its efficacy in fertilizing peats, and in bringing into a state of cultivation all soils abounding in hard roots or dry fibres, or inert vegetable matter.

The solution of the question, whether quicklime ought to be applied to a soil, depends upon the quantity of inert vegetable matter that it contains. The solution of the question, whether marle, mild lime, or powdered limestone, ought to be applied, depends upon the quantity of calcareous matter already in the soil. All soils are improved by mild lime, and ultimately by quicklime, which do not effervesce with acids; and sands more than clays.

When a soil, deficient in calcareous matter, contains much *soluble* vegetable manure, the application of quicklime should always be avoided, as it either tends to decompose the soluble matters by uniting to their carbon and oxygen so as to become mild lime, or it combines with the soluble matters, and forms compounds having less attraction for water than the pure vegetable substance.

The case is the same with respect to most animal manures; but the operation of the lime is different in different cases, and depends upon the nature of the animal matter. Lime forms a kind of insoluble soap with oily matters, and then gradually decomposes them by separating from them oxygen and carbon. It combines likewise with the animal acids, and probably assists their decomposition by abstracting carbonaceous matter from them combined with oxygen; and consequently it must render them less nutritive. It tends to diminish likewise the nutritive powers of albumen from the same causes; and always destroys, to a certain extent, the efficacy of animal manures, either by combining with certain of their elements, or by giving to them new arrangements. Lime should never be applied with animal manures, unless they are too rich, or for the purpose of preventing noxious effluvia. It is injurious when mixed with any common dung, and tends to render the extractive matter insoluble.

In those cases in which fermentation is useful to produce nutriment from vegetable substances, lime is always efficacious, as with tanners' bark.

There are two modes in which lime acts as a cement: in its combination with water, and in its combination with carbonic acid.

When quicklime is rapidly made into a paste with water, it soon loses its softness, and the water and the lime form together a solid coherent mass, which consists of one part of water to three parts of lime. When hydrate of lime, whilst it is consolidating, is mixed with red oxide of iron, alumina, or silica, the mixture becomes harder, and more coherent than when lime alone is used; and it appears that this is owing to a certain degree of chemical attraction between hydrate of lime and these bodies; and they render it less liable to decompose by the action of the carbonic acid in the air, and less soluble in water.

The basis of all cements that are used for works which are to be *covered with water*, must be formed from hydrate of lime; and the lime made from impure limestones answers this purpose very well. Puzzolana is composed principally of silica, alumina, and oxide of iron; and it is used mixed with lime to form cements intended to be employed under water. Mr. Smeaton, in the construction of the Eddystone light-house, used a cement composed of equal parts by weight of slacked lime and puzzolana. Puzzolana is a decomposed lava.

Tarras, which was formerly imported in considerable quantities from Holland, is a mere decomposed basalt: two parts of slacked lime and one part of tarras form the principal part of the mortar used in the great dykes of Holland. Substances which will answer all the ends of puzzolana and tarras are abundant in the British Islands. An excellent red tarras may be procured in abundance from the Giant's Causeway; and decomposing basalt is abundant in many parts of Scotland, and also in the northern districts of England in which coal is found.

Parker's cement, and cements of the same kind made at the alum works of Lord Dundas, and Lord Mulgrave, are mixtures of calcined ferruginous, siliceous, and aluminous matter, with hydrate of lime. See Cement.

The cements which act by combining with carbonic acid, or the common mortars, are made by mixing together slacked lime and sand. These mortars at first solidify as hydrates, and are slowly converted into carbonate of lime by the action of the carbonic acid of the air. Mr. Tennant found that a mortar of this kind, in three years and a quarter, had regained 63 per cent. of the carbonic acid gas, which constitutes the definite proportion of carbonate of lime. The rubbish of mortar from houses owes its power to benefit lands principally to the carbonate of lime it contains, and the sand in it; and its state of cohesion renders it particularly fitted to improve clayey soils. The hardness of the mortar in very old buildings, depends upon the perfect conversion of all its parts into carbonate of lime. The purest limestones are the best adapted for making this kind of mortar: the magnesian limestones make excellent water cements, but act with too little energy upon carbonic acid gas to make good common mortar.

The Romans, according to Pliny, made their best mortar a year before it was used; so that it was partially combined with carbonic acid gass before it was employed.

In burning lime there are some particular precautions required for the different kinds of limestones. In general, one bushel of coal is sufficient to make four or five bushels of lime. The magnesian limestone requires less fuel than the common limestone. In all cases in which a limestone containing much aluminous or siliceous earth is burnt, great care should be taken to prevent the fire from becoming too intense; for such lime easily vitrifies, in consequence of the affinity of lime for silica and alumina. And as in some places there are no other limestones than such as contain other earths, it is important to attend to this circumstance. A moderately good lime may be made at a low red heat; but it will melt into a glass at a white heat. In limekilns for burning such lime, there should be always a damper.

In general, when limestones are not magnesian, their purity will be indicated by their

loss of weight in burning; the more they lose, the larger is the quantity of calcareous matter they contain. The magnesian limestones contain more carbonic acid than the common limestones; and all of them lose more than half their weight by calcination.

Lime-kilns, are buildings in which limestone is converted into lime by the operation of heat.

Limestone, is the native indurated carbonate of lime; it is usually more or less bluish from the presence of iron; and of a granulated fracture.

LIMIT, in a restrained sense, is used by mathematicians for a determinate quantity to which a variable one continually approaches. In algebra, the term limits is applied to two quantities, one of which is greater, and the other less, than another quantity.

LIMITATION, a certain time prescribed by statute, within which an action must be brought. The time of limitation is twofold; first in writs, by divers acts of parliaments; secondly to make a title to any inheritance, and that is by the common law.

Limitation on penal statutes. All actions, suits, bills, indictments, or informations, for any forfeiture limited to the king, his heirs or successors only, shall be brought within two years after the offence committed, and not after; and all actions, &c. except the statutes of tillage, the benefit and suit whereof is or shall be by the said statute limited to the king, his heirs, or successors, shall be brought by any person that may lawfully sue for the same, within one year next after the offence committed; and in default of such pursuit, then the same shall be brought for the king's majesty, his heirs or successors, any time within the two years, after that year is ended: and it is provided, that where a shorter time is limited by any penal statute, the prosecution must be within that time.

All actions of trespass, of assault, battery, wounding, imprisonment, or any of them, are to be commenced within four years next after the cause of such actions or suits, and not after. All actions of trespass, *quare clausum fregit;* all actions of trespass, detinue, trover, and replevin; all actions of account, and upon the case, (other than such accounts as concern the trade of merchandise between merchant and merchant;) all actions of debt, grounded upon any lending, or contract without speciality, (that is, not being by deed or under seal;) all actions of debt for arrearages of rent; and all actions of assault, menace, battery, wounding, and imprisonment, shall be commenced within the time and limitation as followeth, and not after: that is to say, the said actions upon the case (other than for slander,) and the said actions for account, and the said actions for trespass, debt, detinue, and replevin, and the said action for trespass *quare clausum fregit*, within six years after the cause of such action. In all these statutes there is an exception in relation to infants, lunatics, and femes coverts, allowing them a further time after they are in a situation which enables them to sue. As to the exception with respect to merchants' accounts, it extends to actions on accounts current only, in which the giving credit on one side is an acknowledgment of the debt on the other; but when the account is settled between merchant and merchant, it must be sued for like any other debt; and if all the articles are on one side, the account is not taken out of the statute. An acknowledgment of the debt prevents the operation of the statute of limitations, and also a payment upon account: but as it is convenient that suits should not be delayed so long that vouchers cannot be produced, settlements should regularly be enforced. A writ also may be sued out to save the statute of limitation, as it is called, and though never sued, yet if it is regularly entered, and continued upon the record, the suit may be effectually prosecuted long after, and being commenced within time, the action may be maintained out. This is in conscience rather a mode of evading the statute.

LIMNING, the art of painting in water colours, in contradistinction to painting which is done in oil colours. See Painting.

LIMODORUM, a genus of the gynandria diandria class of plants, the flower of which consists of five oblong petals, and the nectarium hollow, and formed of a single leaf: the fruit is a columnar unilocular capsule, containing a great number of very small seeds. There are thirteen species, bulbs of America, &c.

LIMONIA, a genus of the decandria monogynia class and order. There are seven species, trees of the East Indies, &c.

LIMOSELLA, a genus of the didynamia angiospermia class of plants: the flower consists of one erect petal, divided into five segments; fruit is an unilocular capsule, with a great many seeds. Two species, annuals of the Cape.

LINCONIA, a genus of the class and order pentandria digynia. There is one species, a shrub of the Cape.

LINDERA, a genus of the class and order hexandria monogynia. There is one species, a shrub of Japan.

LINDERNIA, a genus of the class and order didynamia angiospermia. There are three species, annuals of America.

LINE, in geometry, a quantity extending in length only, without any breadth or thickness. It is formed by the flux or motion of a point. See Fluxion and Geometry.

Lines, considered as to their positions, are either parallel, perpendicular, or oblique, the construction and properties whereof see under Parallel, &c.

Lines, in perspective, are, 1, Geometrical line, which is a right line drawn in any manner on the geometrical plane. 2. Terrestrial line, or fundamental line, is a right line wherein the geometrical plane, and that of the picture or draught, intersect one another.

Line of direction on the earth's axis, in the Pythagorean system of astronomy, the line connecting the two poles of the ecliptic and of the equator, when they are projected on the plane of the former.

Line of direction. See Mechanics.

Line of gravitation of any heavy body, a line drawn through its centre of gravity, and according to which it tends downwards.

Lines on the plain scale, are the line of chords, line of sines, line of tangents, line of secants, line of semitangents, line of leagues; the construction and application of which see under the words Scale, Sailing, &c.

LINES on Gunter's scale. See GUNTER'S SCALE.

LINES, in fortification, are those of approach, capital, defence, circumvallation, contravallation of the base, &c.

To LINE a work, signifies to strengthen a rampart with a firm wall: or to encompass a parapet or moat with good turf, &c.

LINE, in the art of war, is understood of the disposition of an army, ranged in order of battle, with the front extended as far as may be, that it may not be flanked.

LINE *of battle*, is also understood of the disposition of a fleet on the day of engagement.

Ship of the LINE, a vessel large enough to be drawn up in the line, and to have a place in a sea-fight.

LINE, also denotes a French measure, containing the twelfth part of an inch, or the hundred and forty-fourth part of a foot.

LINEAR NUMBERS in mathematics, such as have relation to length only: such is a number which represents one side of a plane figure.

LINEAR PROBLEM, that which may be solved geometrically, by the intersection of two right lines.

LINEN, in commerce, a well known kind of cloth, chiefly made of flax.

LING. See GADUS.

LINNÆA, a genus of the class and order didynamia angiospermia. The cal. is double; the cor. bell-shaped; the berry dry, three-celled. There is one species, an herb of Sweden.

LINNET. See FRINGILLIA.

LINSEED, the seed of the plant linum. See LINUM.

LINSPINS, in the military art, small pins of iron, which keep the wheel of a cannon or waggon on the axle-tree, to keep the wheel from falling off.

LINSTOCK, in the military art, a wooden staff, about three feet long, upon one end of which is a piece of iron which divides in two, turning from one another, having each a place to receive a match, and a screw to keep it fast. The other end is pointed, and shod with iron, to stick in the ground. It is used by gunners to light the port-fire at, with which the guns are fired.

LINT, *linum*, from the flux of which linen is made.

In surgery, the term lint denotes the scrapings of linen used in dressing wounds, and made up in various forms, as tents, dossils, pledgets, &c.

LINUM, in botany, *flax*, a genus of the pentandria pentagynia class and order, natural order of gruinales. Essential character:—calyx five-leaved; petals five; capsule ten-valved, ten-celled; seeds solitary. There are twenty-five species. The several species of flax are mostly herbaceous, some are fruticose, or woody at bottom; two are shrubby, and one arboreous; leaves generally alternate; flowers solitary and axillary; corolla commonly blue, sometimes fading to white, and in some yellow. Flax is found wild in many parts of Europe, in corn fields; in England it is, perhaps, doubtful whether it be aboriginal. It is common in the western counties, not only in corn-fields, but in pastures and on downs.

LION. See FELIS.

LIONCELLES, in heraldry, a term used for several lions borne in the same court of arms.

LIP, *hare*, a disorder in which the upper lip is in a manner slit or divided, so as to resemble the upper lip of a hare, whence the name.

LIPPIA, a genus of the didynamia gymnospermia class and order. The cal. is four-toothed; the caps. one-celled, three-valved, two-seeded; seed one, two-celled. There are five species, shrubs of America.

LIQUEFACTION. See FLUIDITY.

LIQUOR *of flints*. Alkalis have a powerful action on silica: they combine in different proportions; two or three parts of potash, with one of silica, give a compound, which is deliquescent in the air, and soluble in water. This was formerly distinguished by the name of liquor of flints, but it is now denominated silicated alkali.

LIQUORICE. See GLYCIRRHIZA.

LIRIODENDRON, the *tulip tree*, a genus of the polygynia order, in the polyandria class of plants; and in the natural method ranking under the 52d order, coadunatæ. The calyx is triphyllous; there are nine petals; and the seeds imbricated in such a manner as to form a cone. There are two species, viz. L. tulipifera, common tulip tree; and L. lillifera; the former is a native of North America, where it is a tree of the first magnitude, and is generally known in all the English settlements by the name of poplar.

LIST, in commerce, the border of cloth or stuff, serving not only to shew their quality, but to preserve them from being torn in the operation of fulling, dyeing, &c. List is used for a variety of purposes, but chiefly by gardeners for securing their wall-trees.

LITA, a genus of the class and order pentandria monogynia. There are two species, herbs of Guiana.

LITERARY *property*. Authors, it should seem had, by the common law, the sole and exclusive copyright remaining in themselves or their assigns in perpetuity, after having printed and published their compositions. This, as a common law right, was strangely questioned by some of our judges, who studied special pleading more than common sense. But by statute 8 Anne, c. 19, it is secured to them for fourteen years, from the day of publishing; and after the end of fourteen years, the sole right of printing or disposing of copies, shall return to the authors, if then living, for other fourteen years. This statute, it has been held, restrains the right of the author and his assigns to the fourteen or the twenty-eight years, whatever it might have been at the common law. A penalty on each sheet found in the possession of a party pirating a work, is inflicted by the statute, 9, Anne, c. 19; and, in order to entitle the plaintiff to recover this penalty, the book must have been entered at Stationers' Hall. But an author whose work has been pirated, may maintain an action for damages merely without having so entered his book. When an author transfers all his right or interest in a publication to another, and happens to survive the first fourteen years, the second term will result to his assignee, and not to himself.

LITHARGE, an oxide of lead. See LEAD.

LITHIA. A new alkali. It was discovered by M. Arfredson, a young chemist of great

merit, employed in the laboratory of M. Berzelius. It was found in a mineral from the mine of Uten in Sweden, called *petalite* by M. D'Andrada, who first distinguished it. Sir H. Davy demonstrated by voltaic electricity, that the basis of this alkali is a metal, to which the name of *lithium* has been given.

Lithia may be obtained by fusing petalite with potash, dissolving the whole in muriatic acid, evaporating to dryness, and digesting in alcohol. The muriate of lithia being very soluble in that fluid, is taken up, while the other salts remain. By a second evaporation and solution in alcohol, it is obtained perfectly pure. The muriate is itself a salt very characteristic of the alkali. It may easily be decomposed by carbonate of silver; and the carbonate thus procured, when treated with lime, yields pure lithia. Caustic lithia has a very sharp burning taste. It destroys the cuticle of the tongue like potash. It does not dissolve with great facility in water, and appears not to be much more soluble in hot than in cold water. In this respect it has an analogy to lime. Heat is evolved during its solution in water. When exposed to the air it does not attract moisture, but absorbs carbonic acid, and becomes opaque. When exposed for an hour to a white heat in a covered platinum crucible, its bulk does not appear to be diminished; but it has absorbed a quantity of carbonic acid.

LITHIC-*acid*. This was discovered about the year 1776 by Scheele, in analyzing human calculi, of many of which it constitutes the greater part, and of some, particularly that which resembles wood in appearance, it forms almost the whole. It is likewise present in human urine, and in that of the camel; and Dr. Pearson found it in those arthritic concretions commonly called chalkstones, which Mr. Tennant has since confirmed. It is often called *uric* acid.

The following are the results of Scheele's experiments on calculi, which were found to consist almost wholly of this acid. 1. Dilute sulphuric acid produced no effect on the calculus, but the concentrated dissolved it; and the solution, distilled to dryness, left a black coal, giving off sulphurous acid fumes. 2. The muriatic acid, either diluted or concentrated, had no effect on it even with ebullition. 3. Dilute nitric acid attacked it cold; and with the assistance of heat produced an effervescence and red vapour, carbonic acid was evolved, and the calculus was entirely dissolved. The solution was acid, even when saturated with the calculus, and gave a beautiful red colour to the skin in half an hour after it was applied; when evaporated, it became of a blood-red, but the colour was destroyed by adding a drop of acid: it did not precipitate muriate of barytes, or metallic solutions, even with the addition of an alkali; alkalis rendered it more yellow, and if superabundant, changed it by a strong digest- [illegible] of copper green, nitrate of silver grey, superoxygenated muriate of mercury, and solutions of lead and zinc, white. Lime water produced in the nitric solution a white precipitate, which dissolved in the nitric and muriatic acids without effervescence, and without destroying their acidity. Oxalic acid did not precipitate it. 4. Carbonate of potash did not dissolve it, either cold or hot, but a solution of perfectly pure potash dissolved it even cold. The solution was yellow; sweetish to the taste; precipitated by all the acids, even the carbonic; did not render lime water turbid; decomposed and precipitated solution of iron brown, of copper grey, of silver black, of zinc, mercury, and lead, white; and exhaled a smell of ammonia. 5. About 200 parts of lime water dissolved the calculus by digestion, and lost its acrid taste. The solution was partly precipitated by acids. 6. Pure water dissolved it entirely, but it was necessary to boil for some time 360 parts with one of the calculus in powder. This solution reddened tincture of litmus, did not render lime water turbid, and on cooling deposited in small crystals almost the whole of what it had taken up. 7. Seventy-two grains distilled in a small glass retort over an open fire, and gradually brought to a red heat, produced water of ammonia mixed with a little animal oil, and a brown sublimate, weighing 28 grains, and 12 grains of coal remained, which preserved its black colour on red-hot iron in the open air.

LITHOMARGE, in mineralogy, is a species of the clay genus, and divided by Werner and others into two sub-species, viz. the friable and the indurated. Friable lithomarge or rock-marrow is white and massive; it occurs likewise as a crust, and disseminated. Its lustre is feebly glimmering, is generally coherent, feels greasy, and adheres to the tongue. It is found in large quantities in the Saxon tin veins. Indurated lithomarge is commonly white, but with many varieties of colour. It is found in many parts of Germany, and occurs in veins of porphyry, gneiss, and serpentine.

LITHOTOMY, in surgery, the operation by which a calculus is removed from the bladder.

LITMUS, in chemistry, a substance, the tincture of which is extremely useful, as a test of the presence of an acid or alkali. All acids and salts, with an access of acid, change the natural violet purple of litmus to red; when reddened by an acid, the blue is restored by an alkali.

LITURGY, a name given to those set forms of prayer which have been generally used in the Christian church. Of these there are not a few ascribed to the apostles and fathers, but they are almost universally allowed to be spurious.

LIVER, in anatomy, a very large viscus, of a red colour, situated in the right hypochondrium, and serving for the secretion of the bile or gall. See ANATOMY.

LIVERY, in matters of dress and equipage, a certain colour and form of dress by which noblemen and gentlemen choose to distinguish their servants.

LIVERY *of seisin*, a delivery of possession of lands, tenements, or other corporeal thing (for of things incorporeal there can be no seisin) to one that has right.

Livery of seisin must be on the land in the presence of two witnesses, and was anciently used to give publicity to gifts or transfers of land. It is now necessary, in order to complete a feoffment, and to make good a lease for life or grant of the freehold to commence at a future day. See ESTATE, LEASE. Where there is land and a house, it must be made in the house that being the principal.

LIVERYMEN, of London, are a number of men chosen from among the freemen of each company. Out of this body the common council, sheriff, and other superior officers for the government of the city are elected, and they alone have the privilege of giving their votes for members of parliament; from which the rest of the citizens are excluded.

LIVES, or insurance of Lives. See Insurance, and Life.

LIZARD. See Lacerta.

LOAD, or Lode, in mining, a word used, especially in the tin-mines, for any regular vein or course, whether metallic or not; but most commonly load means a metallic vein.

LOAMS. See Agriculture.

LOANS, in political economy, sums of money, generally of large amount, borrowed from individuals or public bodies, for the service of the state. They are either compulsory, in which case they may be more properly termed requisitions; or voluntary, which is the only mode that can be frequently resorted to with advantage. Loans are sometimes furnished by public companies as a consideration for peculiar privileges secured to them; but are much more commonly advanced by individuals on a certain interest being allowed for the use of the money, either for a term of years, or until the principal shall be repaid.

The practice of borrowing money, for defraying part of the extraordinary expences in time of war, had been adopted in other countries long before it was introduced into Great Britain; but it has been carried to a far greater extent here than in any other state; and the facility with which the government has been enabled to raise the largest sums, has arisen entirely from the strict punctuality with which it has constantly made good all pecuniary engagements. The chancellor of the exchequer is the officer who usually conducts negociations of this kind on the part of the government, and the agreement is, afterward confirmed by parliament.

LOBE, in anatomy, any fleshy protuberant part, as the lobes of the lungs, lobes of the ears, &c.

LOCAL, in law, something fixed to the freehold, or tied to a certain place; thus, real actions are local, since they must be brought in the country where they lie, and local customs are those peculiar to certain countries and places.

Local *problem*, among mathematicians, such a one as is capable of an infinite number of different solutions, by reason that the point which is to resolve the problem may be indifferently taken within a certain extent.

LOCK, a well-known instrument, and reckoned the masterpiece in smithery; a great deal of art and delicacy being required in contriving and varying the wards, springs, bolts, &c. and adjusting them to the places where they are to be used, and to the various occasions of using them. From the various structure of locks, accommodated to their different intentions, they acquire various names. Those placed on outer doors are called stock-locks; those on chamber doors, spring locks; those on trunks, trunk-locks, padlocks, &c. Of these the spring-lock is the most considerable, both for its frequency and the curiosity of its structure.

A treatise upon this subject has been published by Mr. Joseph Bramah, who begins with observing, that the principle on which all locks depend, is the application of a lever to an interior bolt, by means of a communication from without; so that, by means of the latter, the lever acts upon the bolt, and moves in such a manner as to secure the lid or door from being opened by any pull or push from without. The security of locks in general, therefore, depends on the number of impediments we can interpose betwixt the lever (the key) and the bolt which secures the door; and these impediments are well known by the name of wards, the number and intricacy of which alone are supposed to distinguish a good lock from a bad one. If these wards, however, do not in an effectual manner preclude the access of all other instruments besides the proper key, it is still possible for a mechanic of equal skill with the lockmaker to open it without the key, and thus to elude the labour of the other. "As nothing (says Mr. Bramah) can be more opposite in principle to fixed wards than a lock which derives its properties from the motion of all its parts, I determined that the construction of such a lock should be the subject of my experiment." In the prosecution of this experiment, he had the satisfaction to find that the least perfect of all his models fully ascertained the truth and certainty of his principle. The exclusion of wards made it necessary to cut off all communication between the key and the bolt; as the same passage which (in a lock simply constructed) would admit the key, might give admission likewise to other instruments. The office, therefore, which in other locks is performed by the extreme point of the key, is here assigned to a lever, which cannot approach the bolt till every part of the lock has undergone a change of position.

Lock, or, **Wier**, in inland navigations, the general name for all those works of wood or stone, made to confine and raise the water of a river. But the term lock is more particularly appropriated to express a kind of canal inclosed between two gates; the upper called by workmen the sluice-gate, and the lower called the flood-gate. These serve in artificial navigations to confine the water, and render the passage of boats easy in passing up and down the stream.

LOCUS *geometricus*, denotes a line by which a local or indeterminate problem is solved.

A locus is a line, any point of which may equally solve an indeterminate problem. Thus, if a right line suffice for the construction of the equator, it is called *locus ad rectum.* If a circle, *locus ad circulum:* if a parabola, *locus ad parabolam:* if an ellipsis, *locus ad ellipsin:* and so of the rest of the conic sections.

LOCUST. See Gryllus.

LODGMENT, in military affairs, is a work raised with earth, gabions, fascines, woolpacks, or mantelets, to cover the besiegers from the enemy's fire, and to prevent their losing a place which they have gained, and are resolved, if possible, to keep.

LOG, in naval affairs, is a flat piece of wood shaped somewhat like a flounder, with a piece of lead fastened to its bottom, which makes it stand or swim upright in the water. To this log is fastened a long line, called the log-line; and this is commonly divided into certain

spaces fifty feet in length by knots, which are pieces of knotted twine inreeved between the strands of the line; which shew, by means of a half-minute glass, how many of these spaces or knots are run out in half a minute. They commonly begin to be counted at the distance of about 10 fathoms or 60 feet from the log; so that the log, when it is hoven overboard, may be out of the eddy of the ship's wake before they begin to count: and for the ready discovery of this point of commencement, there is commonly fastened at it a red rag.

The log being thus prepared, and hoven over board from the poop, and the line veered out by the help of a reel, as fast as the ship sails from it, will shew how far the ship has run in a given time, and consequently her rate of sailing. Hence it is evident, that as the distance of the knots bears the same proportion to a mile as half a minute does to an hour, whatever number of knots the ship runs in half a minute, the same number of miles she will run in an hour.

Log-board, a table generally divided into five columns, in the first of which is entered the hour of the day; in the second the course steered; in the third the number of knots run off the reel each time of heaving the log; in the fourth, from what point the wind blows; and in the fifth, observations on the weather, variation of the compass, &c.

Log-book, a book ruled in columns like the log-board, into which the account on the log-board is transcribed every day at noon.

LOGARITHMS are numbers so contrived and adapted to other numbers, that the sums and differences of the former shall correspond to, and shew the products and quotients of the latter.

Or, more generally, logarithms are the numerical exponents of ratios; or a series of numbers in arithmetical progression, answering to another series of numbers in geometrical progression. Thus,

0, 1, 2, 3, 4, 5, Indices, or logarithms.
1, 2, 4, 8, 16, 32, Geometric progression.

Or,

0, 1, 2, 3, 4, 5, Indices, or logarithms.
1, 3, 9, 27, 81, 243, Geometric progression

Or,

0, 1, 2, 3, 4, 5, Ind. or log.
1, 10, 100, 1000, 10000, 100000, Geo. pro.

Where it is evident that the same indices serve equally for any geometric series; and consequently there may be an endless variety of systems of logarithms to the same common numbers, by only changing the second term, 2, 3, or 10, &c. of the geometrical series.

It is also apparent, from the nature of these series, that if any two indices be added together, their sum will be the index of that number which is equal to the product of the two terms, in the geometric progression, to which those indices belong.

Thus, the indices 2 and 3, being added together, are = 5; and the numbers 4 and 8, or the terms corresponding with those indices, being multiplied together, are = 32, which is the number answering to the index 5.

And, in like manner, if any one index be subtracted from another, the difference will be the index of that number, which is equal to the quotient of the two terms to which those indices belong.

Thus the index 6, minus the index 4, is = 2; and the terms corresponding to those indices are 64 and 16, whose quotient is = 4; which is the number answering to the index 2.

For the same reason, if the logarithm of any number is multiplied by the index of its power, the product will be equal to the logarithm of that power.

Thus, the index or logarithm of 4, in the above series, is 2; and if this number is multiplied by 3, the product will be = 6; which is the logarithm of 64, or the third power of 4.

And if the logarithm of any number is divided by the index of its root, the quotient will be equal to the logarithm of that root.

Thus, the index or logarithm of 64 is 6; and if this number is divided by 2, the quotient will be = 3; which is the logarithm of 8 or the square root of 64.

The logarithms most convenient for practice are such as are adapted to a geometric series, increasing in a tenfold proportion, as in the last of the above forms, and are those which are to be found, at present, in most of the common tables upon this subject.

The distinguishing mark of this system of logarithms is, that the index, or logarithm, of 1 is 0; that of 10, 1; that of 100, 2: that of 1000, 3, &c. And in decimals the logarithms of 1 is —1 that of .01, —2; that of .001, 3, &c.

From whence it follows that the logarithm of any number between 1 and 10 must be 0 and some fractional parts, and that of a number between 10 and 100 will be one and some fractional parts; and so on for any number whatever.

And since the integral part of a logarithm is always thus readily found, it is usually called the index, or characteristic; and is commonly omitted in the tables; being left to be supplied by the operator himself, as occasion requires.

To find the logarithm of any of the natural numbers, 1, 2, 3, 4, &c. according to the method of Napier.—Take the geometrical series, 1, 10, 100, 1000, 10,000, &c. and apply it to the arithmetical series, 1, 2, 3, 4, as logarithms. 2. Find a geometric mean between 1 and 10, 10 and 100, or any other two adjacent terms of the series betwixt which the number proposed lies. 3. Between the mean, thus found, and the nearest extreme, find another geometrical mean, in the same manner; and so on, till you have arrived within the proposed limit of the number whose logarithm is sought. 4. Find as many arithmetical means, in the same order that you found the geometrical ones, and the last of these will be the logarithm answering to the number required.

Examples. Let it be required to find the logarithm of 9.

Here the numbers between which 9 lies are 1 and 10.

First, then, the log. of 10 is 1; and the log. of 1 is 0, therefore $\frac{1+0}{2} = .5$ is the arithmetical mean, and $\sqrt{(1 \times 10)} = \sqrt{10} = 3.1622777 =$ geometric mean: whence the logarithm of 3.1622777 is .5

Secondly, the log. of 10 is 1, and the log. of 3.1622777 is .5; therefore $\frac{15}{2} = .75 =$ arithmetrical mean, and $\sqrt{}\,(10 \times 3.1622777) = 5.6231182 =$ geometric mean: whence the log. of 5.6234132 is .75.

Thirdly, the log. of 10 is 1, and the log. of 5.6234132 is .75; therefore $\frac{1+75}{2} = .875 =$ arithmetical mean, and $\sqrt{}\,(10. \times 5.6234132 = 7.4989421 =$ geometrical mean; whence the log. of 7.4989421 is .875.

Of the method of using a table of logarithms.

In taking out of a table the logarithm of any number not exceeding 10000, we have the decimal part by inspection; and if to this the proper characteristic be affixed, it will give the complete logarithm required.

But if the number, whose logarithm is required, be above 10000, then find the logarithm of the two nearest numbers to it that can be found in the table, and say, as their difference : the difference of their logarithms . . the difference of the nearest number and that whose logarithm is required : the difference of their logarithms nearly; and this difference being added to, or subtracted from, the nearest logarithm, according as it is greater or less than the required one, will give the logarithm required nearly.

Thus, let it be required to find the logarithm of 367182.

The decimal part of 3671 is by the table 5647844; and of 3672 is .5649027;

$$\therefore \text{The log. of} \left\{ \begin{matrix} 367100 \text{ is } 5.5647844 \\ 367200 \text{ is } 5.5649027 \end{matrix} \right\}$$

$$\text{Their diff. } 100 \qquad .0001183 \text{ diff.}$$

$$\begin{matrix} \text{Nearest No.} \\ \text{Given No.} \end{matrix} \left\{ \begin{matrix} 367200 \\ 367182 \end{matrix} \right\}$$

$$18 \text{ diff.}$$

Therefore 100 : .0001183 : : 18 : .0000212.

And 5.5649027 — .0000212 = 5.5648815 = logarithm of 367182, nearly.

If the number consists both of integers and fractions, or is entirely fractional, find the decimal part of the logarithm as if all its figures were integral; and this, being prefixed to the proper characteristic, will give the logarithm required.

And if the given number is a proper fraction, subtract the logarithm of the denominator from the logarithm of the numerator, and the remainder will be the logarithm sought; which being that of a decimal fraction, must always have a negative index.

And, if it is a mixed number, reduce it to an improper fraction, and find the difference of the logarithms of the numerator and denominator, in the same manner as before.

In finding the number answering to any given logarithm, the index, if affirmative, will always shew how many integral places the required number consists of; and, if negative, in what place of decimals the first, or significant figure, stands; so that, if the logarithm can be found in the table, the number answering to it will always be had by inspection.

But if the logarithm cannot be exactly found in the table, find the next greater, and the next less, and then say, As the difference of these two logarithms : the difference of the numbers answering to them : : the difference of the given logarithm, and the nearest tabular logarithm : a fourth number: which added to, or subtracted from, the natural number answering to the nearest tabular logarithm, according as that logarithm is less or greater than the given one, will give the number required nearly.

Thus, let it be required to find the natural number answering to the logarithm 5.5648815.

The next less and greater logarithms, in the table, are

$$\left. \begin{matrix} 5.5647844 \\ 5.5649027 \end{matrix} \right\} \begin{matrix} \text{The number} \\ \text{answering} \end{matrix} \left\{ \begin{matrix} 367100 \\ 367200 \end{matrix} \right.$$

$$\text{Their diff. } .0001183 \qquad\qquad 100$$

And 5,5649027 — 5.5648815 = 0000212.

Therefore .0001183 : 100 : : .0000212 : 18 nearly.

Whence 367200 — 18 = 377182 = number required.

The Use and Application of Logarithms.—It is evident, from what has been said of the construction of logarithms, that addition of logarithms, must be the same thing as multiplication in common arithmetic; and subtraction in logarithms the same as division; therefore, in multiplication by logarithms, add the logarithms of the multiplicand and multiplier together, their sum is the logarithm of the product.

		num.	logarithms.
Example.	Multiplicand	8.5	0.9294189
	Multiplier	10	1.0000000
	Product -	85	1.9294189

And in division, subtract the logarithm of the divisor from the logarithm of the dividend, the remainder is the logarithm of the quotient.

		num.	logarithms.
Example.	Dividend	9712.8	3.9873444
	Divisor	456	2.6589648
	Quotient	21.3	1.3283796

To find the Complement of a Logarithm.—Begin at the left hand, and write down what each figure wants of 9, only what the last significant figure wants of 10; so the complement of the logarithm of 456, viz. 2,6589648, is 7.3410352.

In the Rule of Three. Add the logarithms of the second and third terms together, and from the sum subtract the logarithm of the first, the remainder is the logarithm of the fourth. Or, instead of subtracting a logarithm, add its complement, and the result will be the same.

To raise Powers by Logarithms.—Multiply the logarithm of the number given, by the index of the power required, the product will be the logarithm of the power sought.

Example. Let the cube of 32 be required by logarithms. The logarithm of 32 = 1.5051500, which multiplied by 3, is 4.5154500, the logarithm of 32768, the cube of 32. But in raising powers, viz. squaring, cubing, &c. of any decimal fraction by logarithms, it must be observed, that the first significant figure of the power be put so many places below the place of units, as the index of its logarithm wants of 10, 100, &c. multiplied by the index of the power.

To extract the Roots of Powers by Logarithms.—Divide the logarithm of the number by the index of the power, the quotient is the logarithm of the root sought.

To find Mean Proportionals between any two numbers.—Subtract the logarithm of the least term from the logarithm of the greatest, and divide the remainder by a number more by one than the number of means desired; then add the quotient to the logarithm of the least term (or subtract it from the logarithm of the greatest) continually, and it will give the logarithms of all the mean proportionals required.

Example. Let three mean proportionals be sought, between 106 and 100.

Logarithm of 106=2.0253059
Logarithm of 100=2.0000000

Divide by 4)0.0253059 (0.0063264.75

Log. of the least term	100 added	2.0000000
Log. of the 1st mean	101.4673846	2.0063264.75
Log. of the 2d mean	102.9563014	2.0126529.5
Log. of the 3d mean	104.4670483	2.0189794.25
Log. of the greatest term	106,	2.0253059

It may be of service to the reader here to observe, that one of the most valuable works on this subject, and which is justly held in high repute, as well for its accuracy as for the extent of information it contains, is Dr. Hutton's Mathematical Tables.

LOGIC. Logic is the science which professes to teach the proper application of the mental faculties in all deductions of reasoning. Those, therefore, who have treated expressly of this subject, have endeavoured first, to define and describe the several faculties and operations of the human mind, as perception, judgment, memory, invention, &c. They next proceed to lay down rules for correct reasoning and argument. Every act of the judgment they term a *proposition*, and all propositions are either affirmative or negative. All questions or arguments they reduce to syllogisms, that is from two axioms or propositions (called *terms*, in the technical language) laid down, they reduce a third or conclusion, and the previous propositions they divide into major and minor. Thus, let the question be, *Whether God is an intelligent being?* Here the major or principal proposition proceeds from the word intelligent, and the minor respects God. They would then arrange the syllogism as follows:

Maj. To dispose things in right and perfect order, is the work of an intelligent Being:

Min. But God has disposed creation in right and perfect order;

Conclusion. Therefore, God is an intelligent Being.

They next class or arrange the different kinds of syllogisms according to the nature of them. Propositions are not only affirmative and negative, but they are also particular or universal. Hence syllogisms will vary not only as the major or minor proposition is negative or affirmative, but as either is a universal or particular affirmative, &c.

Mood and figure are words applied by logical writers to denote the arrangement of the terms of a syllogism. It is done by the use of the letters A, E, I, O, of which A denotes universal affirmative; E, universal negative; I, particular affirmative; and O, particular negative. But as it would be difficult to retain in the memory the various changes in the order of these letters, if prefixed to the three parts of a syllogism, fourteen artificial words have been formed, of three syllables each, containing the vowels so to be prefixed in the order of the mood to be denoted by each word. The fourteen moods are classed under these different figures, by which terms logicians mean to denote the particular situation of the middle term, with respect to the major and minor. The first figure is distinguished by the middle term being the subject of the major, and predicate of the minor proposition, and its four moods are denoted by the words *Barbara*, *Celarent*, *Darii*, *Ferio*. The second figure admits of negative conclusions only, the major being always universal, and one of the premises negative. Its moods are *Cesare*, *Camestres*, *Festino*, *Baroco*. And in the third figure the middle term is the subject of both premises, the minor affirmative, and the conclusion, particular. Its moods are *Darapti*, *Felapton*, *Disamis*, *Datisi*, *Bocardo*, *Ferison*.

The following are some of the terms in most common use in logic.

Method is analytical or synthetical. *Analytical method* resolves the compound into its principles, and the whole into its parts. *Synthetical method* begins with the parts, and leads to a whole, or it puts together the principles and forms a compound.

Argumentum at judicium, an appeal to the common sense of mankind;—*ad fidem*, to their faith;—*ad hominem*, to the practices or professed principles of the adversary;—*ad populum*, an appeal to the people;—*ex concesso*, when something is proved by means of some proposition previously conceded;—*ad passiones*, an appeal to the passions.

Certainty or Truth is of several kinds; there is a *mathematical certainty*, which admits of demonstration; a *moral certainty*, which is derived from testimony; a *physical certainty*, derived from the evidence of the senses and the course of nature; and a *theological certainty*, founded on the doctrine of the Scriptures.

Evidence is of different kinds; as the *evidence of sense*, founded on the perceptions of our senses; *the evidence of intuition*, on self-evident axioms, as, that the whole is greater than a part, or, every effect is produced by some cause; *the evidence of reason*, founded on clear and indubitable deductions from well-founded premises and doctrines; and *the evidence of faith*, deduced from the testimony of others.

Demonstrations;—*à priori*, is, when the effect is proved by referring to the cause;—*à posteriori*, is when the cause is inferred from the effects.

Sophistry is reasoning founded on false premises, or an ambiguity of terms. *A Sophism of composition* is when we infer that of any thing in an aggregate or compounded sense, which is only true in a divided sense. *A Sophism of division* is when we infer any thing in a divided sense which is only true in a compounded sense. *A Sophism of equivocation* is when we use words of an ambiguous or double

sense, and draw inferences in one sense, of which the proposition is capable only in the other.

Petitio principii, or begging the question, is the supposition of what is not granted, or a supposed proof, by stating the question in other words. *The Reductio ad absurdum* is when the truth of a proposition is proved by showing the absurdity of a contrary supposition.

A false induction is when general deductions are made from a limited number of experiments or facts. *The fallacia accidentis* is when we draw inferences in regard to the nature of a thing, from circumstances only temporary or accidental. *The Ignorantia elenchi* is a mistake of the question, or when one thing is proved instead of another.

LOGISTICA *numeralis*, the same with algorithm. See ALGORITHM.

LOGISTICAL *arithmetic*, the doctrine of sexagesimal fractions. See SEXAGESIMALS.

LOGOGRAPHY, a method of printing, in which the types, instead of answering only to a single letter, are made to correspond to whole words. The properties of the logographic art are, 1. That the compositor shall have less charged upon his memory, than in the common way. 2. It is much less liable to error. 3. The type of each word is as easily laid hold of as that of a single letter. 4. The decomposition is much more readily performed. 5. No extraordinary expense, nor greater number of types, is required in the logographic, than in the common method of printing.

LOGWOOD, an article well known in the arts, but chiefly used by dyers. The tree which produces it is called by Linnæus, hæmatoxylum Campechianum.

Logwood is so heavy as to sink in water, hard, compact of a fine grain, capable of being polished, and scarcely susceptible of decay. predominant colour is red, tinged with orange, yellow, and black. It yields its colour both to spirituous and watery menstrua. Alcohol extracts it more readily and copiously than water. The colour of its dye is a fine red, inclining a little to violet or purple, which is principally observable in its watery decoction. This, left to itself, becomes in time yellowish, and at length black. Acids turn it yellow; alkalis deepen its colour, and give it a purple or violet hue. See DYEING.

LOLIUM, in botany, *ray grass*, a genus of the triandria digynia class and order, natural order of gramineæ, or grasses. Essential character: calyx one-leafed, fixed, many-flowered. There are five species.

LOMENTACEÆ, in botany, the name of the thirty-third order in Linnæus's Fragments of a natural method, consisting of plants, many of which furnish beautiful dyes, and the pericarpium of which, universally a leguminous pod, contains seeds that are farinaceous or meally like those of the bean. The cassia, wild senna; hæmatoxylon, logwood; mimosa, sensitive plant, &c. are of this order.

LONCHITIS, *spleenwort* a genus of the cryptogamia filices class of plants, the fructifications of which are arranged into lunulated series, and disposed separately under the sinuses of the leaves. There are five species. The leaves of this plant are of use in healing wounds, and in preventing inflammations of them: they are also used against the spleen. The root is aperient and diuretic.

LONGEVITY, may be defined—the continuance of life beyond the ordinary period of duration. The desire of self-preservation is one of the first principles of our nature, and has been implanted in us for the wisest purposes.

While it excites to labour and exertion in procuring the means of supporting our mortal existence, it reconciles us to bear with patience, many distresses and pains, which are in some measure the lot of all. It would be a difficult task to attempt to form a particular set of directions which would be applicable to the various constitutions and employments of mankind. But there are general rules, which all may follow with safety and advantage; and the advice of the celebrated Galen will be found adapted to every situation in which man can be placed.

"Consult your reason," says he, "and observe what agrees and what does not agree with you, that, like wise men, you may adhere to the use of such things as conduce to your health, and forbear every thing which, by your own experience, you find to do you hurt; and be assured, that by a diligent observation and practice of this rule, you may enjoy a good share of health, and seldom stand in need of physic or physicians."

LONGIMETRY, the art of measuring lengths, both accessible, as roads, &c. and inaccessible, as arms of the sea, &c. See SURVEYING.

LONGITUDE *of a star*, in astronomy, an arch of the ecliptic, intercepted between the beginning of Aries and the point of the ecliptic cut by the star's circle of longitude. See CIRCLE, &c.

LONGITUDE *of a place*, in geography, is an arch of the equator intercepted between the first meridian, and the meridian passing through the proposed place; which is always equal to the angle at the pole, formed by the first meridian and the meridian of the place.

LONGITUDE, in navigation, the distance of a ship or place, east or west, from another, reckoned in degrees of the equator.

To find the longitude by a Time-Keeper. The sun appears to move round the earth from east to west, or to describe 360°, in 24 hours, and therefore he appears to move 15° in an hour. If therefore the meridians of two places make an angle of 15° with each other, or if the two places differ 15° in longitude, the sun will come to the eastern meridian one hour before he comes to the western meridian, and therefore when it is twelve o'clock at the former place, it is only eleven at the latter; and in general, the difference between the times by the clock at any two places, will be the difference of their longitudes, converted into time at the rate of 15° for an hour, the time at the eastern place being the forwardest. If, therefore, we can tell what o'clock it is at any two places at the same instant of time, we can find the difference of their longitudes, by allowing 15° for every hour that the clocks differ.

Let, therefore, the timekeeper be well regulated and set to the time at Greenwich, that being the place from which we reckon our longitude; then if the watch neither gains nor loses, it will always show the time at Greenwich, wherever you may be.

LONGITUDINAL, in general, denotes something placed lengthwise: thus some of the fibres of the vessels in the human body are placed longitudinally, others transversely, or across.

LONICERA, *honeysuckle*, a genus of the monogynia order, in the pentandria class of plants. The corolla is monopetalous and irregular; the berry polyspermous, bilocular, and inferior. There are 19 species, of which the most remarkable are, L. grata, ever-green honey-suckle, is the most beautiful: it grows naturally in North America: it has strong branches, covered with a purple bark, which are ornamented with lucid green leaves, embracing the stalks, and continuing their verdure all the year; the flowers are produced in whorled bunches at the end of the branches; there are frequently two, and sometimes three, of these bunches rising one out of the other; they are of a bright red on their outside, and yellow within, of a strong aromatic flavour; it begins to flower in June, and there is a constant succession of flowers till the frost puts an end to them.

LOOF, in the sea-language, is a term used in various senses; thus the loof of a ship is that part of her aloft which lies just before the chest-tree; hence the guns which lie there are called loof-pieces: keep your loof, signifies, keep the ship near to the wind; to loof into a harbour, is to sail into it close by the wind; loof up, is to keep nearer the wind; to spring the loof, is when a ship that was going large before the wind, is brought close by the wind.

LOOKING-GLASSES, are nothing but plane mirrors of glass; which being impervious to the light, reflect the images of things placed before them.

LOOM, a frame composed of a variety of parts, used in all the branches of weaving; for a particular description of which see WEAVING.

LOOM, in the sea-language: when a ship appears big, when seen at a distance, they say she looms.

LOOP, in the iron works, denotes a part of a sow, or block of cast iron, broken or melted off from the rest.

LOOP *holes*, in a ship, are holes made in the coamings of the hatches of a ship, and in their bulk-heads, to fire muskets through, in a close fight.

LOPHIUS, *fishing-frog*, *toad-fish*, or *sea-devil*, a genus of the branchiostegious order of fishes, whose head is in size equal to all the rest of the body. There are three species, the most remarkable of which is the piscatorius, or common fishing-frog, an inhabitant of the British seas. This singular fish grows to a large size, some being between four and five feet in length; and Mr. Pennant mentions one taken near Scarborough, whose mouth was a yard wide. The fishermen on that coast have a great regard for this fish, from a supposition that it is a great enemy to the dog-fish; and whenever they take it with their lines, set it at liberty.

LORD. See PEER.

LORD'S DAY. All persons not having a reasonable excuse, shall resort to their parish church or chapel (or some congregation of religious worship allowed by the toleration act) on every Sunday, on pain of punishment by the censures of the church, and of forfeiting 1s to the poor for every offence; to be levied by the churchwardens by distress, by warrant of one justice. The hundred shall not be answerable for any robbery committed on the Lord's day. No carrier shall travel, or drover drive cattle on the Lord's day, under the penalty of 20*l*. No person upon the Lord's day shall serve or execute any writ, process, warrant, order, judgment, or decree (except in cases of treason, felony, or breach of the peace), but the service thereof shall be void. These, like many other laws in the English code, are now entirely disused, or only enforced on a solitary individual now and then, to gratify personal malice.

LOTTERY, a game of hazard, in which small sums are adventured for the chance of obtaining a larger value, either in money or other articles. Lotteries are formed on various plans; but in general they consist of a certain number of tickets, which are drawn at the same time, with a corresponding number of blanks and prizes mixed together, and by which the fate of the tickets is determined.

This species of gaming has been sanctioned by the governments of France, Holland, Great Britain, and other countries, as a means of raising money for public purposes; as from the contributions being voluntary, it is always easier to obtain money in this way than by new taxes; it is, however liable to the serious objection, that it tempts many persons to lose more than they can conveniently spare, particularly among the lower classes of society, who are led to neglect the gains of honest industry for the chance of acquiring sudden riches by a prize in the lottery.

LOUIS, or KNIGHTS OF ST. LOUIS, the name of a military order in France, instituted by Louis XIV. in 1693.

LOUSE. See PEDICULUS.

LOXIA, a genus of birds of the order of passeres, the distinguishing characters of which are: the bill is strong, convex above and below, and very thick at the base; the nostrils are small and round; the tongue is as if cut off at the end; the toes are four, placed three before and one behind, excepting one species, which has only two toes before and one behind. The most remarkable are:

1. The *curvirostra*, or common cross-bill, is about the size of a lark, is known by the singularity of its bill, both mandibles of which curve opposite ways and cross each other: the general colour of the plumage in the male is of a red-lead, inclining to rose-colour; the wings and tail are brown; the legs black. The female is of a green colour, mixed with brown in those parts where the male is red. It is found in North America and Greenland; and is said to make its nest in the highest parts of the fir trees, fastening it to the branch with the resinous matter which exudes from the trees.

2. The *coccothraustes*, or haw-finch, is in length seven inches. This species is ranked among the British birds; but only visits these kingdoms occasionally, and for the most part in winter, and is never known to breed here. It is more plentiful in France. It feeds on berries, kernels, &c.

3. The *pyrrhula*, or bullfinch, is so generally known as almost to supersede description. This species is common in most parts of the continent of Europe, and throughout Russia and Siberia,

at which last places it is caught for the table. In winter it approaches gardens and orchards, and has been generally stigmatised for making havock among the buds of trees. The bullfinch in its wild state, has only a plain note; but when tamed, it becomes remarkably docile, and may be taught any tune after a pipe, or to whistle any notes in the best manner: it seldom forgets what it has learned; and will become so tame as to come at call, perch on its master's shoulders, and (at command) go through a difficult musical lesson. They may be also taught to speak, and some thus instructed are annually brought to London from Germany.

4. The *cardinalis*, or cardinal grossbeak, is near eight inches in length. The bill is stout, and of a pale-red colour; the irides are hazel; the head is greatly crested, the feathers rising up to a point when erect; round the bill, and on the throat, the colour is black: the rest of the bird of a fire-red. This species is met with in several parts of North America, and has attained the name of Virginia nightingale, from the fineness of its song, the note of which resembles that of the nightingale.

5. The *orix*, or grenadier grossbeak, is about the size of a house-sparrow. The forehead, sides of the head, and chin are black; the breast and belly the same; the wings are brown, with pale edges; and the rest of the body of a beautiful red colour. These birds are inhabitants of St. Helena; they are also in plenty at the Cape of Good Hope, where they frequent watery places that abound with reeds, and among which they are supposed to make their nest.

LOZENGE, **Lozange**, *rhombus*, in geometry, a quadrilateral figure, consisting of four equal and parallel sides, two of whose opposite angles are acute and the other two obtuse; the distance between the two obtuse ones being always equal to the length of one side.

Lozenge, in pharmacy, the same with what is otherwise called troche.

LUCANUS, *stag-chaffer*, a genus of insects of the order coleoptera; the generic character is, antennæ clavated, with compressed tip, divided into lamellæ on the inner side; jaws stretched forwards, exserted, and toothed. The principal species is the lucanus cervus, commonly known by the name of the stag-beetle, or stag-chafier. It is the largest of all the European coleopterous insects, sometimes measuring nearly two inches and a half in length, from the tips of the jaws to the end of the body. Its general colour is a deep chesnut, with the thorax and head, which is of a squarish form, of a blacker cast: and the jaws are often of a brighter or redder chesnut colour than the wing-shells; the legs and under parts are coal-black, and the wings, which, except during flight, are concealed under the shells, are large and of a fine pale yellowish brown. This remarkable insect is chiefly found in the neighbourhood of oak-trees, delighting in the sweet exsudation or honey-dew so frequently observed on the leaves.

LUCERNE, is a plant frequently cultivated in the manner of clover. Its leaves, like the latter, grow three at a joint, its stalks are erect, and after mowing, immediately spring up again from the stubble. It is made into hay, in the same manner as saintfoin, but should be mowed before it flowers. It makes the sweetest and most fattening food in the world for cattle.

LUCIDA, in astronomy, an appellation given to several fixed stars on account of their very superior brightness; as the lucida coronæ, a star of the second magnitude in the northern crown.

LUDWIGIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. There are four species, annuals of the West Indies.

LUES, among physicians is, in general, used for a disease of any kind; but in a more particular sense, is restrained to contagious and pestilential diseases, as the lues venerea.

LUMBAGO, in medicine, a rheumatic affection of the muscles about the loins.

LUNA, in astronomy, the moon. See Moon.

LUNAR, something belonging to the moon: thus we say lunar month, lunar year, lunar dial, lunar eclipse, &c.

Lunar *caustic*, is the old name for nitrate of silver, a very powerful caustic, much used in medicine. It is also called "lapis infernalis," by surgeons.

LUNATIC. See Idiot.

LUNATION, the period or time between one new moon and another: it is also called the synodical month, consisting of 29d. 12h. 44′ 3″ 11-3ds; exceeding the periodical month by 2d. 5h. 0′ 55.″

LUNE, in mathematics, is a geometrical figure, in form of a crescent, terminated by the arcs of two circles that intersect each other within.

LUNGS. See Anatomy, and Physiology.

LUPINUS, *lupin*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. There are ten species, chiefly hardy herbaceous flowery annuals, rising with upright stalks from one to three or four feet high, ornamented with digitate or fingered leaves, and terminated by long whorled spikes of papilionaceous flowers, white, blue, yellow, and rose-coloured.

LUPUS, in astronomy, a southern constellation, consisting of 19, or, according to Flamsteed, of 24 stars.

LUST, in the sea-language. When a ship heels more one way than another, she is said to have a lust that way

LUSTRE, in mineralogy, is a term much used in modern works of chemistry. The lustre of minerals in respect of intensity, is of five kinds; 1. Splendent, when in full day-light the lustre can be seen at a great distance. 2. Shining, when at a distance the reflected light is weak: 3. Glistening, when the lustre is only observable at no greater distance than an arm's length. 4. Glimmering, when the surface held near the eye in full day-light presents a number of shining points: 5 Dull, when the surface

has no lustre. There are two kinds of lustre, the metallic and common. See THOMPSON'S CHEMISTRY.

LUTE, a stringed instrument formerly much in use; anciently containing only five rows of strings, but to which six, or more, were afterwards added. The lute consists of four parts, viz. the table, the body which has nine or ten sides; the neck, which has as many stops or divisions; and the head, or cross, in which screws for turning it are inserted. In playing this instrument, the performer strikes the strings with the fingers of the right hand, and regulates the sounds with those of the left hand.

LUTE. The lutes with which the joinings of vessels are closed, are of different kinds, according to the nature of the operations to be made, and of the substances to be distilled in these vessels. When vapours of watery liquors, and such as are not corrosive, are to be contained, it is sufficient to surround the joining of the receiver to the nose of the alembic, or of the retort, with slips of paper or of linen, covered with flour-paste. In such cases also slips of wet bladder are very conveniently used.

When more penetrating and dissolving vapours are to be contained, a lute is to be employed of quicklime slacked in the air, and beaten into a liquid paste with whites of eggs. This paste is to be spread upon linen slips, which are to be applied exactly to the joining of the vessels. This lute is very convenient, easily dries, becomes solid, and sufficiently firm. Of this lute, vessels may be formed hard enough to bear polishing on the wheel. Lastly, when acid and corrosive vapours are to be contained, we must then have recourse to the lute called *fat lute*. This lute is made by forming into a paste some dried clay finely powdered, sifted through a silken searce, and moistened with water, and then by beating this paste well in a mortar with boiled linseed oil, that is, oil which has been rendered drying by litharge dissolved in it, and fit for the use of painters. This lute easily takes and retains the form given to it. It is generally rolled into cylinders of a convenient size. These are to be applied, by flattening them to the joinings of the vessels, which ought to be perfectly dry, because the least moisture would prevent the lute from adhering. When the joinings are well closed with this fat lute, the whole is to be covered with slips of linen spread with lute of lime, and whites of eggs. These slips are to be fastened with packthread. The second lute is necessary to keep on the flat lute, because this latter remains soft, and does not become solid enough to stick on alone. Fine porcelain clay, mixed with a solution of borax, is well adapted to iron vessels, the part received into an aperture being smeared with it.

LYCOPODIUM. The fine dust of lycopodium, or clubmoss, is properly the seeds of the plant, and when diffused or strewed in the air, it takes fire from a candle, and burns off like a flash of lightning. It is used in the London theatres.

LYDIAN *stone*, in mineralogy, is of a greyish black colour, which passes into velvet black; it occurs massive, and is likewise found in trapezoidal-shaped rolled pieces, with rounded angles; it is hard, but not very heavy. This mineral is found near Prague and Carlsbad, in Bohemia; in other parts of Germany, and in Scotland. When polished it is used as a test stone for determining the purity of gold and silver; owing, however, to its great hardness, it is less suited for this purpose than basalt. It takes its name from the circumstance of its being first found in the province of Lydia, in Lesser Asia.

LYING *to*, in naval affairs, the situation of a ship when she is retarded in her course, by arranging the sails in such a manner as to counteract each other with nearly equal effort, and render the ship almost stationary with respect to her head-way; a ship is usually brought to by laying down her main-top-sail aback the helm being put close down to leeward. This is particularly practised in a general engagement, when the hostile fleets are drawn up in two lines of battle opposite each other.

LYMPH. See ANATOMY, and PHYSIOLOGY.

LYNX. See FELIS.

LYRE, *lyra*, in astronomy, a constellation of the northern hemisphere, the number of whose stars, in Ptolemy and Tycho's catalogues, are only ten, but nineteen in the Britannic catalogue.

LYRE *lyra*, a musical instrument of the string kind, much used by the ancients.

LYRIC. See POETRY.

LYSIMACHIA, *loosestrife*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. There are 12 species, but only four are commonly cultivated in gardens. These are hardy herbaceous perennials and biennials, rising with erect stalks from 18 inches to two or three feet high, and terminated by spikes and clusters of monopetalous, rotated, five-parted spreading flowers of white and yellow colours.

LYTHRUM, *purple loosestrife*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. There are 18 species, of which the most remarkable is, the cilicari, or common purple loosestrife, with oblong leaves, is a native of Britain, and grows naturally by the sides of ditches and rivers.

M.

M, the twelfth letter of our alphabet. As a numeral it stands for mille a thousand; and with a dash over it, thus M, for a thousand times a thousand, or 1,000,000. M. A. magister artium; MS. manuscript, and MSS. manuscripts. In the prescriptions of physicians, M. stands for manipulus, a handful; and sometimes for misce, or mixtura.

MABA, a genus of the triandria order, in the diœcia class of plants. There is one species, a tree of the Friendly Islands.

MABEA, a genus of the monoecia polyandria class and order. The calyx is one-leaved; corolla none. There are two species, called pipewood, shrubs of the West Indies.

MACARONIC, or *macaronian*, an appellation given to a burlesque kind of poetry, made up of a jumble of words of different languages, and words of the vulgar tongue latinized. The Italians are said to have been the inventors of it. The Germans, French, Spaniards, &c. have also had their macaronic poets; nor is Great Britain outdone in this respect, as appears from a poem by Drummond of Hawthornden, called Polemo Middinia, and which begins thus,

> Nymphæ, quæ colitis bighissima monta Fifæa,
> Seu vos Pittenweema tenet, seu Crelia crofta,
> &c.

MACE, the second coat of the kernel of the nutmeg, is a thin and membranaceous substance, of an oleaginous nature, and a yellowish colour, being met with in flakes of an inch or more in length, which are divided into a multitude of ramifications. It is of an extremely fragrant, aromatic and agreeable flavour, and of a pleasant, but acrid and oleaginous taste. See MYRISTICA

MACERATION, in pharmacy, is an infusion of, or soaking ingredients in, water or any other fluid, in order either to soften them, or draw out their virtues.

MACHINE. See MECHANICS.

MACHINERY, in epic and dramatic poetry, is when the poet introduces the use of machines, or brings some supernatural being upon the stage, in order to solve some difficulty, or to perform some exploit out of the reach of human power. The ancient dramatic poets never made use of machines, unless where there was an absolute necessity for so doing; whence the precept of Horace,

> "Nec Deus intersit, nisi dignus vindice
> nodus—inciderit."

MACKREL. See SCOMBER.

MACROCNEMON, a genus of the class and order pentandria monogynia. The cor. is bell-shaped; the capsule two-celled, two-valved; seeds imbricate. There are three species, small trees of the West Indies.

MACROPUS, the *kanguroo*, in natural history, a genus of mammalia of the order Feræ. Generic character: six front teeth in the upper jaw, emarginated; two in the lower, and very long, sharp, large, and pointing forwards; five grinders on each side of the upper and under jaw, distant from the other teeth; fore-legs very short; hind ones very long; the female with an abdominal pouch. This is one of the most curious of all the animals discovered on the continent of New South Wales, where it was observed by some of the sailors of Captain Cook in the year 1770. When full grown it weighs about 150 pounds. Its head somewhat resembles that of a deer, but is destitute of horns; its colour is of a pale brown; its length from the nose to the tail is between four and five feet, and the length of the tail is about three feet. Its general position, when resting, is that of standing on its hind feet, on their whole extent to the knees, and its fore-feet are frequently employed, like those of the squirrel, as hands. They are often, however, laid on the ground, and the kanguroo is often seen in this posture, feeding. Vegetables, and particularly grass, constitute its only nourishment. In its rapid motions, however, the fore-feet are wholly useless, and it proceeds by leaping on its hind feet, which it will do to the distance of fourteen or sixteen feet, and with bounds so rapid in succession, that it exceeds in swiftness a common dog. Kanguroos possess the faculty of separating at pleasure the two front teeth of their lower jaw; and the female is furnished with a pouch in the abdomen, of extraordinary depth, in which are placed two teats. But one young one is produced at a time, which, when first observed in the pouch, after its birth, is scarcely more than an inch in length, but grows to a considerable size in this natural receptacle before it quits it, and frequently recurs to it for warmth and security after its first dislodgment from it. This animal is in this striking circumstance allied to the opossum genus, under which Gmelin ranks it; but it differs from the opossum materially in respect to the structure of the teeth.

MACULÆ, in astronomy, are dark spots appearing on the luminous surfaces of the sun and moon, and even some of the planets. The solar maculæ are dark spots of an irregular and changeable figure, observed in the face of the sun. These were first observed in November and December of the year 1610, by Galileo in Italy, and Harriot in England, unknown to, and independent of, each other, soon after they had made or procured telescopes.

There have been various observations made of the phenomena of the solar maculæ, and hypothesis invented for explaining them.

Many of these maculæ appear to consist of heterogenous parts; the darker and denser being called, by Hevelius, nuclei, which are encompassed, as it were, with atmospheres, somewhat rarer and less obscure; but the figure, both of the nuclei and entire maculæ, is variable. These maculæ are often subject to sudden mutations.

The spots, or maculæ, observable on the moon's surface, seem to be only cavities or large caverns, on which the sun shining very obliquely, and touching only their upper edge with his light, the deeper places remain without light; but as the sun rises higher upon them

they receive more light, and the shadow, or dark parts, grow smaller and shorter, till the sun comes at last to shine directly upon them, and then the whole cavity will be illuminated: but the dark dusky spots, which continue always the same, are supposed to proceed from a kind of matter or soil which reflects less light than that of the other regions.

MADDER, a substance very extensively employed in dyeing, is the root of the rubia tinctorum. Although madder will grow both in a stiff clayey soil and in sand, it succeeds better in a moderately rich, soft, and somewhat sandy soil: it is cultivated in many of the provinces of France, in Alsace, Normandy, and Provence: the best of European growth is that which comes from Zealand. The best roots are about the thickness of a goose quill, or at most of the little finger; they are semitransparent, and of a reddish colour: they have a strong smell, and the bark is smooth. Hellot ascribes the superiority of the madder which comes from the Levant to the circumstance of its having been dried in the open air. The red colouring matter of madder may be dissolved in alcohol, and on evaporation a residium of a deep red is left. Fixed alkali forms in this solution a violet, the sulphuric acid a fawn coloured, and the sulphate of potash, a fine red precipitate. Precipitate of various shades may be obtained by alum, nitre, chalk, sugar of lead, and the muriate of tin. The quantity of aqueous chlorine required to destroy the colour of a decoction of madder, is double what is necessary to destroy that of a decoction of an equal weight of Brasil wood.

Wool would receive from madder only a perishable dye, if the colouring particles were not fixed by a base, which occasions them to combine with the stuff more intimately, and which in some measure defends them from the destructive influence of the air. For this purpose, the woollen stuffs are first boiled for two or three hours with alum and tartar, after which they are left to drain; they are then slightly wrung and put into a linen bag, and carried into a cool place, where they are suffered to remain for some days.

The madder red of cotton is distinguished into two kinds: one is called simple madder red; the other, which is much brighter, is called Turkey or Adrianople red, because it comes from the Levant, and has seldom been equalled in brightness or durability by our artists. Galls or sumach dispose thread and cotton to receive the madder colour, and the proper mordant is acetate of alumina. The nitrate and muriate of iron as a mordant produces a better effect than the sulphate and acetate of the same metal; they afford a beautiful, well saturated violet colour.

MADREPORA, in natural history, the name of a genus of submarine substances, the characters of which are, that they are almost of a stony hardness, resembling the corals, and are usually divided into branches, and pervious by many holes or cavities, which are frequently of a stellar figure. In the Linnæan system, this is a genus of lithophyta; the animal that inhabits it is a medusa; it comprehends about 120 species.

MADREPORITE, a mineral found in the valley of Russback, in Salzburg, and so called from its external resemblance to madrepore. It is found in large masses, is brittle and moderately heavy. Its component parts are,

Carbonate of lime	93.00
Carbonate of magnesia	0.50
Carbonate of iron	2.25
Charcoal	0.50
Silica	4.50
	99,75
Loss	25
	100

MADRIER, in the military art, a long and broad plank of wood, used for supporting the earth in mining and carrying on a sap, and in making coffers, caponiers, galleries, and for many other uses at a siege.

MADRIGAL, in the Italian, Spanish, and French poetry, is a short amorous poem, composed of a number of free and unequal verses, neither confined to the regularity of a sonnet, nor to the point of an epigram, but only consisting of some tender or delicate thought, expressed with a beautiful, noble, and elegant simplicity.

MAGAZINE, a place in which stores are kept, or arms, ammunition, provisions, &c. Every fortified town ought to be furnished with a large magazine, which should contain stores of all kinds, sufficient to enable the garrison and inhabitants to hold out a long siege.

Magazine, *powder*, is that place where the powder is kept in very large quantities. Authors differ greatly both in regard to situation and construction; but all agree, that they ought to be arched, and bomb-proof.

MAGI, or Magians, an ancient religious sect in Persia, and other Eastern countries, who maintained, that there were two principles, the one the cause of all good, the other the cause of all evil; and abominating the adoration of images, worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Oromasdes, or the good God: as darkness is the truest symbol of Arimanius, or the evil God. This religion was reformed by Zoroaster. The sect still subsists in Persia, under the denomination of gaurs.

MAGIC, originally signified only the knowledge of the more sublime parts of philosophy; but as the magi likewise professed astrology, divination, and sorcery, the term magi became odious, being used to signify an unlawful diabolical kind of science, acquired by the assistance of the devil and departed souls.

Natural magic is only the application of natural philosophy to the production of surprising but yet natural effects. The common natural magic, found in books, gives us merely some childish and superstitious traditions of the sympathies and antipathies of things, or of their occult and peculiar properties; which are usually intermixed with many trifling experiments, admired rather for their disguise than for themselves.

MAGIC *lantern*. See Optics.

Magic *square*, in arithmetic, a square figure made up of numbers, so disposed in parallel and equal ranks, that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal.

The following diagram represents one of these squares; but the subject is not deserving of any serious attention.

16	14	8	2	25
3	22	20	11	9
15	6	4	23	17
24	18	12	10	1
7	5	21	19	13

MAGNA *Charta*, the great charter of liberties, granted in 1215, the 16th year of king John, and confirmed by Edward I. The reason of its being termed *magna*, or *great*, is, either because of the excellency of the laws and liberties therein contained; or because there was another charter, called *charta de foresta*, established with it, which was the less of the two; or because it contained more than other charters; or on account of the wars and troubles in the obtaining it, or of the great and remarkable solemnity in the denouncing excommunications against the infringers of it. Magna Charta may be said to derive its origin from king Edward the Confessor, who granted several liberties and privileges, both civil and ecclesiastical, by charter; the same, with some others, were also granted and confirmed by king Henry I, by a celebrated great charter, now lost. And his successors, king Stephen, king Henry II, and finally, king John, confirmed or re-enacted the same; but this last prince violating his charter, the barons took up arms, and his reign ended in blood.—Henry III, who succeeded him, after having procured an inquisition to be made by twelve men in each county, what the liberties of England were in the time of Henry I, renewed the great charter granted by John, which he several times confirmed, and as often broke again; till in the 37th year of his reign he came to Westminster-hall, where, in the presence of the nobility and bishops, with lighted candles in their hands, Magna Charta was read, the king all the while laying his hand on his breast, and at last solemnly swearing, faithfully and inviolably to observe all things therein contained, as a man, a Christian, a soldier, and a king. Then the bishops extinguished their candles, throwing them on the ground, crying, 'Thus let him be extinguished and stink in Hell, who violates this charter.' Magna Charta was thought to be so beneficial to the subject, and a law of so great equity in comparison with those which were formerly in use, that king Henry, for restoring it, had the fifteenth penny of all the moveable goods, both temporal and spiritual. Sir Edward Coke observes, Magna Charta has been above thirty times confirmed.

MAGNESIA. One of the primitive earths, having a metallic basis, called magnesium. It has been found native in the state of hydrate.

Magnesia may be obtained, by pouring into a solution of its sulphate, a solution of subcarbonate of soda, washing the precipitate, drying it, and exposing it to a red heat. It is usually procured in commerce, by acting on magnesian limestone with the impure muriate of magnesia, or bittern of the sea-salt manufactories. The muriatic acid goes to the lime, forming a soluble salt, and leaves behind the magnesia of both the bittern and limestone. Or the bittern is decomposed by a crude subcarbonate of ammonia, obtained from the distillation of bones in iron cylinders. Muriate of ammonia and subcarbonate of magnesia result. The former is evaporated to dryness, mixed with chalk and sublimed. Subcarbonate of ammonia is thus recovered, with which a new quantity of bittern may be decomposed; and thus in ceaseless repetition, forming an elegant and economical process:—100 parts of crystallized Epsom salt, require for complete decomposition 56 of subcarbonate of potash, or 44 dry subcarbonate of soda, and yield 16 of pure magnesia after calcination.

Magnesia is a white, soft powder. Its specific gravity is 2.3 by Kirwan. It renders the syrup of violets, and infusion of red cabbage, green, and reddens turmeric. It is infusible, except by the hydroxygen blowpipe. It has scarcely any taste, and no smell. It is nearly insoluble in water; but it absorbs a quantity of that liquid with the production of heat. And when it is thrown down from the sulphate by a caustic alkali, it is combined with water constituting a hydrate, which, however, separates at a red heat. It contains about one-fourth its weight of water.

When magnesia is exposed to the air, it very slowly attracts carbonic acid. It combines with sulphur, forming a sulphuret.

Magnesia is chiefly used as an antacid, purgative, and lithontriptic in medicine. When incautiously used for a long time, it may produce very serious evils.

MAGNESIA *hydrate of*. This mineral was found by Dr. Bruce of New York, in small veins in serpentine at Hoboken, in New Jersey. Colour white. Massive. Lustre pearly. Fracture foliated or radiated. Semitransparent in the mass; transparent in single folia. Soft, and somewhat elastic. Adheres slightly to the tongue. Specific gravity 2.13. Soluble in acids. Its constituents are magnesia 70, water 30, which approaches to 1 prime equivalent of each.

MAGNESIAN *limestone*, or DOLOMITE, a species of marble found in the Alps, and in Icolmkill in Scotland, and also in Nottinghamshire and Derbyshire. Its constituents, according to Mr. Tennant, are,

Magnesia,	20.3 to 20.5.
Lime,	29.5 to 30.7.
Carbonic acid,	47.2.
Clay and oxide of iron,	0.8.

MAGNETISM. The natural magnet, or loadstone, is a hard mineral body of a dark brown, or almost black colour, and when examined, is found to be an ore of iron. It is met with in various countries, generally in iron mines, and of all sizes and forms.

It is not precisely known when and by whom the directive property of the magnet was discovered. The most probable accounts seem to prove, that it was known early in the 13th century; and that the person who first made mariners' compasses, at least in Europe, was a Neapolitan of the name of Flavio, or John de Gioga, or Giova, or Gira.

The natural loadstone has also the quality of communicating its properties to iron and steel; and when pieces of steel properly prepared are touched, as it is called, by the loadstone they are denominated artificial magnets.

These artificial magnets are even capable of being made more powerful than the natural ones; and as they can be made of any form, and are more convenient, they are now universally used, so that the loadstone or natural magnet is only kept as a curiosity.

All magnets, whether natural or artificial, are distinguished from other bodies by the following characteristics.

1. A magnet attracts iron.

2. When a magnet is placed so as to be at liberty to move freely in every direction, its ends point towards the poles of the earth, or very nearly so; and each end always points to the same pole. This is called the polarity of the magnet; the ends of the magnet are called poles; and they are called north and south poles of the magnet, according as they point to the north or south pole of the earth. When a magnet places itself in this direction, it is said to traverse.

3. When the north pole of one magnet is presented to the south of another magnet, these ends attract each other; but if the south pole of one magnet is presented to the south pole of another, or the north pole of one to the north pole of another, these ends will repel each other.

4. When a magnet is situated so as to be at liberty to move itself with sufficient freedom, its two poles do not lie in a horizontal direction, but it generally inclines one of them towards the horizon, and of course it elevates the other pole above it. This is called the inclination or dipping of the magnet.

5. Any magnets may, by proper methods, be made to impart those properties to iron or steel.

A plai perpendicular to the ho, and passing through the poles of a magnet when standing in their natural direction, is called the magnetic meridian; and the angle which the magnetic meridian makes with the meridian of the plane where the magnet stands, is called the declination of the magnet at that place.

Magnetic Attraction and Repulsion.

When a piece of iron is brought within a certain distance of one of the poles of a magnet, it is attracted by it; and if the iron is at liberty to move, it adheres to the magnet, and cannot be separated without some force. It appears at first sight, that the attraction lies only in the magnet, but experiment proves this attraction to be mutual: the iron attracting the magnet as much as the magnet attracts the iron. This attraction is strongest at the poles of a magnet, and diminishes in proportion to the distance of any part from the poles, so that in the middle between the poles there is no attraction. The intensity of the attractive power diminishes also, according to the distance from the magnet.

As magnetic attraction takes place only between poles of different names of different magnets; consequently magnetic repulsion acts only between poles of the same name of different magnets. When a piece of iron is brought within a certain distance of a magnet, it becomes, in fact, itself a magnet, having the polarity, the attractive and repulsive properties for other iron, &c. Thus if A B, plate XXVIII, fig. 1, be an oblong piece of iron, and be brought near the north pole N of the magnet N S, this piece of iron while standing within the magnet's sphere of action, will have all the properties of a real magnet, and its end A will be found to be a south pole, while the end B is a north pole. Soft iron, when placed within the influence of a magnet, easily acquires these properties; but they last only while the iron remains in that situation, and when it is removed its magnetism vanishes immediately. But with iron containing carbon, and particularly with steel, the case is very different; and the harder the iron or the steel is, the more permanent is the magnetism which it acquires from the influence of a magnet; but it will be in the same proportion more difficult to render it magnetic. Neither the magnetic attraction nor repulsion is in the least diminished, or at all affected, by the interposition of any sort of bodies, except iron, or such bodies as contain iron.

The properties of the magnet are not affected either by the presence or by the absence of air. Heat weakens the power of a magnet, and subsequent cooling restores it, but not quite to its former degree. A white heat destroys it entirely, or very nearly so; and hence it appears, that the powers of magnets must be varying continually.

The attractive power of a magnet may be considerably improved by suspending a weight of iron to it by its power of attraction, which may be gradually increased; and also by keeping it in a proper situation, viz. with its north pole towards the north, and its south pole, consequently, towards the south. On the contrary, this power is diminished by an improper sit tion, and by keeping too small a piece of iron, or no iron at all, appended to it.

Amongst the natural magnets, the smallest generally possess a greater attractive power in proportion to their size than those of a larger size. It frequently happens that a natural magnet, cut off from a larger loadstone, will be able to lift a greater weight of iron than the original loadstone itself. As both magnetic poles together attract a much greater weight than a single pole; and as the two poles of a magnet generally are in opposite parts of its surface, in which case it is almost impossible to adapt the same piece of iron to them both at the same time; therefore it has be monly practised to adapt two broad pieces of soft iron to the poles of the stone, and to let them project on one side of the stone; for those pieces become themselves magnetic while thus situated, and to them the piece of iron or weight may be easily adapted. Those two pieces of iron are generally fastened upon the stone by means of a brass or silver box. The magnet in this case is said to be armed; and the two pieces of iron are called the armature.

Fig. 2 represents an armed magnet, where A B is the loadstone; C D, CD, are the armature, or the two pieces of soft iron, to the projections of which DD the iron weight F is to be applied. The dots ECDCD represent the brass box, with a ring at E, by which the armed magnet may be suspended.

Of the Polarity of the Magnet.

Every magnet has a south and north pole, which are at opposite ends; and a line drawn from one end to the other, passes through the centre of the magnet. Here it must not be understood, that the polarity of a magnet resides

only in two points of its surface; for in reality, it is the one half of the magnet that is possessed of one kind of polarity; and the other half of the other kind of polarity; the poles, then, are those points in which that power is the strongest.

It is the polarity of the magnet that renders it so useful to navigators. When a magnet is kept suspended freely, so that it may turn north and south, the pilot by looking at the position of it, can steer his course in any required direction. Although the north pole of the magnet in every part of the world, when suspended, points towards the northern parts, and the south pole towards the southern parts, yet its ends seldom point exactly towards the poles of the earth. The angle in which it deviates from due north and south, is called the angle of declination, or the declination of the magnetic needle, or the variation of the compass; and this declination is said to be east or west, according as the north pole of the needle is eastward or westward of the astronomical meridian of the place. This deviation from the meridian is not the same in all parts of the world, but is different in different places, and it is even continually varying in the same place.

The declination from the meridian, and the variation of this in different parts of the world, are very uncertain, and have hitherto formed a great impediment to the improvement of navigation. This however is likely to be in a great measure removed, by the successful experiments of Mr. Barlow, on the local attraction of vessels. When the variation was first observed, the north pole of the magnetic needle declined eastward of the meridian of London; but it has since that time been changing continually towards the west; so that in the year 1657 the magnetic needle pointed due north and south. At present it declines about 24½° westward, but seems to be returning again towards the east. Before volcanic eruptions and earthquakes, the magnetic needle is often subject to very extraordinary movements. It is also agitated before and after the appearance of the aurora borealis; a circumstance which indicates a near affinity between electricity and magnetism.

Inclination or dip of the magnetic Needle.

If a needle which is accurately balanced, and suspended so as to turn freely in a vertical plane, is rendered magnetical, the north pole will be depressed, and the south pole elevated above the horizon; this property is called the inclination, or dip of the needle, and was discovered by Robert Norman, about the year 1576.

Take a globular magnet, or an oblong one, like SN, fig. 4; the extremity N of which is the north pole, the other extremity S is the south pole, and A is its middle or equator; place it horizontally upon a table CD: then take another small oblong magnet *n s*, and suspend it by means of a fine thread tied to its middle, so as to remain in an horizontal position, when not disturbed by the vicinity of iron. Now if the same small magnet, held by the upper part of the thread, be brought just over the middle of the large magnet, within two or three inches of it, the former will turn its south pole *s*, towards the north pole, N. of the large magnet, and its north pole *n*, towards the south pole S of the large one. It will be farther observed, that the small magnet, whilst kept just over the middle A of the large one, will remain parallel to it; but if the small magnet be moved a little nearer to one end than to the other of the large magnet, then one of its poles, namely, that which is nearest to the contrary pole of the large magnet, will be inclined downwards, and of course the other pole will be elevated above the horizon. If the small magnet be brought just opposite to one of the poles of the large magnet, it will turn the contrary pole towards it, and will place itself in the same straight line with the axis of the large magnet.

To communicate the magnetic virtue.

There are various methods of giving the magnetic property to steel or iron. Take a bar of iron three or four feet long, and hold it in a vertical position, you will find that the bar is magnetic. If the bar be inverted, polarity will be instantly reversed: the extremity which is now lowest, will be found to be a north pole, and the other extremity will be a south pole.

Bars of iron that have stood in a perpendicular position, are generally found to be magnetical, as fire-irons, bars of windows, &c. If a long piece of hard iron is made red-hot, and then left to cool in the direction of the magnetical line, it becomes magnetical. Striking an iron bar with a hammer, or rubbing it with a file, while held in this direction, likewise renders it magnetical. An electric shock produces the same effect; and lightning often renders iron magnetic. A magnet cannot communicate a degree of magnetism stronger than that which itself possesses; but two or more magnets, joined together, may communicate a greater power to a piece of steel, than either of them possesses singly.

1. Place two magnetic bars, A, B, fig. 5, in a line with the north end of one, opposed to the south end of the other; but at such a distance from each other, that the magnet to be touched may rest with its north end on the south end of A, and *vice versa*, then apply the north end of the magnet E, and the south end of D, to the middle of the bar C, the opposite ends being elevated as in the figure; draw E and D asunder along the bar C, one towards A, the other towards B, preserving the same elevation; remove E and D a foot or two from the bar when they are off the ends, then bring the north and south poles of these magnets together, and apply them again to the middle of the bar C as before: repeat the same process five or six times, then turn the bar and touch the opposite surface in the same manner, and afterwards the two remaining surfaces; by this means the bar will acquire a strong fixed magnetism.

2. Place the two bars which are to be touched parallel to each other; and then unite the ends by two pieces of soft iron, called supporters, in order to preserve, during the operation, the circulation of the magnetic matter; the bars are to be placed so that the end D, fig. 6, may be opposite the end B; then place the two attracting poles G and I on the middle of one of the bars to be touched, raising the ends, so that the bars may form an obtuse angle of 100 or 120 degrees; the ends G and I of the bars are to

be separated two or three tenths of an inch from each other. Keeping the bars in this position, move them slowly over the bar AB, from one end to the other, going from end to end about fifteen times. Having done this, change the poles of the bars, and repeat the same operation on the bar CD, and then on the opposite faces of the bars. The touch thus communicated may be further increased, by rubbing the different faces of the bars with sets of magnetic bars, disposed as in fig. 7.

It may, perhaps, be necessary to say something concerning the communication of magnetism to crooked bars like ABC, fig. 8. Place the bar flat upon a table, and to its extremities apply the magnetic bars DF, EG; joining their extremities FG, with the conductor or piece of soft iron FG; then to its middle apply the magnetic bars placed at an angle; or you may use two bars only, placed as shewn in fig. 9, and stroke the crooked bar with them from end to end, following the direction of that bent bar; so that on one side of it the bars may stand in the direction of the dotted representation LK. In this manner, when the piece of steel ABC has been rubbed a sufficient number of times on one side, it must be turned with the other side upwards, &c.

The magnetic needles, which are commonly used at sea, are between four and six inches long; but those which are used for observing the daily variation, are made a little longer, and their extremities point the variation upon an arch or circle properly divided and affixed to the box. The best shape of a magnetic needle is represented in figs. 9 and 10; the first of which shews the upper side, and the second shews a lateral view of the needle, which is of steel, having a pretty large hole in the middle, to which a conical piece of agate is adapted by means of a brass piece O, into which the agate-cap is fastened. Then the apex of this hollow cap rests upon the point of a pin F, which is fixed in the centre of the box, and upon which the needle, being properly balanced, turns freely.

A mariner's compass, or compass generally used on board of ships, is represented in fig. 11. The box, which contains the card or fly with the needle, is made of a circular form, and either of wood, or brass, or copper. It is suspended within a square wooden box, by means of two concentric circles, called gimbalds, so fixed by cross axes to the two boxes, that the inner one, or compass-box shall retain a horizontal position in all motions of the ship. The compass-box is covered with a pane of glass, in order that the motion of the card may not be disturbed by the wind. See fig. 12. What is called the card is a circular piece of paper, which is fastened upon the needle, and moves with it. The outer edge of this card is divided into 360 equal parts or degrees, and within the circle of those divisions it is again divided into 32 equal parts, which are called the points of the compass, or rhumbs, each of which is often subdivided into quarters. The initial letters N, NE, &c. are annexed to those rhumbs, to denote the north, north east, &c.

The azimuth compass is nothing more than the above-mentioned compass, to which two sights are adapted, through which the sun is to be seen, in order to find its azimuth, and from thence to ascertain the declination of the magnetic needle.

MAGNETISM *electro*. Among the numerous and important discoveries of the present age, deserves to be ranked the subject of Electro Magnetism, a name given to a class of phenomena first observed by M. Oersted of Copenhagen, in 1819 20, and since then very fully illustrated by M. Ampere, M. Arago, Sir H. Davy, Dr. Wollaston, Mr. Farady, Mr. De la Rive, but more fully still by Mr. Peter Barlow, of the Royal Military Academy, who has published a course of experiments in the science, and described the theory of it, in his excellent Essay on Magnetic Attractions, second edition.

On this subject our limits will only permit us to give the following outline; but the student, who is desirous of more minute information, may profitably consult Mr. Barlow's Essay, and also the supplement to Mr. Partington's Introduction to Electricity.

Let the opposite poles of a voltaic battery be connected by a metallic wire, which may be left of such length as to suffer its being bent or turned in various directions. This is the conjunctive wire of M. Oersted. Let us suppose that the rectilinear portion of this wire is extended horizontally in the line of the magnetic meridian. If a freely suspended compass needle be now introduced, with its centre *under* the conjunctive wire, the needle will instantly deviate from the magnetic meridian; and it will decline towards the *west*, under that part of the conjunctive wire which is nearest the negative electric pole, or the copper end of the voltaic apparatus. The amount of this declination depends on the strength of the electricity, and the sensibility of the needle. Its *maximum* is 90° We may change the direction of the conjunctive wire, out of the magnetic meridian, towards the east or the west, provided it remains above the needle, and parallel to its plane, without any change in the above result, except that of its amount. Wires of platinum, gold, silver, brass, and iron, may be equally employed; nor does the effect cease though the electric circuit be partially formed by water. The effect of the conjunctive wire takes place across plates of glass, metal, wood, water, resin, pottery, and stone. If the conjunctive wire be disposed horizontally *beneath* the needle, the effects are of the same nature as those which occur when it is *above* it; but they operate in an inverse direction; that is to say, the pole of the needle, under which is placed the portion of the conjunctive wire which receives the negative electricity of the apparatus, declines in that case towards the *east*.

To remember these results more readily, we may employ the following proposition: *The pole* ABOVE, *which the negative electricity enters, declines towards the* WEST; *but if it enters* BENEATH *it, the needle declines towards the* EAST.

If the conjunctive wire (always supposed horizontal) is slowly turned about, so as to form a gradually increasing angle with the magnetic meridian, the declination of the needle increases, if the movement of the wire be towards the line of position of the disturbed needle; it diminishes, on the contrary, if it recede from its position. When the conjunc-

tive wire is stretched along-side of the needle in the same horizontal plane, it occasions no declination either to the east or west; but it causes it merely to incline in a vertical line, so that the pole adjoining the negative influence of the pile on the wire dips when the wire is on its west side, and rises when it is on the east. If we stretch the conjunctive wire, either above or beneath the needle, in a plane perpendicular to the magnetic meridian, it remains at rest, unless the wire be very near the pole of the needle; for, in this case, it rises when the entrance takes place by the west part of the

ceive the electricity of the negative end of the battery, the pole of the needle moves towards the *east*; but if we place the wire opposite a point betwixt the pole and the middle of the needle, it moves to the *west*. The phenomena are presented in an inverse order, when the upper extremity of the conjunctive wire receives the electricity of the positive side of the apparatus.

It appears from the preceding facts, says M. Oersted, that the electric conflict (action) is not enclosed within the conducting wire, but that it has a pretty extensive sphere of activity round it. We may also conclude from the observations, that this conflict acts by revolution; for without this supposition we could not comprehend how the same portion of the conjunctive wire, which, placed *beneath* the magnetic pole, carries the needle towards the east, when it is placed *above* this pole, should carry it towards the west. But such is the nature of the circular action, that the movements which it produces take place in directions precisely contrary to the two extremities of the same diameter. It appears also, that the circular movement, combined with a progressive movement in the direction of the length of the conjunctive wire, ought to form a kind of action, which operates *spirally* around this wire as an axis.

The magnetic property may be communicated to a steel needle, or to several needles at once, by the following simple process. Let the conducting wire have one part of it bent into a spiral form, by twisting twenty or thirty times round a ruler of about an inch in diameter, and let the needle be placed either naked in the spiral, or enclosed in a glass tube, or in a tube of any other matter; complete the connexion between the ends of the battery, and in an instant it will be found that the needle has become strongly magnetic, having its north pole towards the zinc extremity of the battery. The same effect may be produced by the discharge of an electrical battery.

Magnetism, *animal*, or, as it has been by some termed, **Mesmerism**, is a pretended science, which some time ago excited much attention in many parts of Europe, and which has still its professors and lecturers in some of the German universities. This doctrine originated with Father Hehl, a German philosopher, who, in 1774, strongly recommended the use of the magnet in medicine; but the founder of the imposture in question was one Mesmer, a physician of the same country, who went to Paris, and flourished in a very extraordinary manner about the years 1778 and 1779. M. Deslon, pupil and coadjutor of Mesmer, is said to have realized 100,000*l.* sterling by his practice; and this person, in explaining the principles of his art, asserted, "That animal magnetism is a universal fluid, constituting an absolute plenum in nature, and the medium of all natural influence between the celestial bodies, and the earth and animal bodies. That it is the most subtile fluid in nature. That the animal body is subjected to the influence of this fluid by means of the nerves, which are immediately affected by it. That the human body, and other bodies, have poles analagous to the magnet. That the virtue of animal magnetism may be communicated from one body to another, either animate or inanimate. That by means of this fluid nervous disorders are cured immediately, and others mediately; and its virtues extend to the universal cure and preservation of mankind," &c.

It is a lamentable case, that, throughout the world, impositions of this nature are always tolerated long enough to answer the purposes of the fabricator, and to encourage others in similar deceptions. Our readers may recollect many instances of notorious character, among which the metallic tractors, which were at one time asserted to be allied to metallic-magnetism, may, perhaps, serve as a proper illustration and proof.

MAGNIFYING, in philosophy, the making of objects appear larger than they would otherwise do; whence convex lenses, which have the power of doing this, are called magnifying glasses; and of such glasses are microscopes constructed.

MAGNITUDE, whatever is made up of parts locally extended, or that has several dimensions; as a line, surface, solid, &c. The apparent magnitude of a body is that measured by the visual angle, formed by rays drawn from its extremes to the centre of the eye; so that whatever things are seen under the same or equal angles, appear equal; and vice versa.

MAGNOLIA, a genus of the polygynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 52d order, coadnatæ. The calyx is triphyllous; there are nine petals; the capsules bivalved and imbricated; the seeds pendulous, and in the form of a berry. There are seven species: the principal are,

1. The *glauca*, or small magnolia, a native of Virginia, Carolina, and other parts of North America. In moist places it rises from seven or eight to fifteen or sixteen feet high, with a slender stem. The wood is white and spongy, the flowers are produced at the extremities of the branches, are white, composed of six concave petals, and have an agreeable scent. 2. The *grandiflora*, or great magnolia, is a native of Florida and South Carolina. It rises to the height of eighty feet or more, with a straight trunk upwards of two feet diameter, having a regular head. The leaves resemble those of the laurel, but are larger, and continue green throughout the year. The flowers are produced at the ends of the branches, and are of a purplish-white colour.

MAHOGANY. See **Swietenia.**

MAHOMETANS, believers in the doctrines and divine mission of Mahomet, the celebrated

warrior and pseudo-prophet of Arabia. In the Mahometan religion we find a prodigious number of rites, ceremonies, and observations, the principal of which are: circumcision, ablutions, fastings, pilgrimage, polygamy, marriage rites, mourning for the dead, funeral rites, and the observance of Friday as a sabbath. See KORAN.

MAIDEN, the name of an ancient instrument for beheading criminals. It is thus described by Mr. Pennant. "This machine of death is now destroyed; but I saw one of the same kind in a room under the parliament house at Edinburgh, where it was introduced by the regent Morton, who took a model of it as he passed through Halifax, and at length suffered by it himself. It is in form of a painter's easel, and about ten feet high: at four feet from the bottom is a cross bar, on which the felon lays his head, which is kept down by another placed above. In the inner edges of the frame are grooves; in these is placed a sharp axe, with a vast weight of lead, supported at the very summit with a peg: to that peg is fastened a cord, which the executioner cutting, the axe falls, and does the affair effectually, without suffering the unhappy criminal to undergo a repetition of strokes, as has been the case in the common method. I must add, that if the sufferer is condemned for stealing a horse or cow, the string is tied to the beast, which, on being whipped, pulls out the peg, and becomes the executioner." This apparatus is now in the possession of the Scottish Antiquarian Society.

MAJESTY, a title given to kings, which frequently serves as a term of distinction.

MAIHEM, or *Maim*, signifies a corporal wound or hurt, by which a man loseth the use of any member. If a man attack another with intent to murder him, and he does not murder the man, but only maim him, the offence is a capital felony; and if any person shall, wilfully maliciously, and unlawfully, shoot at any of his majesty's subjects, or present any kind of loaded fire-arms at any one, and attempt to discharge the same at him, stab or cut any of his Majesty's subjects, with intent to murder or rob, or to maim, disfigure, or disable him, or to do some grievous bodily harm to him, or to obstruct, resist, or prevent the lawful apprehension and detainer of the person so stabbing or cutting, or any of his accomplices, or shall administer poison with intent to murder, or procure the miscarriage of any woman quick with child, he shall be guilty of felony and suffer death.

MAINPRIZE, a delivering a person to his friends, to be answerable for his appearance.

MAINTENANCE, the unlawful taking in hand or upholding a cause of any person. It was formerly unlawful to assist any person in litigation, except as an attorney, advocate, kinsman, servant, or near relation out of charity.

MAJOR, in the art of war, the name of several officers of very different ranks and functions; as, 1. Major-general, the next officer to the lieutenant-general: his chief business is to receive the orders from the general, or in his absence from the lieutenant-general of the day; which he is to distribute to the brigade majors, with whom he is to regulate the guards, convoys, and detachments. When there are two attacks at a siege, he commands that on the left. He ought to be well acquainted with the strength of each brigade, of each regiment in particular, and to have a list of all the field officers. 2. Major of a brigade, the officer who receives the orders from the major-general, and afterwards delivers them to the adjutants of the regiments at the head of the brigade; where he takes and marches the detachments, &c. to the general rendezvous. 3. Major of a regiment, the next officer to the lieutenant-colonel, generally promoted from the oldest captain. He is to take care that the regiment be well exercised, to see it march in good order, and to rally it in case of its being broken. 4. Major of a regiment of horse, is the first captain, who commands in the absence of the colonel. 5. Town-major, the third officer of a garrison, being next to a deputy-governor.

There are also drum-majors, &c. so called from their pre-eminence above others of the same denomination.

MALACHOA, a genus of the class and order monadelphia polyandria. The cal. is common, three-leaved, many-flowered, longer; arils, 5, one-seeded. There are five species, herbs of the West Indies.

MALACHITE, a mineral, the green carbonate of copper, found frequently crystallized in long slender needles; colour green, and the specific gravity about 3.6. It efferverses with nitric acid, and gives a blue colour to ammonia. It decrepitates and blackens before the blowpipe. There are two varieties, the fibrous and the compact; the constituent parts are:—copper, 58.0; carbonic acid, 18.0; oxygen, 12.5; water, 11.5.

MALACOLITE, a mineral found in the silver mines in Sweden, and also in Norway. It is obtained massive and crystallized in six-sided prisms. Specific gravity about 3.25. It consists of silica 53, lime 20, magnesia 19, alumina 3, oxide of iron, &c.

MALATES, in chemistry, salts formed by the union of the malic acid with different bases. The malates of potash, soda, and ammonia, are deliquescent. The malates of potash, soda, ammonia, lime, and barytes, may be formed by dissolving these alkalis in malic acid, and evaporating the solutions.

MALE, among zoologists, that sex of animals which has the parts of generation without the body.

The term male has also, from some similitude to that sex in animals, been applied to several inanimate things; thus we say, a male flower, a male screw, &c.

MALIC *acid*, in chemistry, was discovered by Scheele about the year 1785. It is found in the juices of a great many fruits, and it derives its name from the circumstance of its being obtained in great abundance from the juice of apples, in which it exists ready formed.

The French chemists have ascertained that it may be obtained in the largest quantities from the juice of the sempervivum tectorum, where it exists abundantly combined with lime. Malic acid is very soluble in water, and decomposes spontaneously, by undergoing a kind of fermentation. It is composed of oxygen, hydrogen, and carbon. It combines with alkalis, earths, and metallic oxides, and forms MALATES.

MALLEABLE, a property of metals, whereby they are capable of being extended under the hammer.

MALOPE, a genus of the class and order monadelphia polyandria. The calyx is double, outer three-leaved; arils glomerate, one-seeded. There are two species, herbs of Tuscany, &c.

MALPIGHIA, *Barbadoes cherry*, a genus of the trigynia order, in the decandria class of plants, and in the natural method ranking under the 23d order, trihilatæ. There are 18 species, all of them shrubby evergreens of the warm parts of America, rising with branchy stems from 8 or 10 or 15 or 20 feet high, ornamented with oval and lanceolate entire leaves, and large pentapetalous flowers, succeeded by red, cherry-shaped, eatable berries, of an acid and palatable flavour: and which in the West Indies, where they grow naturally, are used instead of cherries.

MALT, is barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short at the beginning of vegetation. In making malt from barley, the usual method is to steep the grain in a sufficient quantity of water, for two or three days, till it swells, becomes plump, somewhat tender, and tinges the water of a bright-brown, or reddish colour. Then this water being drained away, the barley is removed from the steeping cistern to the floor, where it is thrown into what is called the wet couch; that is, an even heap, rising to the height of about two feet. In this wet couch the capital part of the operation is performed; for here the barley spontaneously heats, and begins to grow, shooting out first the radicle; and if suffered to continue, then the plume, spire, or blade. But the process is to be stopped short at the eruption of the radicle, otherwise the malt would be spoiled. In order to stop it, they spread the wet couch thinly over a large floor, and keep turning it once in four or five hours, for the space of two days, laying it somewhat thicker each time. After this, it is again thrown into large heaps, and there suffered to grow sensibly hot to the hand, as it usually will in 20 or 30 hours time; then being spread again, and cooled, it is thrown into the kiln, to be dried crisp without scorching.

MALTA, KNIGHTS OF, or otherwise called *hospitalers of St. John of Jerusalem*, a religious military order, whose residence is in the Island of Malta. The order consisted of three estates, the knights chaplains, and servants at arms: there are also priests who officiate in the churches, friar-servants who assist at the offices, and donnes or demicrosses, but these are not reckoned constituent parts of the body; the government of the order was partly monarchical, and partly aristocratical; the grand master being sovereign. None are admitted into this order but such as are of noble birth.

MALTHA, in antiquity, a kind of cement, of which there were two sorts, native and factitious: one of the latter sort, much in use, consisted of pitch, wax, plaister, and grease. Another kind used by the Romans in their aqueducts, was made of lime slacked in wine, incorporated with melted pitch, and fresh figs. Natural maltha is a kind of bitumen, with which the Asiatics plaister their walls; and which being once set on fire, water makes it burn more fiercely.

MALVA, the *mallow*, a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is double the exterior one triphyllous; the arilla numerous and monospermous. There are 34 species, consisting of herbaceous perennials, biennials, and annuals, for medical, economical, and ornamental uses.

MAMALUKES, the name of a dynasty that reigned in Egypt. The Mamalukes were originally Turkish and Circassian slaves, bought of the Tartars by Melicsaleh, to the number of a thousand, whom he bred up to arms, and raised some to the principal offices of the empire. They killed Sultan Mondam, whom they succeeded.

Some say that the Mamalukes were ordinarily chosen from among the Christian slaves, and that they were the same with the Janissaries among the Turks. They never married: they first are said to have been brought from Circassia, and some have supposed that they began to reign about the year 869.

MAMMÆ, the breasts, in anatomy. See MAMMARY *gland*.

MAMMALIA, the first class of animals in the Linnæan system: the animals in this class have lungs that respire alternately; jaws incumbent, covered; teeth usually within; teats lactiferous; organs of sense, tongue, nostrils, eyes, ears, and papillæ of the skin; coverings, hair, which is scanty in warm climates, and scarcely any on aquatics; supporters, four feet, except in aquatics, and in most a tail; walk on the earth and speak. Such is the Linnæan account. They suckle their young by means of lactiferous teats, and hence the name mammallia. In structure they resemble man; most of them are quadrupeds, and with man inhabit the surface of the earth: a few of them exist in the ocean. There are seven orders, the characters of which are taken from the number situation, and structure of the teeth. The names of the orders are:—

Belluæ,
Bruta,
Cete,
Feræ,
Glires,
Pecora,
Primates,

which see.

MAMMARY *gland*, in anatomy, is a glandular substance situated in the breast, and secreting the milk.

This gland, surrounded by cellular and adipous substance, and covered by the common integuments, constitutes the breast. It lies on the anterior surface of the pectoralis major muscle.

MAN. See ZOOLOGY.

MANDAMUS, is a writ issuing in the king's name out of the court of king's bench, and directed to any person, corporation, or inferior court of judicature, commanding to some particular thing therein specified, as appertaining to their office and duty.

MANDRAKE. See ATROPA.

MANDREL, a kind of wooden pulley, making a member of the turner's lathe, of which there are several kinds, as the flat mandrels, which have three or more little pegs or points near the verge, and are used for turning flat boards on; the pin mandrel are those which have a long wooden shank to fit into a large hole made in the work to be turned; hollow

mandrels are those hollow of themselves, and used for turning hollow work; screw mandrels for turning screws, &c.

MANETTIA, a genus of the class and order tetrandria monogynia. The calyx is eight-leaved: corolla four-cleft; capsule inferior, two-valved, one-celled; seeds imbricate, unilocular. There are three species, shrubs of the West Indies.

MANGANESE. 1. The dark grey, or brown mineral called manganese has been long known and used in the manufacture of glass. A mine of it was discovered in England by Mr. Boyle. A few experiments were made upon this mineral by Glauber in 1656. Manganese, when pure, is of a greyish-white colour, and has a good deal of brilliancy. Its texture is granular. It has neither taste nor smell. Its hardness is equal to that of iron. Its specific gravity is 8.0. It is very brittle; and can neither be hammered, nor drawn out into wire. Its tenacity is unknown. It requires, according to Morveau, the temperature of 160° Wedgewood to melt it; so that, platinum excepted, it is the most infusible of all the metals. When reduced to powder it is attracted by the magnet, owing probably to a small portion of iron from which it can with difficulty be parted. Manganese, when exposed to the air, attracts oxygen more rapidly than any other body, phosphorus excepted. It loses its lustre almost instantly, becomes grey, violet, brown, and at last black. These changes take place still more rapidly if the metal is heated in an open vessel.

Concentrated sulphuric acid attacks manganese, at the same time that hydrogen gas is disengaged. If sulphuric acid be added, and drawn off by distillation several times from the black oxide, by a heat nearly approaching to ignition, in a glass vessel, it is found that oxygen gas is disengaged toward the end of each process, and part of the oxide is dissolved. The solution of the sulphate made from the metal itself is colourless. If it be made from the black oxide, it is a purplish red; but this colour is destroyed by the light of the sun, and again restored by removing the solution into the dark. Sulphurous acid dissolves the oxide, taking part of its oxygen, which converts it into sulphuric acid, thus forming a sulphate with the remaining oxide. Nitric acid dissolves manganese with effervescence, and the escape of nitrous gas. A spongy, black, and friable matter remains, which is a carburet of iron. The solution does not afford crystals. The oxide is more readily soluble in nitrous acid. Manganese is dissolved in the usual manner by muriatic acid. The solution of manganese in muriatic acid scarcely affords crystals; but a deliquescent saline mass by evaporation, which is soluble in alcohol. In the dry way, the oxide of manganese combines with such earths and saline substances as are capable of undergoing fusion in a strong heat. These experiments are most advantageously performed by the blowpipe, which see. This metal melts readily with most of the other metals, but rejects mercury. Gold and iron are rendered more fusible by a due addition of manganese; and the latter metal is rendered more ductile. Copper becomes less fusible, and is rendered whiter, but of a colour subject to tarnish.

The ore of manganese, which is known in Derbyshire by the name of *black wadd,* is remarkable for its spontaneous inflammation with oil. It is of a dark-brown colour, of a friable earthy appearance, partly in powder, and partly in lumps. If half a pound of this be dried before a fire, and afterward suffered to cool for about an hour, and it be then loosely mixed or kneaded with two ounces of linseed oil; the whole, in something more than half an hour, becomes gradually hot, and at length bursts into a flame. This effect wants explanation. It seems, in some measure, to resemble the inflammation of oils by the nitric acid. Manganese was used chiefly by glass-makers and potters, but the important discovery of chlorine has greatly extended its utility.

MANGIFERA, the *Mango-tree*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the plum kidney-shaped. There are three species, the principal of which is a native of many parts of the East Indies, whence it has been transplanted to Brazil, and other warm parts of America.

MANICHEES, in church history, a sect of christian heretics in the third century, the followers of Manes, who pretended to be the Comforter whom our Saviour promised to send into the world. He taught that there are two principles or gods, co-eternal and independent on each other; the one the author of all evil, and the other of all good: a doctrine which he borrowed from the Persian magi.

MANILLE, in commerce, a large brass-ring, in the form of a bracelet, either plain or engraven, flat or round. Manilles are the principal commodities which the Europeans carry to the coast of Africa, and exchange with the natives for slaves. These people wear them as ornaments on the small of the leg and on the thick part of the arm above the elbow.

MANIPULUS, in Roman antiquity, a body of infantry, consisting of 200 men, and constituting the third part of a cohort.

MANIS, a genus of quadrupeds of the order of bruta. The generic character is, teeth none; tongue cylindric and extensile; mouth narrowed into a snout; body covered with scales. The genus manis presents an appearance not less extraordinary than that of dasypus or armadillo; being covered on every part, except on the belly, with strong and large horny scales, constituting a suit of armour, and capable of defending the animal when rolled up,

1. *Manis tetradactyla*, long-tailed manis, known in India by the name of the phatagen, is of a very long and slender form: the head is small; the snout narrow; the whole body, except beneath, covered with broad but sharp-pointed scales, which are striated throughout their whole length; the tail is more than twice the length of the body, and tapers gradually to the tip. The legs are very short, scaled like the body, and on each of the feet are four claws, of which those on the fore-feet are much stronger then those of the hind. The colour of the whole animal is an uniform deep brown.

2. *Manis pentadactyla*, short-tailed manis, differs from the former, in being of a much thicker and shorter form; the tail in particular, differs greatly in proportion from that of the preceding, being not so long as the body, very thick at the base, and thence gradually tapering, but terminating very obtusely. The head is

small as in the former; the ears small and rounded; the feet furnished with five toes each, of which those on the fore feet are extremely strong, except the exterior one, which is much smaller than the rest. The whole animal is covered with thick, strong, and large scales, which in the full grown specimens are perfectly smooth, but in those which are smaller are slightly striated about half way from the base.

MANNA. Several vegetables afford manna; but the ash, the larch, and the alhagi, afford it in the largest quantities. The ash which affords manna grows naturally in all temperate climates; but Calabria and Sicily appear to be the most natural countries to this tree. The manna flows naturally from the tree, and attaches itself to its sides in the form of white transparent drops; but the extraction of this juice is facilitated by incisions made in the tree during summer. Its smell is strong, and its taste sweetish and slightly nauseous: if exposed on hot coals, it swells up, takes fire, and leaves a light bulky coal. Water totally dissolves it, whether hot or cold. If it be boiled with lime, clarified with white of egg, and concentrated by evaporation, it affords crystals of sugar. Manna affords, by distillation, water, acid, oil, and ammonia; its coal affords fixed alkali. This substance forms the basis of many purgative medicines.

MANOMETER, or *Manoscope*, an instrument to shew or measure the alterations in the rarity or density of the air. It differs from the barometer in this, that the latter only serves to measure the weight of the atmosphere, but the former the density of the air in which it is found; which density depends not only on the weight of the atmosphere, but also on the action of heat, cold, &c.

MANOR, was a district of ground held by lords or great personages, who kept in their own hands so much land as was necessary for the use of their families, which were called terræ dominicales, or demesne lands. The other lands they distributed among their tenants. The residue of the manor being uncultivated, was termed the lord's waste, and served for common of pasture to the lord and his tenants. All manors existing at this day must have existed as early as king Edward the First.

MANSLAUGHTER. See HOMICIDE.

MANTELETS, in the art of war, a kind of moveable parapets, made of planks about three inches thick, nailed one over another, to the height of almost six feet, generally cased with tin, and set upon little wheels, so that in a siege they may be driven before the pioneers, and serve as blinds to shelter them from the enemy's small shot.

MANTIS, a genus of insects of the order hemiptera. The generic character is, head unsteady, armed with jaws, and furnished with palpi or feelers; antennæ setaceous; thorax linear; wings four, membranaceous, convoluted; fore legs, in most species, compressed, serrated beneath, and armed with a single claw and a setaceous, lateral, jointed foot; hind legs smooth, formed for walking. This is one of the most singular genera in the whole class of insects; and imagination itself can hardly conceive shapes more strange than those exhibited by some particular species. The chief European kind is the mantis oratoria of Linnæus, or camel cricket, [illegible]s often called. This is found in most of the warmer parts of Europe, and is of a beautiful green colour. It is nearly three inches in length, of a slender shape, and in its general sitting posture is observed to hold up the two fore legs, slightly bent, as if in an attitude of prayer. In its real disposition it is very far from sanctity, preying with great rapacity on any of the smaller insects which fall in its way. It is also of a very pugnacious nature; and when kept with others of its own species in state of captivity, will attack its neighbour with the utmost violence, till one or the other is destroyed in the contest.

MANURES. See AGRICULTURE.

MAP, a plane figure, representing the surface of the earth, or a part thereof. In maps these three things are essentially requisite. 1. That all places have the same situation and distance from the great circles therein, as on the globe, to shew their parallels, longitudes, zones, climates, and other celestial appearances. 2. That their magnitudes be proportionable to their real magnitudes on the globe. 3. That all places have the same situation, bearing, and distance, as on the earth itself.

The true chart performs the first and last of these very exactly, but fails extravagantly in the second; and indeed no kind of projection yet found can exhibit more than two of them at once, by reason of the great difference between a plane and convex superfices. The degrees of longitude are always numbered at top and bottom, and the degrees of latitude on the east and west sides. In all right-lined and general circular maps, except those of Wright's projection, the degrees of latitude on the sides are of an equal breadth; and in all circular and right lined maps, except the said Wright's and the plane charts, the degrees of longitude are unequal.

In general maps. the circles corresponding to those in the heavens are inscribed, viz. the equator is expressed by a straight east and west line; and the first meridian, the polar circles, the tropics, and the other meridians and parallels, which are drawn at every five or ten degrees, intersect each other at right angles. There may be as many different projections as there are points of view in which a globe can be seen, but geographers have generally chosen those which represent the poles at the top and bottom of the map; these from the delineation of the lines of latitude and longitude, are called the stereographic, orthographic, and globular projections.

We shall not detain the reader with a description of all the projections, some of which are so erroneous as to deserve being consigned entirely to oblivion. But as the projection of maps is a pleasing and instructive exercise, and indeed indispensably necessary to the right understanding of geography to students, we shall here subjoin a few examples of construction, which, if the student carefully imitate, he will find little if any difficulty in projecting a map of any given portion of the earth's surface.

Geometrical construction of the Globular Projection.

From the centre C, plate XXIX, fig. 1, with any radius, as CB, describe a circle; draw the diameters AB, and 90, 90, at perfect right angles to one another, and divide them in-

to nine equal parts; likewise divide each quadrant into nine equal parts; each of which contains ten degrees; if the scale admits of it, each of these divisions may be subdivided into degrees; next, to draw the meridian, suppose the meridians 80° W. of Greenwich, we have given the two poles 90, 90, and the point 80 in the equator, or diameter AB; describe a circle to pass through the three given points as follows: with the radius 90 set one foot of the compasses on the point 90, and describe the semicircles XX and ZZ, then remove the compasses to the point 80 on the equator, and describe the arcs, 1, 1, and 2, 2; where they intersect the semicircle; make the point, as at 1 and 2, and draw lines from 2 through the point 1 till they intersect the diameter BA continued in E: then will E be the centre from whence the meridian 90, 80, 90, must be drawn, and will express the meridian of 80° W. longitude from Greenwich; the same radius will draw the meridian expressing 140° W. longitude: in like manner, draw the next meridian with the radius CB, set one foot of the compasses in the point *d*, and describe the arcs *aa* and *bb*, then draw lines as before, which will give the point D, the centre of 90° W, longitude; so of all the rest. The parallels of latitude are drawn in the same manner, with this difference, that the semicircles XX and ZZ must be drawn from the points A and B, the extremities of the equator.

In the manner above described, Mr. Arrowsmith, drew all the meridians and parallels of latitude to every degree on two hemispheres, which laid the foundation of his excellent map of the world.

We shall now shew how the same thing may be done mechanically.

(1) *The Globular Projection of the Sphere on the Plane of a Meridian.*

Draw the circle WNES fig. 2, draw the two diameters NS and WE at right angles with each other.

Divide the arc of each quadrant into nine equal parts.

Divide the radii also in the same manner into ninety equal parts, A *b*.

The diameter N *b* is the meridian, and the diameter WE is the equator.

The other meridians are arcs of circles, for each of which, as we have seen, there are three given points through which it must pass, and those are the two poles NS, and a division on the semi-diameter WC, viz. either *a*, *b*, *c*, *d*, *e*, *f*, *g*, or *h*. The centres for these arcs will be in the line CE produced; and the centres for those on the other side will be on the line CW produced.

For the arc S*a*N. the rad. *aa* = 90,61
— S*b*N. — *bb* = 92,82
— S*c*N. — *cc* = 97,32
— S*d*N. — *dd* = 106
— S*e*N. — *ee* = 121,1
— S*f*N. — *ff* = 149,7
— S*g*N. — *gg* = 215,6
— S*h*N. — *hh* = 410,7

of the par[ts] of which the r[ad]ius contains 90.

And for each of the arcs representing the parallels of lat. also there are three given points, viz. one of the divisions *k*, *l*, *m*, *n*, *o*, *p*, *q*, or *r*, upon the meridian SN, and the two corresponding divisions of the circumference. The centres for these arcs will fall on the line SN, produced both ways, and the following table shews the length of the radius of each equal part, in equatorial degrees, as in the former case.

For the arc

80	*r* 80	the radius	*rr*	=	18,44
70	*q* 70	—	*qq*	=	39,75
66½	A.66½	—	A *Arctic*	=	48,19
60	*p* 60	—	*pp*	=	65,3
50	*o* 50	—	*oo*	=	97,71
40	*n* 40	—	*nn*	=	143
30	*m* 30	—	*mm*	=	210
23½	T. 23½	—	T. *Tropic*	=	281,4
20	*l* 20	—	*ll*	=	337,6
10	*k* 10	—	*kk*	=	708,5

Of the equal parts of which the radius contains 90.

To project a Map of any particular part of the World.

There are several methods of projecting particular parts of the world, we shall notice only two. First, when the meridians and parallels of latitude are right lines.

To project a map of England after this method. England is situated between 2° E. and 6° 20′ W. from Greenwich, and between 50° and 56° N. lat.

Draw a base line AB, plate XXX, fig. 1, in the middle of which erect the perpendicular CD.

Assume a distance for a degree of lat. and set off as many degrees on CD as are wanted, which in this instance are 6; but as a little space beyond the limits of the country is generally left, set off 7.

Through these points draw lines parallel to AB, which will be parallels of latitude.

Respecting the degrees of longitude it must be observed, that on the equator they would be of the same length as they are on a meridian, but must gradually decrease from thence to 0 at the poles.

The following table exhibits the length in geographical miles, of a degree of longitude for every degree of latitude.

Deg Lat.	Geograph. Miles.	Deg. Lat.	Geograph. Miles.	Deg. Lat.	Geograph. Miles.
0	60,00	31	51,43	61	29,09
1	59,99	32	50,88	62	28,17
2	59,96	33	50,32	63	27,24
3	59,92	34	49,74	64	26 30
4	59,85	35	40,15	65	25,36
5	59,77	36	48,54	66	24,41
6	59,67	37	47,92	67	23,41
7	59,56	38	47,28	68	22,48
8	59,42	39	46,63	69	21,50
9	59,28	40	45,96	70	20,52
10	59,00	41	45,28	71	19,53
11	58,90	4	44,59	72	18,54
12	58,69	4.,	43,38	73	17,54
13	58,46	44	43,16	74	18,53
14	58,22	45	42,43	75	15,53
15	57,96	46	41,68	76	14,52
16	57,67	47	40,92	77	13,50
17	57,38	48	40,15	78	12,47
18	57 06	49	39,36	79	11,45
19	56,73	50	38,57	80	10,42
20	56,38	51	38,76	81	9,38
21	56,02	52	36.94	82	8,34
22	55,63	53	26,11	83	7.31
23	55,23	54	35,27	84	6,27
24	54,81	55	34,41	85	5,23
25	54,38	56	33,55	86	4,18
26	53,93	57	32,68	87	3,14
27	53,46	58	31,79	88	2,09
28	52,97	59	30,90	89	1,04
29	52,47	60	30,00	99	0,00
30	51,96				

To use this table, divide the assumed degree into sixty parts by a diagonal line, fig. 2; look for the number of miles answering to the degree of lat. 49, which is 39, 36, say 39½, which take off the scale, fig. 2, at *a*, and set off four times from C towards A, and the same from C towards B. The top meridian is 56° deg. of lat opposite which, in the table, is 33, 35, say 33½, which take from the scale, fig. 9, at *b*, and set off four times from D towards E, and the same from D towards F. Draw the meridian lines to the corresponding divisions at top and bottom, of which 0 0 is the meridian of London.

Secondly. When the meridians and parallels are curved lines.

To project a map of Europe by this method. Draw a base line GH, fig. 3. in the middle of which erect the perpendicular JP, and assume any distance for 10° of latitude.

Europe extends from 36° to 72° N. lat.

Let the point J be 30°, from which set off six of the assumed distances to P, which will be the N. pole.

Number the distances 40, 50, 60, &c.

On the centre P, describe arcs passing through the points of division on the line JP, which will be parallels of latitude.

Divide the space assumed for 10° of lat. into 60 parts by a diagonal line, fig. 11.

Look into the foregoing table for the number of miles answering to 30°, which is 51, 96, say 52, which take from the scale, fig. 4, at *b*.

Set this distance off on the arc 30, 30, from the centre line JP both ways.

Do the same for 40°, 50°, 60°, &c.

Through the corresponding divisions, on all the arcs, draw curve lines; which will represent the meridians.

Number the degrees of lat. and long., which will complete the diagram.

Those who wish to prosecute this interesting branch of science to a greater extent than the above sketch comprehends, may consult with profit Jamieson's Treatise on the Construction of Maps.

MAPLE, in botany, is of the genus Acer. Of the several species the most important is the A. saccharinum, or American sugar apple, from which the Americans derive sugar in large quantities, by tapping the trees early in the spring, and boiling the juice. For this purpose large tracts of lands in North America are devoted to the culture of this tree, which yields a sugar equal to the best cane, and which requires no other labour than what women and girls can bestow, in drawing off and boiling the liquor; and when skilfully tapped, the tree will last many years. A tree of an ordinary size yields in a good season from twenty to thirty gallons of sap, from which may be made from five to six pounds of sugar. The tree is tapped with an auger, first on the south side and then on the north, and the sap will flow five or six weeks according to the temperature of the weather.

MARANTA, *Indian arrow-root*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. The corolla is ringent and quinquefid, with two segments alternately patent. There are five species, all of them herbaceous perennial exotics of the Indies. They have thick, knotty, creeping roots, crowned with long, broad, arundinaceous leaves, ending in points, and upright stalks, half a yard high, terminated by bunches of monopetalous, ringent, five-parted flowers. The root of the galanga is used by the Indians to extract the virus communicated by their poisoned arrows: whence it has derived its name. The arundinacea, or starch plant, rises to two feet, has broad pointed leaves, small white flowers, and one seed. It is cultivated in gardens and in provision grounds in the West Indies; and the starch is obtained from it by the following process. The roots when a year old are dug up, well washed in water, and then beaten in wooden mortars to a pulp. This is thrown into a tub of clean water. The whole is then well stirred, and the fibrous part wrung out by the hands, and thrown away. The milky liquor being passed through a hair-sieve, or coarse cloth, is suffered to settle, and the clear water is drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water, and drained: lastly, the mass is dried on sheets in the sun, and is pure starch.

MARBLE, in natural history, a genus of fossils, composed chiefly of lime; being bright and beautiful stones, moderately hard not giving fire with steel, fermenting with, and soluble in, acid menstrua, and calcining in a slight fire. It is of so hard, compact, and fine a texture as readily to take a fine polish, and is much used in ornaments of buildings, as columns, statues, altars, tombs, chimney-pieces, tables, and the like. There are many different kinds of marble. Some are of one simple colour, as white or black; others variegated with stains, clouds, waves, and veins: but all opaque, excepting the white, which, cut into thin pieces, becomes transparent. Marble is found in considerable quantities, in most of the mountainous parts of Europe. Derbyshire abounds in this article. Near Kemlyn Bay, in the island of Anglesea, there is a quarry of beautiful marble, called Verde di Corsica, being common to this place, some parts of Italy, and Corsica. Its colours are green, black, white, and dull purple, irregularly disposed. Italy is that part of Europe which produces the most valuable marble, and in which its exportation makes a considerable branch of foreign commerce. The black and the milk-white marble, coming from Carara, a town in the duchy of Massa, are particularly esteemed.

Marble, *polishing of*, is performed by first rubbing it well with a free stone, or sand, till the strokes of the axe are worn off, then with pumice-stone, and afterwards with emery.

MARBLING, in general, the painting any thing with veins and clouds, so as to represent those of marble. Marbling of books or paper is performed thus: Dissolve four ounces of gum-arabic into two quarts of rain water; then provide several colours mixed with water in pots or shells, and with pencils peculiar to each colour, sprinkle them by way of intermixture upon the gum-water, which must be put in a trough, or some broad vessel; then with a stick curl them, or draw them out in streaks, to as much variety as may be done. Having done this, hold your book or books close together, and only dip the edges in, on the top of the water and colours, very lightly; then take them off, and the plain impression of the colours in mixture will be upon the leaves.

MARCGRAVIA, a genus of the polyandria monogynia class of plants, the corolla whereof consists of a single petal, of a conico-oval figure; and its fruit is a globose berry, with a single cell, containing a great number of very small seeds. There is one species, a shrub of the West Indies.

MARE. See Equus.

MARINE a general name for the navy of a kingdom or state; as also the whole economy of naval affairs, or whatever respects the building, rigging, arming, equipping, navigating, and fighting ships. It comprehends likewise the government of naval armaments, and the state of all the persons employed therein, whether civil or military.

Marine *acid*. See Muriatic *acid*.

Marine-*chair*, a machine invented for viewing the satellites of Jupiter at sea, and thereby determining the longitude of their eclipses.

Marine *remains*, a term used to express the shells of sea-fishes, and parts of crustaceous and other sea-animals, found in digging at great depths in the earth, or on the tops of high mountains. Being found in these situations, is an evident and unquestionable proof of the sea having been once there, since it must have covered those places where it has left its productions.

Mariner's *compass*. See Magnetism.

MARINES, a body of soldiers raised for the sea service, and trained to fight either in a naval engagement, or in an action at shore. The direction of this body is vested in the Lords Commissioners of the Admiralty. It is stationed in three divisions, o at Chatham, one at Portsmouth, and another at Plymouth.

MARITIME, something relating to, or bounded by the sea; thus, a maritime province, or country, is one bounded by the sea; and a maritime kingdom or state is one that makes a considerable figure, or is very powerful at sea. Hence, by maritime powers, among the European states, are understood Great Britain and Holland.

MARK, or Marc, denotes a weight used in several states of Europe, and for several commodities, especially gold and silver. In France, the mark is divided into 8 *oz.* or 64 drachms, 92 derniers or penny weights, or 160 esterlines. or 300 mailles, or 640 felins, or 4608 grains. In Holland the mark-weight is also called troy-weight, and is equal to that of France. When gold and silver are sold by the mark, it is divided into 24 carats.

Mark is also used for a money of account The English mark is two-thirds of a pound sterling. or 13*s.* 1*d.* and the Scotch mark is of equal value in Scotch money of account. The mark-lubs, used at Hamburgh as a money of account, are equal to one-third of the rix dollar; each mark is divided into 16 sols-lubs. Mark is also a copper and silver coin in Sweden.

MARKET. A market is less than a fair, and is commonly held once or twice a week. According to Bracton, one market ought to be distant from all others at least six miles and a half and a third of a half: but no market is to be kept within seven miles of the city of London; but all butchers, victuallers, &c. may hire stalls and standings in the flesh-markets there, and sell meat and other provisions, four days in a week. Every person who has a market is entitled to receive toll for the things sold in it. In London, every shop in which goods are exposed publicly to sale, is market overt for such things only as the owner professes to trade in: though if the sale is in a warehouse, and not publicly in the shop, the property is not altered. If a man buy his own goods in a market, the contract shall not bind him unless the property had been previously altered by a former sale.

MARLE. A mixture of carbonat of lime and clay, in which the carbonat considerably exceeds the other ingredient, is called marle. Its structure is earthy. Opaque, sometimes in powder. Specific gravity from 1.6 to 2.877. Colour usually grey, often tinged with other colours. Effervesces with acids. Some marles crumble into powder when exposed to the air; others retain their hardness for many years. Marles may be divided into two varieties: 1. Those which contain more silica than alumina. 2. Those which contain more alumina than silica. Mr. Kirwan has called the first of these siliceous, the second argillaceous marles. Attention should be paid to this distinction when marles are used as a manure.

Marle, *bituminous*, is found in different parts of Germany. Colour greyish or brownish-black. Found massive. Shistose. Plates flat or waved. Opaque. Feels soft. Easily broken. Moderately heavy. Effervesces with acids. Burns before the blowpipe, leaving black scoriæ.

MARLINS, in artillery, are tarred white skains, or long wreaths or lines of untwisted hemp, dipped in pitch or tar, with which cables and other ropes are wrapped round, to prevent their fretting and rubbing in the blocks or pulleys through which they pass.

MARMOTTE. See Mus.

MARQUE. See Letters *of Marque*.

MARQUETRY, or *inlaid work*, is a curious work composed of several fine hard pieces of wood, of various colours fastened in thin slices on a ground, and sometimes enriched with other matters, as silver, brass, tortoise-shell, and ivory. The ground on which the pieces are to be arranged and glued is usually of well-dried oak or deal; and is composed of several pieces glued together, to prevent its warping The wood to be used in marquetry is reduced into leaves of the thickness of a line, or the 12th part of an inch, and is either of its natural colour or stained, or made black to form the shades by other methods; this some perform by putting it in sand heated very hot over the fire; others by steeping it in lime-water and sublimate; and others in oil of sulphur The wood being of the proper colours, the contours of the pieces are formed according to the parts of the design they are to represent: this is the most difficult part of marquetry, and that which requires the most patience and attention. The two chief instruments used in this work are a saw and a wooden vice, which has one of its chaps fixed, and the other moveable; which is open and shut by the foot, by means of a cord fastened to a treadle.

MARQUIS, a title of honour, next in dignity to that of duke, first given to those who commanded the marches, that is, the borders and frontiers of countries.

Marquises were not known in England till the reign of king Richard II. and the year 1337.

MARRIAGE, a contract, both civil and religious, between a man and a woman. Taking marriage in the light of a civil contract, the law treats it as it does all other contracts: allowing it to be good and valid in all cases where the parties at the time of making it, were, in the first place, willing to contract; secondly, able to contract; and, lastly, actually did contract in the proper forms and solemnities required by law.

By several statutes a penalty of 100*l.* is inflicted for marrying any persons without banns or licence. But by 25 G. II, c. 33, if any person shall solemnize matrimony without banns or licence obtained from some persons having authority to grant the same, or in any other place than a church or chapel where banns have been usually published, unless by special licence from the archbishop of Canterbury, he shall be guilty of felony, and transported for 14 years, and the marriage shall be void.

MARROW. See ANATOMY.

MARRUBIUM, *white horehound*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The calyx is salver-shaped, rigid, and tenstriated; the upper lip of the corolla bifid, linear, and straight. There are 11 species, the most remarkable of which is the vulgare, a native of Britain, growing naturally in waste places, and by way-sides near towns and villages, but not common. It has a strong and somewhat musky smell, and bitter taste.

MARS, in astronomy, one of the superior planets, moving round the sun in an orbit between those of the earth and Jupiter.

MARSHAL, in its primary signification, means an officer who has the command or care of horses; but it is now applied to officers who have very different employments, as earl-marshal, knight-marshal, or marshal of the king's house, &c.

MARSHAL *of the king's bench*, an officer who has the custody of the king's bench prison in Southwark. This officer is obliged to give his attendance, and to take into his custody all persons committed by that court.

MARSHAL *of the exchequer*, an officer to whom that court commits the king's debtors.

MARSHALLEA, a genus of the class and order syngenesia polygamia æqualis, little known.

MARSHALLING a coat in heraldry, is the disposal of several coats of arms belonging to distinct families, in one and the same escutcheon or shield, together with their ornaments, parts, and appurtenances.

MARSHALSEA-*court*, is a court of record, originally instituted to hear and determine causes between the servants of the king's household and others within the verge of the court, and has jurisdiction of things within the verge of the court, and of pleas of trespass, where either party is of the king's family; and of all other actions personal, wherein both parties are the king's servants; but the court has also power to try all personal actions, as debt, trespass, slander, trover, action on the case, &c. between party and party, the liberty whereof extends 12 miles about Whitehall. The judges of this court are the steward of the king's household, and high-martial for the time being; the steward of the court, or his deputy, is generally an eminent counsel. If a cause of importance is brought in this court it is generally removed into the court of king's bench or common pleas by a habeas corpus cum causa.

MARSILEA, a genus of the cryptogamia class of plants, without any corolla or cup; the antheræ are four, and placed on an obtusely conic-body; the fruit is of a roundish figure, consisting of four cells, in each of which are contained several roundish seeds. There are three species.

MARTIAL LAW, is the law of war, which entirely depends on the arbitrary power of the prince, or of those to whom he has delegated it. For though the king can make no laws in time of peace without the consent of parliament, yet in time of war he uses an absolute power over the army.

MARTIN. See HIRUNDO and MUSTELA.

MARTLETS, in heraldry, little birds represented without feet, and used as a mark of distinction for younger brothers.

MARTNETS, in a ship, small lines fastened to the leach of a sail, reeved through a block on the topmast-head, and coming down by the mast to the deck.

MARTYNIA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 10th order, personatæ. There are 60 species, tender, herbaceous, flowery plants of South America.

MARYGOLD. See CALENDULE; and for MARSH-MARYGOLD, see CALTHA.

MASON, a person employed under the direction of an architect in the raising of a stone building. The chief business of a mason is to make the mortar; raise the walls from the foundation to the top, with the necessary retreats and perpendiculars; to form the vaults, and employ the stones as delivered to him. When the stones are large, the business of hewing or cutting them belongs to the stone-cutters, though these are frequently confounded with masons: the ornaments of sculpture are performed by carvers in stones or sculptors. The tools or implements principally used by them are the square, level, plumb-line, bevel, compass, hammer, chissel, mallet, saw, trowel, &c. Besides the common instruments used in the hand, they have likewise machines for raising of great burdens, and the conducting of large stones, the principal of which are the lever, pulley, wheel and axis, crane, &c.

MASONS, *free and accepted*, a very ancient society or body of men, so called, either from some extraordinary knowledge of masonry which they are supposed to be masters of, or because the first founders of the society were persons of that profession. These are now very considerable, both for number and character, being found in every country in Europe, and consisting principally of persons of merit and consideration. As to antiquity, they lay claim to a standing of some thousand years.

MASONRY, in general, a branch of architecture, consisting in the art of hewing or squaring stones, and cutting them level or perpendicular, for the uses of building; but in a more limited sense, masonry is the art of assembling and joining stones together with mortar.

MASSETER, in anatomy, a muscle which has its origin in the lower and interior part of

the jugum, and its end at the external superficies of the angle of the jaw.

MAST, a long round piece of timber, elevated perpendicularly upon the keel of a ship, upon which are attached the yards, the sails, and the rigging, in order to their receiving the wind necessary for navigation.

MASTER *of arts*, is the first degree taken up in foreign universities, and for the most part in those of Scotland, but the second in Oxford and Cambridge; candidates not being admitted to it till they have studied seven years in the university.

Master *in chancery*. The masters in chancery are assistants to the Lord Chancellor and master of the Rolls; of these there are some ordinary, and some extraordinary: the masters in ordinary are twelve in number, some of whom sit in court every day during the term, and have referred to them interlocutory orders for stating accounts, and computing damages and the like; and they also administer oaths, take affidavits, and acknowledgments of deeds and recognizances. The Masters-extraordinary are appointed to act in the country, in several counties of England, beyond ten miles distant from London.

Master *of the faculties*, an officer under the archbishop of Canterbury, who grants licences and dispensations.

Master *of the horse*, a great officer of the crown, who orders all matters relating to the king's stables, races, breed of horses, and commands the equerries and all the other officers and tradesmen employed in the king's stables.

Master *of the ordnance*, a great officer, who has the chief command of the king's ordnance and artillery.

Master *of the rolls*, is an assistant to the Lord Chancellor of England in the high court of chancery; and in his absence hears causes there, and gives orders.

Master *of a ship*, the same with captain in a merchantman; but in a king's ship he is an officer who inspects the provisions and stores, and acquaints the captain with what is not good, takes particular care of the rigging and of the ballast, and gives directions for stowing the hold; he navigates the ship under the directions of his superior officer.

Master *at arms*, in a king's ship, an officer who daily, by turns, as the captain appoints, is to exercise the petty officers and ship's company; to place and relieve sentinels; to see the candles and fire put out according to the captain's orders; to take care the small arms are kept in good order, and to observe the directions of the lieutenant at arms.

Master *of the Temple*, since the dissolution of the order of the Templars, the spiritual guide and pastor of the temple is so called, which was the denomination of the founder and his successors.

Master and **servant**. In London and other places the mode of hiring is by what is commonly called a month's warning, or a month's wages: that is, the parties agree to separate on either of them giving to the other a month's notice for that purpose; or in lieu thereof, the party requiring the separation to pay, or give up, a month's wages. But if the hiring of a servant is general, without any particular time specified, it will be construed to be a hiring for a year certain; and in this case if the servant depart before the year, he forfeits all his wages. And where a servant is hired for one year certain, and so from year to year as long as both parties shall agree, and the servant enters upon a second year, he must serve out that year, and is not merely a servant at will after the first year. If a woman servant marries she must nevertheless serve out her term.

If a servant be disabled in his master's service by an injury received through another's default, the master may recover damages for loss of his service. And a master may not only maintain an action against any one who entices away a servant, but also against the servant: and if without any enticement a servant leaves his master without just cause, an action will lie against another who retains him with a knowledge of such departure.

A master has a just right to expect and exact fidelity and obedience in all his lawful commands; and to enforce this he may correct his servant in a reasonable manner.

In defence of his master, a servant may justify assaulting another; and though death should ensue it is not murder, in case of any unlawful attack upon his master's person or property.

Acts of the servant are, in many instances, deemed acts of the master; for as it is by indulgence of the law that he can delegate the power of acting for him to another, it is just he should answer for such substitute, and that his acts being pursuant to the authority given him, should be deemed the acts of his master. If a servant commit an act of trespass by command or encouragement of his master, the master will be answerable; but in so doing his servant is not excused, as he is bound to obey the master in such things only as are honest and lawful.

If a servant of an innkeeper robs his master's guest, the master is bound to make good the loss. Also, if a waiter at an inn sells a man bad wine, by which his health is impaired an action will be against the master; for his permitting him to sell it to any person is deemed an implied general command. In like manner if a servant is frequently permitted to do a thing by the tacit consent of his master, the master will be liable, as such permission is equivalent to a general command.

If a servant be usually sent upon trust with any tradesman, and he take goods in the name of his master upon his own account, the master must pay for them: and so likewise if he be sent somtimes on trust, and other times with money; for it is not possible for the tradesman to know when he comes by the order of his master, and when by his own authority. But if a man usually deals with his tradesmen himself, or constantly pays them ready money, he is not answerable for what his servant may take up in his name; for in this case there is not, as in the other, any implied order to trust him.

MASTIC, a resinous substance in the form of tears, of a very pale yellow colour, and farinaceous appearance, having little smell, and a bitter astringent taste. It flows naturally from the tree, but its produce is accelerated by incisions. The lesser turpentine tree and the lentiscus afford the mastic of commerce No

volatile oil is obtained from this substance when distilled with water. Pure alcohol and oil of turpentine dissolve it; water scarcely acts upon it; though by mastication it becomes soft and tough, like wax. When chewed a little while, however, it is white, opaque, and brittle, so as not to be softened again by chewing. The part insoluble in alcohol much resembles in its properties caoutchouc. It is used in fumigations, in the composition of varnishes, and is supposed to strengthen the gums.

MASTICATION, in medicine, the action of chewing, or of agitating the solid parts of our food between the teeth, by means of the motion of the jaws, the tongue, and the lips, whereby it is broken into small pieces, impregnated with saliva, and so fitted for deglutition and a more easy digestion.

MASTOIDES. See ANATOMY.

MATCH, a kind of rope slightly twisted, and prepared to retain fire for the uses of artillery, mines, fireworks, &c. It is made of hempen tow, spun on the wheel like cord, but very slack.

MATCH, *quick*, used in artillery, is made of three cotton strands drawn into lengths, and put into a kettle just covered with white-wine vinegar, and then a quantity of saltpetre and mealed powder is put into it, and boiled till well mixed.

MATERIA *Medica*, may be defined to be that branch of the subject of medicine which treats of the particular substances of which medicine in general is composed. The term however has by some been applied not merely to medicine, but to every thing relating to food and drink: but this extension of the application of the term seems to be incorrect; as there is certainly room for a distinction between dietetics, and the cure of diseases. The Materia Medica being so intimately connected with medicine itself, how proper soever it may be to treat of them separately where there is ample scope for it, we presume the generality of our readers will excuse our not giving them a view of the subject which must, from the limits to which our work is confined, be necessarily imperfect. And [illegible] same remark will equally apply to the subject of pharmacy, that proportion of [illegible] page [illegible] for topics of this nature shall be devoted to a brief view of the subject of medicine, which see.

MATHEMATICAL INSTRUMENTS, this term includes all instruments whatever that are used in the practical department of every branch of the mathematics; but is most commonly used to denote those sets of instruments usually sold in cases, and made on a portable plan, so as to fold up into a small space, and to be carried in the pocket without injury to any part. These cases generally contain two pairs of compasses, a sector, plain, and a diagonal scale, a parallel ruler, protractor, black-lead pencil, and drawing-pens; an instrument for making dotted lines; and a pair of bow compasses for describing very small circles. The principal of these requiring description are the scales and sector, of which some notice will be taken under those words.

MATHEMATICS, from μάθησις, originally signified any discipline or learning; but at present denotes that science which teaches or contemplates whatever is capable of being numbered or measured, in so far [illegible] computable or measurable, and accordingly is subdivided into arithmetic, which has number for its object, and geometry, which treats of magnitude.

Mathematics are commonly distinguished into pure and speculative, which consider quantity abstractedly; and mixed, which treat of magnitude as subsisting in material bodies, and consequently are interwoven every where with physical considerations.

Mixed mathematics are very comprehensive; since to them may be referred astronomy, optics, geography, hydrography, hydrostatics, mechanics, fortification, navigation.

MATRASS. See LABORATORY.

MATRICARIA, *feverfew*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; there is no pappus; the calyx hemispherical and imbricated, with the marginal leaflets solid, and something sharp. There are eight species, but the only remarkable one is the parthenium or common feverfew, of which there are varieties with double flowers. This plant has received a most extraordinary character in hysteric and other affections of the nerves, as well as for being a carminative or warm stimulating bitter.

MATRICE, or *matrices*, used by the letter-founders. See TYPE.

MATRIX, or *mother earth*, the stone in which metallic ores are found enveloped.

MATROSSES, are soldiers in the train of artillery, who are next to the gunners, and assist them in loading, firing, and spunging the great guns. They carry firelocks, and march along with the store-waggons.

MATT, in a ship, rope-yarn, junk, &c. beaten flat and interwoven; used in order to preserve the yards from galling or rubbing in hoisting or lowering them.

MATTER, in common language, is a term of similar import with *body*, and denotes that which is tangible, visible, and extended; but among philosophers it signifies that substance of which all bodies are composed; and in this sense it is synonymous with the word *element*.

It must be confessed that there [illegible] much difficulty attendant on the investigation of this subject: and although it has called forth the powers of such men as Newton, Berkley, Priestley, and others, we do not seem to be yet in possession of any satisfactory theory of it. The following remarks, which form part of a paper in Tilloch's Philosophical Magazine for November, 1823, appeared to us so truly appropriate, and indicative of an understanding of the subject so superior to any thing with which we had hitherto met, that we could not resist the temptation to lay them before our readers.

Bulk and extension pre-suppose solid elementary particles, of which forms are compounded; for if there be no such primary solid particles, there can be no material solidity whatever, either primary or derived; thus no material bulk or extension,—which is absurd.

A solid or primary particle of matter must be the smallest particle, and can admit of no divisibility; for if it can be divided into parts, it is not a solid or primary or the smallest particle; matter is not therefore infinitely divisible

That original, elementary, or solid particle of matter, which admits of no further division, must be the smallest particle of matter; and to say that there is no such thing as this smallest particle, is the same as to affirm that there are no material forms at all;—because it is to affirm that a whole can exist without the parts necessary to compose it.

From this it follows, that there is but one elementary principle in matter, of which principle the primary particle above mentioned consists,—and that all material subjects are forms compounded by motion arranging and co-arranging this elementary principle in innumerable relations and modes; for if there be primary material particles, these must be innumerable, in order to their entering into and producing the innumerable forms and combinations of forms observable in the material universe. It is, moreover, in accordance with reason and observation, thus to consider the original substantiality of matter, whence arises our idea of a simple or primary particle of material substance, called an atom; a congregation of which atoms, by modes of motion, furnishes the idea of natural compounds, or material subjects as they exist in nature, in all their varieties; for as it is evident that modes of motion produce changes in material subjects by transforming them into other material subjects of a totally different form and quality, so analogy points to the conclusion,—that all differences in material subjects, as they exist in nature, are effects of motion disposing primary particles into forms, and then operating successive and various combinations of those forms; and thus, that what is called chemical action, is, when considered in its origin, nothing more than an effect of motion in the more refined and subtle order of substances;—decomposition being effected by opposing forces, composition by attractive forces: and thus also, chemical action, like that which is called mechanical, is resolvable into an effect of motion.

The primary particles of matter, or the substances of which the material universe compounded, appear evidently to be passive, and to be operated upon by active substances of a higher order in creation: and that this is the case, may be concluded from observing the various subjects in nature, to the life of which matter may be said to serve as a fixing or ultimate medium, or instrumental basis; for nothing of life appears to belong inherently to the material substances composing those forms or subjects in nature: on the contrary, the material substances composing such forms, seem to contain and to be operated upon by *interior* forms of life, actuating and disposing them, by modes of motion, into outward forms corresponding to such *interior* or inward forms.

Matter, then, considered in itself, is a passive substance, created as an instrument, or *medium*, for the develepement of an active, living, immaterial substance, in the ultimate or lowest degree of existence, namely, in nature; and this by being made the passive subject into which such living and active subject may enter and manifest itself. Would not such a doctrine, if fully developed, satisfactorily explain some of the first principles of the economy of nature, and prove the presence of the invisible in the visible world, and the order of life therein? Under this view, the natural universe is primarily divisible into two *universals* or principals which enter into every particular of which it is constituted; namely, the active, immaterial, or spiritual; and the passive, material, or natural; the latter being created from, and for the use of the former, and being the last result of the Divine Operation.

MATTUSCHKÆA, a genus of the tetrandria monogynia class and order. The calyx is four-parted; corolla one-petalled; germ [illegible]rior, four-cleft. There is one species; a herb of Guiana.

MAURITIA, the *gingko*, or *maiden-hair*, a genus of plants belonging to the natural order of almæ. The calyx of the male is monophyllous; the corolla monopetalous, with six stamina. It is a native of Japan, where it is also known by the names of ginan and itsio. It rises with a long, erect, thick, and branched stem, to the size of a walnut-tree.

MAXILLA. See ANATOMY.

MAXIMUM, in mathematics, denotes the greatest quantity attainable in any given case. If a quantity conceived to be generated by motion, increases or decreases, till it arrives at a certain magnitude or motion, and then, on the contrary, grows less or greater, and it be required to determine the said magnitude or position, the question is called a problem de maximis et minimis.

Thus let a point *m* move uniformly in a right line from A towards B, and let another point *n* move after it, with a velocity either increasing or decreasing, but so that it may, at a certain position D, become equal to that of the former point *m*, moving uniformly.

This being premised, let the motion of *n* be first considered as an increasing one; in which case the distance of *n* behind *m* will continually increase, till the two points arrive at the contemporary positions C and D; but afterwards it will again decrease: for the position of *n* till then being slower than at D, it is also slower than that of the preceding point *m* (by the hypothesis), but becoming quicker afterwards than that of *m*, the distance *m n* (as has already been said) will again decrease; and therefore is a maximum, or the greatest of all, when the celerities of the two points are equal to each other.

But if *n* arrives at D with a decreasing celerity, then its motion being first swifter, and afterwards slower, than that of *m*, the distance *m n* will first decrease and then increase, and therefore is a minimum, or the least of all, in the forementioned circumstance. Since then the distance *m n* is a maximum, or a minimum, when the velocities of *m* and *n* are equal, or when that distance increases as fast through the motion of *m* as it decreases by that of *n*, its fluxion at that instant is evidently equal to nothing. Therefore, as the motion of the points *m* and *n* may be conceived such that their distance *m n* may express the measure of any variable quantity whatever, it follows, that the fluxion of any variable quantity whatever, when a maximum or a minimum, is equal to nothing.

The rule therefore to determine any flowing quantity in an equation proposed, to an extreme value, is: having put the equation into fluxions,

Let the fluxion of that quantity, whose extreme value is sought, to be supposed equal to nothing; by which means all those members of the equation in which it is found will vanish, and the remaining ones will give the determination of the maximum or minimum required.

MEAD, an agreeable liquor made of honey and water.

There are many receipts for making mead, of which the following is one of the best. Take four gallons of water, and as much honey as will make it bear an egg; add to this the rind of three lemons, boil it, and scum it well as it rises. Then take it off the fire, and add three lemons cut in pieces; pour it into a clean tub or open vessel, and let it work for three days; then scum it well, and pour off the clear part into a cask, and let it stand open till it ceases to make a hissing noise; then stop it up close, and in three months' time it will be fine and fit for bottling. If you would give it a finer flavour, take cloves, mace, and nutmeg, of each four drams; beat them small, tie the powder in a piece of cloth, and put it into the cask.

MEADOW. See AGRICUTURE.

MEAN, a middle state between two extremes; as a mean motion, mean distance, arithmetical mean, geometrical mean, &c.

MEAN, *arithmetical* is half the sum of the extremes. So 4 is an arithmetical mean between 2 and 6, or between 3 and 5, or between 1 and 7; also an arithmetical mean between a and b is $\frac{a+b}{2}$, or $\frac{1}{2}a + \frac{1}{2}b$.

MEAN, *geometrical*, commonly called a mean proportional, is the square root of the product of the two extremes; so that, to find a mean proportional between two given extremes, multiply these together, and extract the square root of the product.

MEAN, *harmonical*, is double a fourth proportional to the sum of the extremes, and the two extremes, themselves a and b: thus, as $a + b : a :: 2b \cdot \frac{2ab}{a+b} = m$, the harmonical mean between a and b. Or it is the reciprocal of the arithmetical mean between the reciprocals of the given extremes.

MEASLES. See MEDICINE.

MEASURE signifies any given quantity, estimated as one, to which the proportion of other similar quantities may be expressed.

Measure is classed under a variety of heads, of which the following are illustrations.

MEASURE, in geometry, denotes any quantity assumed as one, or unity, to which the ratio of the other homogeneous or similar quantities is expressed.

MEASURE *of a solid*, is a cubic inch, foot, or yard; in other words, a cube, the side of which is an inch, a foot, or a yard.

MEASURE *of a line*, is the extension of a right line at pleasure, which is to be considered as unity; for instance, an inch, a foot, or a yard.

MEASURE *of a figure*, or a surface perfectly level, thence called a plane surface, is a square inch, foot, or yard. This square is termed the measuring unit, because the side is an inch, a foot, a yard, or any other determinate extent.

MEASURE *of a certain portion or quantity of matter*, is its weight.

MEASURE *of a number*, applies thus: 2 is the measure of 4, 3 of 6, &c.; in fact, it is any number which divides without a remainder.

MEASURES in a legal and commercial sense are various, according to the various kinds and dimensions of the things measured.

Long Measures, or Measures of Application.

1. The English and Scotch standards.

The English lineal standard is the yard, containing 3 English feet, equal to 3 Paris feet, 1 inch, and 3-twelfths of an inch, or 7-ninths of a Paris ell.

The Scots elwand is divided into 37 inches. The Scots inch and foot are larger than the English, in the proportion of 180 to 185. The Scots ell, though forbidden by law, is still used for measuring some coarse commodities, and is the foundation of the land-measure of Scotland.

Itinerary measure is the same both in England and Scotland. The length of the chain is 4 poles, or 22 yards; 80 chains make a mile.

ENGLISH MEASURES.

	Inches.
A foot is	12
A yard	36
A pole, or rod	198
A furlong	7920
A mile	63360
A link	7.92
A chain	792
A nail of cloth	2¼
A quarter	9
A yard	36
An ell	45
A hand	4
	Square yards.
An acre	4840

The wine gallon is fixed at 231 cubic inches by an act passed in the reign of Queen Anne, consequently,

	Cubic inches.
A pint is	28.875
A quart	57.75
A barrel	7276.5
A hogshead	14553.
A pint of country ale, or beer measure, is	35 25
A quart	70.5
A gallon	282.
A barrel, beer measure, is	10152.
——— ale ditto	9024.
——— country do	9588.
A hogshead, beer measure is	15228.
——— ale ditto	13336.
——— country ditto	14382.
A pint, dry measure, is	33.6
A quart	67.2
A pottle	134.4
A gallon	268.8
A peck	537.6
A Winchester bushel	2150.42
A heaped bushel is one-third more.	
A quarter	17203.36

A wey, or load, is five quarters; and two loads make a last of wheat.

Sixty pounds is the mean weight of a bushel of wheat, 50 of barley, and 38 of oats.

Thirty-six heaped bushels make a chaldron of coals, which generally weigh about 2988 pounds.

An inch pipe, ten yards in length, contains precisely an ale gallon, weighing 10⅕ pounds.

The ancient standard wine gallon of Guildhall contains 234 cubic inches.

2. The French standard was formerly the aune or ell, containing 3 Paris feet, 7 inches, 8 lines, or 1 yard 2-sevenths English; the Paris foot royal exceeding the English by 68-thousandth parts. This ell is divided two ways, viz. into halves, thirds, sixths, and twelfths; and into quarters, half-quarters, and sixteenths. The French however have formed an entirely new system of weights and measures according to the following table.

Proportions of the measures of each species to its principal measure or unity.	First part of the name which indicates the proportion to the principal measure or unity.	PRINCIPAL MEASURES OR UNITIES.				
		Length.	Capacity.	Weight.	Agrarian.	For firewood.
10,000 1,000 100 10 0 0.1 0.01 0.001	Myria Kilo Hecto Deca Deci Centi Milli	Metre.	Litre.	Gramme	Arc.	Stere.
Proportion of the principal measures between themselves, and the length of the meridian.		10,000,000th part of the dist. from the pole to the equator.	A decimetre cube.	Weight of a centimetre cube of distilled water.	100 Square metres.	One cubic metre.
Value of the principal measure in the ancient French measures.		3 feet 11 lines and ½ nearly.	1 pint and 1/10, or 1 litron and ¼ nearly.	18 grains and 841,000 parts.	2 square perches des eaux et forêt.	1 demi-voie or ¼ of a cord des eaux et forêt.
Value in English measures.		Inches 39.383.	61.083 inches, which is more than the wine and less than the beer quart.	22.966 grains.	11.968 square yards.	

	English Inches.
Millometre	.03937
Centimetre	.39371
Decimetre	3.93710
Metre	39.37100
Decametre	393.71000
Hecatometre	3937.10000
Chiliometre	39371.00000
Myriometre	393710.00000

The metre is 1.09364 yards, or nearly 1 yard 1⅓ nail, or 443,2959 lines French, or .513074 toises.

A decametre is 10 yards, 1 foot, 9.7 inches.

A hecatometre, 109 yards, 1 foot, 1 inch.

A chiliometre, 4 furlongs, 213 yards, 1 foot 10.2 inches.

A micrometre, 6 miles, 1 furlong, 156 yards, 6 inches.

Eight chiliometres are nearly five miles.

An inch is .0254 metre; 2441 inches, 62 metres; 1000 feet, nearly 305 metres.

An are, a square decametre, is 3.95 perches.

A hecatre, 2 acres, 1 rood, 35.4 perches.

	ches English.
Millilitre	.06103
Centilitre	.61028
Decilitre	6.10280
Litre, a cubic decimitre	61.02800
Decalitre	610.28000
Hecatolitre	6102.80000
Chiliolitre	61028.00000
Myriolitre	610280.00000

Two and one-eighth wine pints are about a litre; 3 wine pints are nearly 14 decilitres; a chiliolitre is one tun, 12.75 wine gallons.

3.5317 cubic feet make a decistere, a measure for firewood.

A stere, a cubic metre, .35.3171. A Paris foot is equal to 12.785 inches.

3. The standard in Holland, Flanders, Sweden, a good part of Germany, many of the Hanse towns, as Dantzic and Hamburgh, and at Geneva, Frankfort, &c. is likewise the ell; but the ell in all these places differs from the Paris ell. In Holland it contains one Paris foot 11 lines, or 4-sevenths of the Paris ell. The Flanders ell contains 2 feet 1 inch, 5 lines, and half a line, or 7-twelfths of the Paris ell. The ell of Germany, Brabant, &c. is equal to that of Flanders

4. The Italian measure is the bracchio, brace, or fathom. This is used in the states of Modena, Venice, Florence, Lucca, Milan, Mantua, Bologna, &c. but is of different lengths. At Venice it contains 1 Paris foot, 11 inches, 3 lines, or 8-fifteenths of the Paris ell. At Bologna, Modena, and Mantua, the brace is the same as at Venice. At Lucca it contains 1 Paris foot, 9 inches, 10 lines, or half a Paris ell. At Florence it contains 1 foot, 9 inches, four lines, or 49-hundredths of a Paris ell. At Milan, the brace for measuring of silks is one Paris foot, 7 inches, 4 lines, or 4-ninths of a Paris ell; that for woollen cloths is the same with the ell of Holland. Lastly, at Bergama the brace is 1 foot, 7 inches, 6 lines, or 5-ninths of a Paris ell. The usual measure at Naples, however, is the canna, containing 6 feet, 10 inches, and 2 lines, or 1 Paris ell and 15-seventeenths.

5. The Spanish measure is the vara or yard, in some places called the barra: containing 17 twenty-fourths of the Paris ell. But the measure in Castile and Valencia is the pan, span, or palm; which is used, together with the canna, at Genoa. In Arragon, the vara is equal to a Paris ell and a half, or 5 feet, 5 inches, 6 lines.

6. The Portuguese measure is the cavedos, containing 2 feet, 11 lines, or four sevenths of a Paris ell; and the vara, 106 whereof make 100 Paris ell.

7. The Piedmontese measure is the ras, containing 1 Paris foot, 9 inches, 10 lines, or half a Paris ell. In Sicily, their measure is the canna, the same with that of Naples.

8. The Muscovite measures are the cubit, equal to 1 Paris foot, 4 inches, 2 lines; and the archin, two whereof are equal to three cubits.

9. The Turkish and Levant measures are the picq. containing 2 feet, 2 inches, and 2 lines, or three-fifths of the Paris ell. The Chinese measure is the cobre. ten whereof are equal to three Paris ells. In Persia, and some parts of the Indies, the gueze, of which there are two kinds; the royal gueze, called also the gueze monkelser, containing 2 Paris feet, 10 inches, 11 lines, or four-fifths of the Paris ell; and the shorter gueze, called simply gueze, only two-thirds of the former. At Goa and Ormuz, the measure is the vara, the same with that of the Portuguese, having been introduced by them. In Pegu, and some other parts of the Indies, the cando, or candi, equal to the ell of Venice. At Goa, and other parts, they use a larger cando, equal to 17 Dutch ells, exceeding that of Babel and Balsora by $\frac{7}{8}$ per centum, and the vara by 6½. In Siam, they use the ken, short of three Paris feet by one inch. The ken contains two soks, the sok two keubs, the kube 12 nious or inches, the niou to be equal to eight grains of rice, *i. e.* to be about nine lines.

English square or superficial measures are raised from the yard of 36 inches multiplied into itself, and thus producing 1296 square inches in the square yard: the divisions of this are square feet and inches; and the multiples, poles, roods, and acres, as in the following table:

Cubical MEASURES *or Measures of capacity for liquids.*—The English measures were originally raised from troy-weight, it being enacted by several statutes that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, should weigh a gallon of wine-measure, the divisions and multiples, of which were to form the other measures: it was also ordered, that there should be but one liquid measure in the kingdom: yet custom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a second standard gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy-weight. From this latter standard are raised two several measures, the one for ale, the other for beer.

MEASURE *for Horses*, is the hand, which, by statute, contains four inches.

MEASURE is also used to signify the cadence and time observed in poetry, dancing, and music, to render them regular and agreeable. See METRE.

MEASURE, in music, the interval or space of time which the person who beats time takes between the rising and falling of his hand, in order to conduct the movement sometimes quicker and sometimes slower, according to music or subject that is to be sung or played.

MECHANICAL, in mathematics, denotes a construction of some problem, by the assistance of instruments, as the duplicature of the cube and quadrature of the circle, in contradistinction to that which is done in an accurate and geometrical manner.

MECHANICAL *curve*, is a curve, according to Des Cartes, which cannot be defined by any

algebraical equation; and so stands contradistinguished from algebraic or geometrical curves.

MECHANICS, this term which is derived from the Greek μηχανη, a *machine*, is commonly used to denote that branch of natural philosophy which treats of the laws of the equilibrium, and motion of solid bodies; of the forces by which bodies may be made to act on one another; and on the means of employing them so as to overcome other forces that are more powerful.

Sir Isaac Newton distinguishes this science into practical and rational mechanics.

Rational mechanics comprehends the whole theory of motion, shews when the powers or forces are given, how to determine the motions that are produced by them; and conversely when the phenomena of the motions are given, how to trace the powers or forces from which they arise.

Practical mechanics treats of what are denominated the mechanical powers, viz. the lever, balance, axis and wheel, pulley, wedge, screw, and the inclined plane.

The importance of these to society is incalculable: every machine whatever is composed of one or more of them, sometimes of several combined together.

In considering this science, it will be necessary at first to take some things for granted, that are not strictly true; and after the theory is established, to make the proper allowances for them.

1. That a small portion of the earth's surface, which is spherical, may be considered as a plane. 2. That all bodies be supposed to descend in lines parallel to each other; for though all bodies really tend to the centre of the earth, yet the distance from which they fall is comparatively so small, that their inclination towards each other is inconsiderable. 3. That all planes be considered as perfectly smooth; levers to be inflexible, and without thickness or weight; cords perfectly pliable; and machines without friction and inertia.

Three things are always to be considered in treating of mechanical engines; the weight to be raised, the power by which it is to be raised, and the instrument or engine by which this is to be effected.

The mechanical powers are generally reckoned six; the lever, the pulley, the wheel and axis, the inclined plane, the wedge and the screw.

These perhaps may be reduced to two; for the pulley and wheel are only assemblages of levers, and the wedge and screw are inclined planes.

The Lever.

The *lever* is the simplest of all machines; and is only a straight bar of iron, wood, or other material, supported on, and moveable round, a prop called the fulcrum.

In the lever there are three circumstances to be principally attended to: 1. The fulcrum, or prop, by which it is supported, or on which it turns as an axis, or centre of motion: 2. The power to raise and support the weight: 3. The resistance or weight to be raised or sustained.

The points of suspension are those points where the weights really act, or from which they hang freely. The power and the weight are always supposed to act at right angles to the lever, except it is otherwise expressed.

The lever is distinguished into three sorts, according to the different situations of the fulcrum or prop, and the power, with respect to each other. 1. When the prop is placed between the power and the weight. 2. When the prop is at one end of the lever, the power at the other, and the weight between them. 3. When the prop is at one end, the weight at the other, and the power applied between them.

The lever of the first kind is principally used for loosening large stones; or to raise great weights to small heights, in order to get ropes under them, or other means of raising them to still greater heights; it is the most common species of lever.

ABC, plate XXXI. fig. 1, is this lever, in which B is the fulcrum, A the end at which the power is applied, and C the end where the weight acts.

To find when an equilibrium will take place between the power and the weight, in this as well as in every other species of lever, it is necessary to recollect that when the momenta, or quantities of force, in two bodies are equal, they will balance each other. Now let us consider when this will take place in the lever. Suppose the lever AB, fig. 2. to be turned on its axis, or fulcrum, so as to come into the situation DC; as the end D is farthest from the centre of motion, and as it has moved through the arch AD in the same time as the end B moved through the arch BC, it is evident that the velocity of AB must have been greater than that of B. But the momenta being the products of the quantities of matter, multiplied into the velocities, the greater the velocity, the less the quantity of matter need be to get the same product. Therefore, as the velocity of A is the greatest, it will require less matter to produce an equilibrium than B.

Let us next see how much more weight B will require than A to balance it. As the radii of circles are in proportion to their circumferences, they are also proportionate to similar parts of them; therefore, as the arches AD, CB, are similar, the radius or arm DE bears the same proportion to EC that the arch AD bears to CB. But the arches AD and CB represent the velocities of the ends of the lever, because they are the spaces which they moved over in the same time; therefore the arms DE and EC may also represent these velocities. It is evident then, that an equilibrium will take place when the length of the arm AE multiplied into the power A, shall equal EB multiplied into the weight B; and consequently, that the shorter EB is, the greater must be the weight B; that is, the power and the weight must be to each other inversely, as their distances from the fulcrum. Thus suppose AE, the distance of the power from the prop, to be 20 inches, and EB, the distance of the weight from the prop, to be eight inches, also the weight to be raised at B to be five pounds, then the power to be applied at A must be two pounds; because the distance of the weight from the fulcrum eight, multiplied into the weight five, makes 40; therefore 20, the distance of the power from the prop, must be multiplied by two to get an equal product, which will produce an equilibrium.

The second kind of lever, when the weight is between the fulcrum and the power, is repre

sented by fig. 3, in which A is the fulcrum, B the weight, and C the power. The advantage gained by this lever, as in the first, is as great as the distance of the power from the prop exceeds the distance of the weight from it. Thus if the point *a*, on which the power acts, is seven times as far from A as the point *b*, on which the weight acts, then one pound applied at C will raise seven pounds at B. To this kind of lever may be reduced oars, rudders of ships, doors turning upon hinges, cutting-knives which are fixed at the point, &c. If in this lever we suppose the power and the weight to change places, so that the power may be between the weight and the prop, it will become a lever of the third kind; in which, that there may be a balance between the power and the weight, the intensity of the power must exceed the intensity of the weight just as much as the distance of the weight from the prop exceeds the distance of the power. Thus let E, fig. 4, be the prop of the lever EF, and W a weight of one pound, placed three times as far from the prop as the power P acts at F, by the cord going over the fixed pulley D: in this case the power must be equal to three pounds, in order to support the weight of one pound.

To this sort of lever are generally referred the bones of a man's arm; for when he lifts a weight by the hand, the muscle that exerts its force to raise that weight is fixed to the bone about one-tenth part as far below the elbow as the hand is. And the elbow being the centre round which the lower part of the arm turns, the muscle must therefore exert a force ten times as great as the weight that is raised.

What is called the hammer-lever differs in nothing but its form, from a lever of the first kind. Its name is derived from its use, that of drawing a nail out of wood by a hammer.

Let A C B fig. 5, represent a lever of this sort, bent at C, which is its prop, or centre of motion. P is a power acting upon the longer arm AC, at A, by means of the cord DA going over the pulley D; and W is a weight or resistance acting upon the end B of the shorter arm CB. If the power is to the weight as CB is to CA, they are in equilibrio; thus, suppose W to be five pounds, acting at the distance of one foot from the centre of motion C, and P to be one pound, acting at A, five feet from the centre C; the power and weight will just balance each other.

If several levers are combined together in such a manner, as that a weight being appended to the first lever may be supported by a power applied to the last, as in fig 6, (which consists of three levers of the first kind, and is so contrived, that a power applied at the point L, of the lever C, may sustain a weight at the point S of the lever A,) the power must here be to the weight; in a ratio, or proportion, compounded of the several ratios, which those powers that can sustain the weight by the help of each lever, when used singly and apart from the rest, have to the weight. For instance: if the power which can sustain the weight P by the help of the lever A, is to the weight as 1 to 5; and if the power which can sustain the same weight by the lever B alone, is to the weight as 1 to 4; and if the power which could sustain the same weight by the lever C is to the weight as 1 to 5; then the power which will sustain the weight by the help of the three levers joined together, will be to the weight in a proportion consisting of the several proportions multiplied together, of 1 to 5, 1 to 4, and 1 to 5; that is of 1 to 100. For since, in the lever A, a power equal to one-fifth of the weight P pressing down the lever at L, is sufficient to balance the weight; and since it is the same thing whether that power is applied to the lever A at L, or the lever B at S, the point S bearing on the point L; a power equal to one-fifth of the weight P, being applied to the point S of the lever B, will support the weight; but one-fourth of the same power being applied to the point L of the lever B, and pushing the same upward, will as effectually depress the point S of the same lever, as if the whole power was applied at S; consequently, a power equal to one-fourth of one-fifth, that is, one-twentieth of the weight P, being applied to the point L of the lever B, and pushing up the same, will support the weight; in like manner, it matters not whether that force is applied to the point L of the lever B, or to the point S of the lever C, since, if S be raised, L, which rests on it, must be raised also; but one-fifth of the power applied at the point L of the lever C, and pressing it downwards, will as effectually raise the point S of the same lever, as if the whole power were applied at S, and pushed up the same; consequently a power equal to one-fifth of one-twentieth, that is, one-hundredth part of the weight P, being applied to the point L of the lever C, will balance the weight at the point S of the lever A.

The balance, an instrument of very extensive use in comparing the weights of bodies, is a lever of the first kind, whose arms are of equal length. The points from which the weights are suspended being equally distant from the centre of motion, will move with equal velocity; consequently, if equal weights are applied, the momenta will be equal, and the balance will remain in equilibrio.

In order to have a balance as perfect as possible, it is necessary to attend to the following circumstances: 1. The arms of the beam ought to be exactly equal, both as to weight and length. 2. The points from which the scales are suspended should be in a right line, passing through the centre of gravity of the beam; for by this the weights will act directly against each other, and no part of either will be lost on account of any oblique direction. 3. In a balance, therefore, the fulcrum ought always to be placed a little above the centre of gravity. Its vibrations will be quicker, and its horizontal tendency stronger, the lower the centre of gravity, and the less the weight upon the points of suspension. 4. The friction of the beam upon the axis ought to be as little as possible; because should the friction be great, it will require a considerable force to overcome it. The axis of motion should be formed with an edge like a knife and made very hard; these edges are at first made sharp, and then rounded with a fine hone, or piece of buff leather, which causes a sufficient bluntness, or rolling edge. 5. The pivots which form the axis or fulcrum, should be in a straight line, and at right angles to the beam. 6. The arms should be as long as possible, relatively to their thickness, and the purposes for which they are intended; as the longer they are, the

more sensible is the balance. They should also be made as stiff and inflexible as possible; for if the beam is too weak, it will bend, and become untrue. 7. The rings, or the piece on which the axis bears, should be hard and well polished, parallel to each other, and of an oval form, that the axis may always keep its proper bearing, or remain always at the lowest point.

The statera, or Roman steel-yard, is a lever of the first kind, and is used for finding the weights of different bodies, by one single weight placed at different distances from the prop or centre of motion D fig. 7. For the shorter arm DG is of such a weight as exactly to counterpoise the longer arm DX. If this arm is divided into as many equal parts as it will contain, each equal to GD, the single weight P (which we may suppose to be one pound) will serve for weighing any thing as heavy as itself, or as many times heavier as there are divisions in the arm DX, or any quantity between its own weight and that quantity. As for example, if P is one pound and placed at the first division I in the arm DX, it will balance one pound in the scale at W: if it is removed to the second division at 2, it will balance two pounds in the scale; if to the third, three pounds; and so on to the end of the arm DX. If any of these integral divisions be subdivided into as many equal parts as a pound contains ounces, and the weight P be placed at any of these subdivisions, so as to counterpoise what is in the scale, the pounds and odd ounces therein will by that means be ascertained.

The Wheel and Axle.

The wheel and axle is a machine much used, and is made in a variety of forms. It consists of a wheel with an axle fixed to it, so as to turn round with it; the power being applied at the circumference of the wheel, and the weight to be raised is fastened to a rope which coils round the axle.

AB, fig. 9, is a wheel and CD an axle fixed to it, and which moves round with it. If the rope which goes round the wheel is pulled, and the wheel turned once round, it is evident that as much rope will be drawn off as the circumference of the wheel; but while the wheel turns once round, the axle turns once round; and consequently the rope by which the weight is suspended, will wind once round the axis, and the weight will be raised through a space equal to the circumference of the axis.

The velocity of the power, therefore, will be to that of the weight, as the circumference of the wheel to that of the axis.

That the power and the weight may be in equilibrio, therefore, the power must be to the weight as the circumference of the wheel to that of the axis.

It is proved by geometry that the circumferences of different circles bear the same proportion to each other as their respective diameters do; consequently the power is to the weight, as the diameter also of the axis to that of the wheel.

Thus, suppose the diameter of the wheel to be eight inches, and the diameter of the axis to be one inch; then one ounce acting as the power P will balance eight ounces as a weight W; and a small additional force will cause the wheel to turn with its axis, and raise the weight; and for every inch which the weight rises, the power will fall eight inches.

The wheel and axis may be considered as a kind of perpetual lever, of which the fulcrum is the centre of the axis, and the long and short arms are the diameter of the wheel and the diameter of the axis. See fig. 10.

From this it is evident, that the larger the wheel, and the smaller the axis, the stronger is the power of this machine; but then the weight must rise slower in proportion.

A capstan is a cylinder of wood, with holes in it, into which are put bars, or levers, to turn it round; these are like the spokes of a wheel without the rim. Sometimes the axis is turned by a winch fastened to it, which in this respect serves for a wheel; and is more powerful in proportion to the largeness of the circle it describes, compared with the diameter of the axle.

When the parts of the axis differ in thickness, and weights are suspended at the different parts, they may be sustained by one and the same power applied to the circumference of the wheel: provided the product arising from the multiplication of the power into the diameter of the wheel, is equal to the sum of the products arising from the multiplication of the several weights into the diameters of those parts of the axis from which they are suspended.

In considering the theory of the wheel and axle, we have supposed the rope that goes round the axle to have no sensible thickness; but as in practice this cannot be the case, if it is a thick rope, or if there are several folds of it round the axis, you must measure to the middle of the outside rope, to obtain the diameter of the axis, for the distance of the weight from the centre is increased by the coiling up of the rope.

If teeth are cut in the circumference of a wheel, and if they work in the teeth of another wheel of the same size, as fig. 11, it is evident that both the wheels will revolve in the same time; and the weight appended to the axle of the wheel B, will be raised in the same time as if the axle had been fixed to the wheel A. But if the teeth of the second wheel are made to work in teeth made in the axle of the first, as at fig. 12, as every part of the circumference of the second wheel is applied successively to the circumference of the axle of the first, and as the former is much greater than the latter, it is evident that the first wheel must go round as many times more than the second, as the circumference of the second wheel exceeds that of the first axle.

In order to a balance here, the power must be to the weight, as the product of the circumferences, or diameters of the two axles multiplied together, is to the circumferences or diameters of the two wheels. This will become sufficiently clear, if it is considered as a compound lever, which was explained above. Instead of a combination of two wheels, three or four wheels may work in each other, or any number; and by thus increasing the number of wheels, or by proportioning the wheels to the axis, any degree of power may be acquired.

To this sort of engine belong all cranes for raising great weights, and in this case the wheel may have cogs all round it, instead of handles; and a small trundle may be made to

work in the cogs, and be turned by a winch, which will make the power of the engine to exceed the power of the man who works it, as much as the number of revolutions of the winch exceeds those of the axle CD, fig. 9, when multiplied by the excess of the length of the winch above the length of the semidiameter of the axle, added to the semidiameter of the rope K, by which the weight is drawn up. Thus, suppose the diameter of the rope and axle taken together to be 13 inches, and consequently half their diameter to be 6½ inches, so that the weight W will hang at 6½ inches perpendicular distance from below the centre of the axle. Now let us suppose the wheel AB, which is fixed on the axle, to have 80 cogs, and to be turned by means of a winch 6½ inches long, fixed on the axle of a trundle of eight staves, or rounds, working in the cogs of the wheel; here it is plain, that the winch and trundle would make ten revolutions for one of the wheel AB, and its axis CD, on which the rope K winds in raising the weight W: and the winch being no longer than the sum of the semidiameters of the great axle and rope, the trundle could have no more power on the wheel than a man could have by pulling it round by the edge, because the winch would have no greater velocity than the edge of the wheel has, which we here suppose to be ten times as great as the velocity of the rising weight: so that, in this case, the power gained will be as 10 is to 1. But if the length of the winch is 13 inches, the power gained will be as 20 to 1; if 19½ inches (which is long enough for any man to work by,) the power gained will be as 30 to 1; that is, a man could raise 30 times as much by such an engine, as he could do by his natural strength without it, because the velocity of the handle of the winch would be 30 times as great as the velocity of the rising weight; the absolute force of any engine being in the proportion of the velocity of the power, to the velocity of the weight raised by it. But then, just as much power or advantage as is gained by the engine, so much time is lost in working it, which is common in all mechanical cases whatever.

In this sort of machines, it is requisite to have a ratchet wheel on the end of the axle C, with a catch to fall into its teeth; which will at any time support the weight, and keep it from descending, if the person who turns the handle should quit his hold while the weight is rising. By this means, the danger is prevented which might otherwise happen by the running down of the weight when left at liberty.

The Pulley.

The *pulley* is a small wheel turning on an axis, with a drawing-rope passing over it: the small wheel is usually called a sheeve, and is so fixed in a box, or block, as to be moveable round a pin passing through its centre.

Pulleys are of two kinds:—1. Fixed, which do not move out of their places; 2. Moveable, which rise and fall with the weight.

When a pulley is fixed, as fig. 13, two equal weights suspended to the ends of a rope passing over it, will balance each other; for they stretch the rope equally, and if either of them is pulled down through any given space, the other will rise through an equal space in the same time; and consequently, as the velocities of both are equal, they must balance each other. This kind of pulley, therefore, gives no mechanical advantage; so that you can raise no greater weight by it than you could do by your natural strength. Its use consists in changing the direction of the power, and sometimes enabling it to be applied with more convenience. By it a man may raise a weight to any point, without moving from the place he is in; whereas, otherwise, he would have been obliged to ascend with the weight: it also enables several men together to apply their strength to the weight by means of the rope.

The moveable pulley represented at A, fig. 14, plate XXXII. is fixed to the weight W, and rises and falls with it. In comparing this to a lever, the fulcrum must be considered as at A; the weight acts upon the centre, and the power is applied at the extremity of the lever D. The power, therefore, being twice as far from the fulcrum as the weight is, the proportion between the power and weight, in order to balance each other, must be as 1 to 2. Whence it appears, that the use of this pulley doubles the power, and that a man may raise twice as much by it as by his strength alone. Or it may be considered in this way. Every moveable pulley hangs by two ropes equally stretched, and which must, consequently, bear equal parts of the weight: but the rope AB being made fast at B, half the weight is sustained by it; and the other part of the rope, to which the power is applied, has but half the weight to support: consequently the advantage gained by this pulley is as 2 to 1.

When the upper and fixed block contains two pulleys, which only turn upon their axis, and the lower moveable block contains also two, which not only turn on their axis, but rise with the weight F, fig. 15, the advantage gained is as 4 to 1. For each lower pulley will be acted upon by an equal part of the weight; and because in each pulley that moves with the weight, a double increase of power is gained, the force by which F may be sustained, will be equal to half the weight divided by the number of lower pulleys; that is, as twice the number of lower pulleys is to 1, so is the weight suspended to the power.

But if the extremity C fig. 16, is fixed to the lower block, it will sustain half as much as a pulley; consequently here the rule will be, as twice the number of pulleys adding unity is to one, so is the weight to the power.

These rules hold good, whatever may be the number of pulleys in the blocks.

If, instead of one rope going round all the pulleys, the rope belonging to each pulley is made fast at the top, as in fig. 17, a different proportion between the power and the weight will take place. Here it is evident, that each pulley doubles the power; thus, if there are two pulleys, the power will sustain four times the weight.

Fig. 8 is the concentric pulley, invented by Mr. James White. O, R, are two brass blocks, in which grooves are cut; and round these a cord is passed, by which means they answer the purpose of so many distinct pulleys. The advantage gained is found by doubling the number of grooves in the lower block.

It is common to place all the pulleys in each block on the same pin, by the side of each other, as in fig. 18; but the advantage, and

rule for the power, are the same here as in figs. 15 and 16.

A pair of blocks with the rope fastened round it, is commonly called a tackle.

The Inclined Plane.

This mechanical power is of very great use in rolling up heavy bodies, such as casks, wheelbarrows, &c. It is formed by placing boards or earth in a sloping direction.

The force with which a body descends upon an inclined plane, is to the force of its absolute gravity, by which it would descend perpendicularly in free space, as the height of the plane is to its length. For suppose the plane AB, fig. 19, to be parallel to the horizon, the cylinder C will keep at rest on any part of the plane where it is laid. If the plane is placed perpendicularly, as AB, fig. 20, the cylinder C will descend with its whole force of gravity, because the plane contributes nothing to its support or hindrance; and therefore it would require a power equal to its whole weight to keep it from descending.

Let AB, fig. 21, be a plane parallel to the horizon, and AD a plane inclined to it; and suppose the whole length AD to be three times as great as the perpendicular DB. In this case, the cylinder E will be supported upon the plane DA, and kept from rolling, by a power equal to a third part of the weight of the cylinder; therefore a weight may be rolled up this inclined plane by a third part of the power which would be sufficient to draw it up by the side of an upright wall. It must also be evident, that the less the angle of elevation, or the gentler the ascent is, the greater will be the weight which a given power can draw up; for the steeper the inclined plane is, the less does it support of the weight; and the greater the tendency which the weight has to roll, consequently the more difficult for the power to support it: the advantage gained by this mechanical power, therefore, is as great as its length exceeds its perpendicular height. To the inclined plane may be reduced all hatchets, chisels, and other edge-tools.

The Wedge

Is the fifth mechanical power or machine; it may be considered as two equally inclined planes, joined together at their bases: then DG, fig. 22, is the whole thickness of the wedge at its back ABGD, where the power is applied; EF is the depth or height of the wedge; BF the length of one of its sides; and OF is its sharp edge, which is entered into the wood intended to be split, by the force of a hammer or mallet striking perpendicularly on its back. Thus AB, fig. 23, is a wedge driven into the cleft CED of the wood FG.

When the wood does not cleave at any distance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge, when the power is to the resistance as half the thickness of the wedge at its back is to the length of either of its sides; because the resistance then acts in a direction perpendicular to the sides of the wedge. But when the resistance on each side acts parallel to the back, the power that balances the resistances on both sides will be, as the length of the whole back of the wedge is to double its perpendicular height.

When the wood cleaves at any distance before the wedge (as it generally does,) the power impelling the wedge will not be to the resistance of the wood as the length on the back of the wedge is to the length of both its sides, but as half the length of the back is to the length of either side of the cleft, estimated from the top or acting part of the wedge. For, if we suppose the wedge to be lengthened down from the top CE, to the bottom of the cleft at D, the same proportion will hold; namely, that the power will be to the resistance as half the length of the back of the wedge is to the length of either of its sides: or, which amounts to the same thing, as the whole length of the back is to the length of both the sides. The wedge is a very great mechanical power, since not only wood, but even rocks, can be split by it; which it would be impossible to effect by the lever, wheel and axle, or pulley; for the force of the blow or stroke, shakes the coherent parts, and thereby makes them separate more easily.

The Screw.

The screw, fig. 24, is the sixth and last mechanical power, but cannot properly be called a simple machine, because it is never used without the application of a lever or winch to assist in turning it; and then it becomes a compound engine of a very great force, either in pressing the parts of bodies closer together or in raising great weights. It may be conceived to be made by cutting a piece of paper, ABC, fig. 25, into the form of an inclined plane, or half wedge; and then wrapping it round a cylinder, fig. 26, the edge of the paper AC will form a spiral line round the cylinder, which will give the thread of the screw. It being evident that the winch must turn the cylinder once round, before the weight of resistance can be moved from one spiral winding to another, therefore, as much as the circumference of a circle described by the handle of the winch is greater than the interval or distance between the spirals, so much is the force of the screw. Thus supposing the distance of the spirals to be half an inch, and the length of the winch twelve inches, the circle described by the handle of the winch where the power acts will be 76 inches nearly, or about 152 half-inches, and consequently 152 times as great as the distance between the spirals: and therefore a power at the handle, the intensity of which is equal to no more than a single pound, will balance 152 pounds acting against the screw; and as much additional force as is sufficient to overcome the friction, will raise the 152 pounds; and the velocity of the power will be to the velocity of the weight, as 152 to 1. Hence it appears, that the longer the winch is, and the nearer the spirals are to one another, so much the greater the force of the screw.

A machine for shewing the force or power of the screw may be contrived in the following manner: Let the wheel C have a screw, fig. 24, on its axis, working in the teeth of the wheel D, which suppose to be 48 in number. It is plain, that for every time the wheel C and screw are turned round by the winch A, the wheel D will be moved one tooth by the screw; and therefore, in 48 revolutions of the winch,

the wheel D will be turned once round. Then, if the circumference of a circle, described by the handle of the winch A, be equal to the circumference of a groove round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Consequently, if a line G go round the groove, and have a weight of 48 pounds hung to it, a power equal to 1 pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then if a weight H, of 1 pound be suspended by a line going round the groove of the wheel C, it will balance a weight of 48 pounds hanging by the line G; and a small addition to the weight H will cause it do descend, and so raise up the other weight.

If a line G, instead of going round the groove of the wheel D, go round its axle I, the power of the machine will be as much increased as the circumference of the groove exceeds the circumference of the axle; which supposing to be six times, then one pound at H will balance six times 48, or 288 pounds, hung to the line on the axle; and hence the power or advantage of this machine will be as 288 to 1. That is, a man who by his natural strength could lift a hundred weight, will be able to raise 288 cwts. by this engine. If a system of pulleys were applied to the cord H, the power would be increased to an amazing degree. When a screw acts in a wheel in this manner, it is called an endless screw. When it is not employed in turning a wheel, it consists of two parts: the first is called the male or outside screw; being cut in such a manner, as to have a prominent part going round the cylinder in a spiral manner, which prominent part is called the thread of the screw, the other part which is called the female, or inside screw, is a solid body, containing a hollow cylinder, whose concave surface is cut in the same manner as the convex surface of the male screw, so that the prominent parts of the one may fit the concave parts of the other.

A very considerable degree of friction always acts against the power in a screw; but this is fully compensated by other advantages; for on this account the screw continues to sustain a weight, even after the power is removed, or ceases to act, and presses upon the body against which it is driven. Hence the screw will sustain very great weights; insomuch that several screws, properly applied, would support a large building, whilst the foundation was mending, or renewed.

Of Compound Machines.

Though it is evident from the principles delivered above, that any one of the mechanical powers is capable of overcoming the greatest possible resistance in theory; yet in practice, if used singly for producing very great effects, they would be frequently so unwieldy and unmanageable, as to render it impossible to apply them. For this reason, it is generally found more advantageous to combine them together; by which means the power is more easily applied, and many other advantages are obtained. In all machines, simple as well as compound, what is gained in power is lost in time. Suppose that a man, by a fixed pulley, raises a beam to the top of a house in two minutes, it is clear that he will be able to raise six beams in twelve minutes, but by means of a tackle with three lower pullies he will raise all at once, with the same ease as he before raised one; but then he will be six times as long about it, that is, twelve minutes: thus the work is performed in the same time, whether the mechanical power is used or not. But the convenience gained by the power is very great; for if the six beams are joined in one, they may be raised by the tackle, though it would be impossible to move them by the unassisted strength of one man.

No real gain of force is, therefore, obtained by mechanical contrivances; on the contrary, from friction, and other causes, force is always lost; but by machines we are able to give a more convenient direction to the moving power, and to apply its action at some distance from the body to be moved, which is a circumstance of great importance. By machines also, we can so modify the energy of the moving power, as to obtain effects which it could not produce without this modification.

In machines composed of several of the mechanical powers, the power will be to the weight, when they are in equilibrio, in a proportion formed by the multiplication of the several proportions which the power bears to the weight in every separate mechanical power of which the machine consists.

In contriving machines, simplicity ought particularly to be attended to; for a complicated machine is not only more expensive, and more apt to be out of order, but there is also a greater degree of friction, in proportion to the number of rubbing parts.

Whatever may be the construction of a machine, its power will always be in proportion to the velocity of the power to the weight; and so that this is obtained in the greatest degree that circumstances will admit, then the fewer parts the better.

It is evident, from the principles already laid down, that the velocity of a wheel is to that of a pinion, or smaller wheel which is driven by it, in proportion to the diameter, circumference or number of teeth in the pinion to that of the wheel.

Hence, if you have any number of wheels acting on so many pinions, you must divide the product of the teeth in the wheels by those in the pinions; and the quotient will give the number of turns of the last pinion in one turn of the first wheel. Thus, if a wheel A, fig. 27, of 48, acts on a pinion B of 8, on whose axis there is a wheel C of 40, driving a pinion D of 6, carrying a wheel E of 36, which moves a pinion F of 6, carrying an index; then the number of turns made by the index will be found in this manner: $\frac{48}{8}\times\frac{40}{6}\times\frac{36}{6}=\frac{60120}{288}=240$, the number of turns which the index will make while the wheel A goes once round.

Any number of teeth on the wheels and pinions having the same ratio, will give the same number of revolutions to an axis: thus, $\frac{64}{10}\times\frac{50}{8}\times\frac{36}{6}=\frac{115200}{480}=240$, as before. It therefore depends upon the skill of the engineer or mechanic, to determine what numbers will best suit his design.

It is evident, that the same motion may be performed, either by one wheel and pinion, or

by many wheels and pinions, provided the number of turns of all the wheels bear the same proportion to all the pinions which that one wheel bears to its pinion.

When a wheel is moved immediately by the power, it is called a leader; and if there is another wheel on the same axis, it is called the follower. Thus A, being moved immediately by the power, is to be considered as a leader, and B as a follower: the wheel C being driven by B, becomes a leader, and D a follower; E, fig. 28, is a leader, and the cylinder F may be considered as a follower.

Sometimes the same wheel acts both as a leader and a follower, as in fig. 29, where B is moved by A, and consequently is a follower, while, as it drives C, it is also a leader. Therefore, as to multiply both the divisors and dividend by the same number does not alter the quotient; in mechanical calculations, every wheel, that is both a leader and a follower, may be entirely omitted.

The power of a machine is not at all altered by the size of the wheels, provided the proportions to each other are the same.

The application of animal strength as a moving power in machinery.

A horse draws with the greatest advantage, when the line of draught is not level with his breast, but inclines upwards, making a small angle with the horizontal plane.

A horse drawing weight over a single pulley, can draw 200lb. for eight hours a day, and walking at the rate of 2½ miles in an hour, which is about 3½ feet in a second, and if the same horse be made to draw 240lb. he can work but six hours a day, and cannot go quite so fast.

When a horse draws in a mill, or gin of any kind, great care should be taken that the horse-walk or circle in which he moves, be large enough in diameter, otherwise the horse cannot exert all his strength; for, in a small circle, the tangent (in which the horse draws) deviates more from the circle in which the horse is obliged to go, than in a larger circle. The horse-walk should not be less than 40 feet in diameter, when there is room for it. In a walk of 19 feet diameter, it has been calculated that a horse loses two-fifths of his strength. The worst way of applying the force of a horse, is to make him carry or draw up hill; for if the hill is steep, three men will do more than a horse. As a horse, from the structure of his body, can exert most strength in drawing almost horizontally in a straight line, a man exerts the least strength that way.

A man turning a horizontal windlass by a handle, or winch, should not have above 30lb. weight acting against him, if he is to work ten hours a day, and raise the weight at the rate of three feet and a half in a second. This supposes, however, that the semidiameter of the windlass is equal to the distance from the centre to the elbow of the handle; for if there is a mechanical advantage, as there usually is, by having the diameter of the axle, on which the rope winds, four or five times less than the diameter of the circle described by the hand, then may the weight (taking in also the resistance, on account of the friction and stiffness of the rope, be four or five times greater than 30lb that is, so much as it rises slower than the hand moves.

MEDAL, denotes a piece of metal in the form of coin, such as was either current money among the ancients, or struck on any particular occasion to preserve the portrait of some great person, or the memory of some illustrious action, to posterity.

As historical documents, medals form the principal evidence we can have of the veracity of old historians. In some few instances they correct the names of sovereigns; and in a great many, illustrate the chronology of reigns. By their assistance, the geographer has sometimes been enabled to determine the situation of a town whose name alone has reached us. To the naturalist they afford the only proofs of the knowledge which the ancients had of certain plants and animals; and they sometimes preserve delineations of buildings for the architect, of which not even a ruin is, at this day, standing. To the connoisseur they are absolutely necessary, as they enable him to appropriate the busts and portraits of antiquity. And the scholar need hardly be reminded that they have contributed in no small degree to the elucidation of obscure passages in ancient authors. The alto-relievo of the Greek coins is one of the best schools of study for the sculptor.

The study of medals, perhaps, is not of very ancient date Petrarch is said to have been one of the first who began to study the medallic science. Alphonso, king of Arragon, formed another collection. And a third was placed by Cosmo de Medici among the curiosities in the Museum at Florence. In this country, though we know of the existence of no cabinet before the time of Camden, it may be supposed that the knowledge of coins and medals was introduced from Italy. The "Britannia" was the first work in which engravings of them were produced: and Speed's Chronicle, which soon followed it, was illustrated with coins from the collection of Sir Robert Cotton. Henry prince of Wales was one of the first who had a *rich* cabinet; and he bequeathed it at his death to Charles. The most considerable of our other early collectors were, archbishop Laud, Lord Arundel, and Mr. Selden. Oliver Cromwell, we are told, had a small collection; and the cabinet of Charles the Second is mentioned by Vaillant.

MEDALLION, or MEDALION a medal of an extraordinary size, supposed to be anciently struck by the emperors for their friends, and for foreign princes and ambassadors; but that the smallness of their number might endanger the loss of the devices they bore, the Romans generally took care to stamp the subject of them upon their ordinary coins. Medallions, in respect of the other coins, were the same as modern medals in respect of modern money; they were exempted from all commerce, and had no other value but what was set upon them by the fancy of the owner.

MEDEOLA, *climbing African asparagus*, a genus of the hexandria trigynia order and class of plants. Natural order, sarmentaceæ. No calyx; cor. sexpartite and revoluted; berry trispermous. The flower has no empalement, three-horned germina terminate the style; and

turn to a roundish trifid berry, with three cells. There are three species.

MEDICAGO, *snail-trefoil*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. There are 11 species, though only five are commonly cultivated in this country. The M. sativa or lucern, has been laterly much recommended as a green fodder for cattle, and has been cultivated by some farmers with success.

MEDICINE, is the art of preserving health, and of curing or alleviating disease. It is the same science in its application to animal, as agriculture to vegetable life. In order to reduce the practice of medicine to something definite, to simplify what was perplexed, and to lay down certain general rules for a more accurate investigation of diseases, physicians in all ages have attempted to arrange these last into a systematized form; and the works which have thus treated of diseases, are entitled Nosologies.

The following are the classes, orders, and genera of Cullen, with the exception of the class locales, which relates to those disorders principally that come under the head of surgery.

Table of Classification.

Class I. Pyrexiæ. A frequent pulse, succeeding to shivering or horror; increased heat; disturbed functions; prostration of strength.

Order I. *Febris.* Pyrexia, independant of local affection as its cause; languor, lassitude, and other signs of debility.

Sect. 1. *Intermittentes.* Fevers arising from the miasma of marshy grounds, with an evident remission, the returning fits being almost always ushered in by horror or trembling. One paroxysm only in the day.

Genera. Tertiana; quartana; quotidiana.

Sect. 2. *Continuæ.* Fevers without intermission, not occasioned by marsh miasma, attended with exacerbations and remissions, though not very perceptible.

Genera. Synocha; typhus; synochus.

Order II. *Phlegmasiæ.* Fever, accompanied by local inflammation or topical pain, lesion, or disturbance of the internal functions; sizy blood.

Genera. Phlogasis ophthalmia; phrenitis; cynanche; pneumonia carditis; peritonitis; gastritis; enteritis; hepatitis; splenitis; nephritis; cystitis; hysteritis; rheumatismus; odontalgia podagra; arthropuosis.

Order III. *Exanthemata.* Contagious diseases, which only affect once during life, commencing with fever, and succeeded by phlogosis or inflammatory eruptions on the skin.

Genera. Erysipelas; pestis; variola; varicella; rubeola muliaria; scarlatina; urticaria; pemphygus; apthæ.

Order IV. *Hemorrhagiæ.* Pyrexia; spontaneous discharge of blood; blood when drawn from a vein of a sizy appearance.

Genera. Epistasis; hemaptisis; hæmarrhois; menarrhagia.

Order V. *Profluviæ.* Pyrexia; inordinate discharge, but not of blood.

Genera. Catarrh; dysenteria

Class II. Neuroses. A lesion of sense and motion, without idiopathic pyrexia or local disorder.

Order I. *Comata.* A diminution of voluntary motion with sleep, or a deprivation of sense.

Genera. Apoplexia; paralysis.

Order II. *Adynamiæ.* Diminished voluntary motion, whether vital or natural.

Genera. Syncope; dyspepsia; hypochondriasis; chlorosis.

Order III. *Spasmi.* Irregular action of the muscular fibre.

Sect. 1. In the animal functions.

Genera. Tetanus; trismus; chorea; raphania; epilepsia.

Sect. 2. In the vital functions.

Genera. Palpitatio; asthma; dyspnæ; pertussis.

Sect. 3. In the natural functions.

Genera. Pyrosis; colica; cholera; diarrhœa; diabetes; hysteria: hydrophobia.

Order VI. *Vesaniæ.* Derangement of judgment, independantly of pyrexia or coma.

Genera. Amextia, melancholia; mania oneirodynia.

Class III. Cachexiæ. A depraved habit of body, without idopathic pyrexia or neurosis.

Order I. *Macores.* A wasting of the whole body.

Genera. Tabes; atrophia.

Order II. *Intumescentiæ.* A swelling of the whole or of the greatest part of the body.

Sect. I. *Adiposæ.* Fatty swellings.

Genus. Polysarcia.

Sect. 2. *Flatulosæ.* Windy swellings.

Genera. Pneumatosis; tympanites; physometra.

Sect. 3. *Hyaropes.* Watery swellings.

Anasarca; hydrocephalus; hydrorachiti hydrothorax; arcites; hydrometra; hydrocele physconia.

Order III. *Impetigines.* Cachexies, chiefly deforming the skin and external parts of the body.

Genera. Scrophula; syphilis; scorbutus elephantiasis; lepra; framneesia; trichoma, icterus.

Class I. Order I.—*Febris.*

Of the Phenomena of Fever.

The person is affected with languor or sense of debility, a sluggishness in motion, and some uneasiness in exerting it, with frequent yawning and stretching. At the same time the face and extremities become pale, the features shrink, the bulk of every external part is diminished, and the skin over the whole body appears constricted as if cold had been applied to it. At the coming on of these symptoms, some coldness of the extremities, though little taken notice of by the patient, may be perceived by another person. At length the patient himself feels a sensation of cold, commonly first in his back, but then passing over his whole body; and now his skin feels warm to another person. The patient's sense of cold increasing, produces a tremor in all his limbs, with frequent successions or rigors in the trunk of the body. When this sense of cold and its effects have continued for some time, they become less

violent, and are alternated with warm flushings. By degrees the cold goes off entirely; and a heat greater than natural prevails and continues over the whole body. With this heat the colour of the skin returns, and a preternatural redness appears especially in the face. Whilst the heat and redness come on, the skin is relaxed and smooth, but for some time continues dry. The features of the face and other parts of the body, recover their usual size, and become even more turgid. When the heat, redness, and turgescence, have increased and continued for some time, a moisture appears on the forehead, and by degrees becomes a sweat, which gradually extends downwards over the whole body. As this sweat continues to flow, the heat of the body abates; the sweat after continuing for some time, gradually ceases, the body returns to its usual temperature, and most of the functions are restored to their ordinary state.

This order is divided into two sections, an intermittent, including tertians, quartans, and quotidians, with the different varieties of these distinct genera; and continued, which include the genera of synocha, or simple inflammatory fever; typhus, putrid, or gaol fever; and synochus, a mixed fever commencing like the first, and terminating like the second. The intermittent family are divided as follows: Fevers arising from the miasm of marshy grounds with an evident remission, the returning fits being almost always ushered in by horror or trembling. One paroxysm only in the day. The continued family are defined thus: fevers without intermission, not occasioned by marsh miasm, attended with exacerbations and remissions, though not very perceptible.

The genera of continued fever, are,

1. *Synocha.* "Great heat, pulse frequent, strong, and hard; high-coloured urine, the functions of the sensorium not much impaired." Such character, however, does not answer to any case of simple fever; it is the definition of what Dr. Brown calls the sthenic, which is opposed to the true febrile state.

2. *Typhus.* "A contagious disease, the heat not much increased, pulse frequent, small and weak; urine little changed, sense much impaired, and the strength greatly diminished."

3. *Synochus.* This is made by Cullen a kind of intermediate disease between synocha and typhus.

Exciting causes of fever. On this subject the most opposite opinions prevail. It is imagined by some, that no case of genuine fever, beyond those ephemeral irritations which are of daily occurrence, can possibly originate without the previous application, either through the medium of the lungs, or the surface of the body, of a certain something generated in the system of another individual in the course of the same disease. Others infer, from the daily observation of febrile diseases where no communication with the sick can be traced or suspected, that although the febrifacient matter just spoken of be in many, it is not in all instances the cause of fever; that cold, damp, heat, putrid exhalations whether animal or vegetable, insufficient ventilation, the depressing passions, &c. are all, either singly or in conjunction, capable, under some circumstances, not merely of predisposing to, but of actually engendering, proper fever. Lastly, there are some who consider contagion, or the generation in fever of specific febrifacient matter, as totally imaginary; and conceive in instances where fever has spread by communication, that either certain undetected conditions in the air, or the confined effluvia of animal excretions accumulated by want of cleanliness and ventilation, with other circumstances, are causes sufficiently adequate to produce the affection, without supposing the agency of a specific and occult power.

"The remote causes of fever," says Dr. Cullen, "are certain sedative powers applied to the nervous system, which diminishing the energy of the brain, thereby produce a debility in the whole of the functions, and particularly in the action of the extreme vessels."

The Treatment of Fever.

In the treatment of fever it is particularly necessary to diminish the cold in the cold stage, the heat in the hot stage, and not to await the senative process of nature, either of dissolving spasm, or of correcting and expelling morbific matter. The various remedies employed for these purposes are, the external and internal use of cold and warm water; refrigerants, sudorifics, opiates, emetics, purgatives.

"The safest and most advantageous time," says Dr. Currie "for using the cold water is, when the exacerbation is at its height, or immediately after its declination has begun; and this has led me almost always to direct it to be employed from six to nine in the evening; but it may be safely used at any time of the day, *when there is no sense of chilliness present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse perspiration.*

"Under these restrictions," our author adds, "the cold effusion may be used at any period of fever; but its effects are more salutary in proportion as it is used early. When employed in the advanced stages of fever, where the heat is reduced and the debility great, some cordial should be given immediately after, and the best is warm wine."

From the urgency however, of the debility, or from the prejudices of the patient or his friends, in some periods of fever, even the application of cold water in the way of ablution may be regarded as too severe. In this case tepid ablution has been made to supply its place and often with propriety and success. The term tepid is applied by Dr. Currie to water, from 87° to 97° of Fahrenheit; from 87° to 75° the water is denominated cool. Cold water may be given internally, and with the utmost freedom, in the hot stage of the febrile paroxysm. Its use, however, requires to be carefully regulated by the same restrictions as in the external application; it must never be given unless the heat of the surface be steadily above the natural standard. Draughts of cold water have been known, when properly administered, to procure a sudden solution of the disease.

Cold air. The extraordinary melioration in the modern practice of medicine, as it relates to the treatment of fever and febrile diseases is not confined to the copious use of effusion and ablution. The terrors of our predecessors in relation likewise to cold air, are fast de

parting; and the importance of its free admission in the apartments of the febrile sufferer especially, comes to be generally acknowledged and applied.

The utility of cold air in fever is referable to two principles: 1st. That of immediately lowering the heat of the surface, and thus taking off the oppression occasioned by such heat: and 2ndly, from affording a larger quantity of oxygen at each inspiration.

The admission of cold air requires to be restricted to the hot stage, and to be limited by the patient's feelings; a current of cold air passing rapidly over the body while in a state of perspiration, may be productive of fatal consequences. Besides, however, the employment of cold water, and the free admission of a cool and pure atmosphere, other agents have been had recourse to, and with considerable effect, in order to abate the inordinate heat of fever. From possessing the faculty of cooling the system, certain medicines have been distinguished by the term refrigerants: refrigerants are principally chosen from the vegetable acids, and the different neutral salts; and so evident is their power in reducing animal temperature, that they have properly been made to constitute a considerable part of regimen in fever.

Of Sudorifics.

Moisture on the surface of the body may be procured by medicines which appear to have a direct power over the cutaneous vessels, or by those whose action seems to be directed primarily to the stomach. These last are principally of the saline class, which are by far the most suitable in the febrile state.

Of Purgatives and Emetics.

Nothing, perhaps, is of greater moment in almost every stage and every kind of fever, than to preserve the whole of the alimentary canal free from accumulations of colluvies, &c. From a deficient attention to this principle, the medical practitioner is in many instances foiled in the treatment of this, and indeed in a variety of other diseases. Viscidities and impurities in the stomach and bowels, are often both the effect and cause of the persistance of the febrile state. In the primary stages of fever, an emetic has been known abruptly to arrest its progress, and the same purpose is sometimes accomplished, especially in ephemeral affections of the febrile kind, by the employment of a brisk purgative. In the more advanced periods however of the disorder, the object of the physician ought to be rather that of keeping the bowels gently open, and this is best effected by saline in place of drastic purgatives; the former of which princpally operate by exciting the exhalants on the internal surface of the intestines to pour out their contents, the latter by stimulating in a forcible manner the intestinal fibre. In intermittent fevers it is generally necessary to evacuate the bowels by more stimulant cathartics, more especially when the cure of these fevers is conducted by the Peruvian bark. If during fever, indicating in its primary stages no particular severity of disease, a rapid change takes place in the feelings and expressions of the invalid; if upon the more ordinary symptoms, suddenly and unexpectedly supervene delirium, prostration of strength, an observable change in the countenance, accompanied by irregular [illegible] partial alternations of heat and cold, without [illegible] intervention of the perspiring state, the patient's life is in considerable danger. The above changes are often indeed preludes to a speedy death.

Weakness, quickness, and irregularity of pulse, delirium, tendency to fainting when in an erect posture, prostration of strength, partial and irregular sweats, difficult respiration and deglutition, starting of the tendons, unusual fœtor in the excretions, great foulness of the tongue and fauces, are all evidences of a fatal tendency in the complaint; in general likewise it may be observed, that in cases where marks of great nervous irritation attend the onset of a fever, even though the disorder may not assume what has erroneously been termed the putrid type, much danger is to be apprehended.

Calculations respecting critical days have been in some measure forced and systematic. It is worthy however of remark, that continued fevers as well as intermittent, in the successive stages of their course, are disposed to assume progressively the quotidian, tertian, and quartan aspect.

Recapitulation of the treatment of Fever.

Treatment of continued fever during the first three or four days. Cold affusion. Water to be impregnated with salt, its application to be confined to the hot stages of the paroxysm. Large draughts of cold water taken under the same limitation. Cold and pure air. Emetics. Purgatives. Antimonia and saline sudorifics.

After the fifth or sixth day. Cold and tepid ablution. Water employed to be impregnated with salt or mixed with vinegar. In the urgency of debility, coldness, or delirium, prediluvium or the warm bath. Bowels to be kept gently but constantly open, by saline or mild purgatives and subacid drinks. While the skin is preserved moist by diaphoretics, give opiates and wine; these last are almost invariably improper when the skin is dry and hot, and the bowels costive. For head-ache and other nervous affections, blisters, æther, camphor. In the last stages, when critical sweats break out, and the powers of life appear to be shrinking from the contest, repeated glasses of port wine with tincture of opium in large quantities. During the whole course of the disease, the apartment to be diligently preserved cool, clean, constantly ventilated, and free from all individuals but those who are necessary attendants on the sick.

Treatment of intermittent fever. Cold affusion immediately upon the full accession of the hot fit. Warm bath, warm spiced wine, during the cold stage of the paroxysm Tincture of opium, either previous to the accession of the cold, or towards the decline of the hot fit. Emetics, immediately preceding the accession of the paroxysm. Calomel purges before the administration of tonics; arsenic, zinc, Peruvian bark, quasia. and if any enlargement of one of the viscera (ague cake) appear, steel. Hope: upon the excitation of hope the power of charms altogether depends; these sometimes succeed in ague, when other remedies are counteracted by the violence of the complaint.

ORDER II.—*Phlegmasiæ*, Inflammations.

When any part of the body has an unusual

heat and redness, with pain and swelling, it is said to be inflamed. To constitute this state of a part, an inordinate action and dilation of vessels have generally been esteemed sufficient.

Sthenic and asthenic inflammation. The disturbance of the system does not correspond more with the magnitude of the local disorder, than with the constitutional character of the individual affected. Of two persons that are the subjects of inflammation, as of the mucous membrane of the nostrils, constituting inflammatory catarrh, or a cold; of the pulmonary vessels, occasioning inflammation of the lungs; or of the joints, forming rheumatism; one shall previously have possessed much constitutional vigour, the other shall have been languid and feeble—the former will have a sthenic, the latter an asthenic disease.

Termination of inflammation. Inflammation is said to be resolved when the natural state and action of parts are renewed without disorganization. If however the inflammation has existed for any time, or has been violent, an unnatural secretion takes place from the vessels inflamed, which is called pus; this when collected or confined, constitutes an abscess, and when the inflammation ends in this manner, it is said to terminate by suppuration. In cases of much weakness, constitutional or induced, the vascular action in the part shall cease altogether, its excitability be irrecoverably exhausted, and what in scholastic language is termed gangrene be the consequence, which extending, shall form sphacelus, or morification. Resolution, suppuration, gangrene, are therefore the usual modes in which inflammation terminates. There are others, however, which are peculiar to certain parts; thus, an inflammation of the lungs often ends fatally by a copious effusion of a watery matter into the cellular texture of these organs; thus an inflammation of a gland shall end in schirrus, or hardness of the parts.

Species of inflammation. This disorder is systematically divided into two leading species—phlegmonous and erithematic. The first is defined by Dr. Cullen, "an inflammation of a bright-red colour, with a circumscribed pointed tumour, and tending towards suppuration." The erythema has a less vivid colour, with scarcely any tumour, spreading irregularly, burning rather than throbbing pain, and terminating in vesicles.

Indications of the disorder's decline. It scarcely requires to be observed, that a cessation of pain, a reduction of tumour, a loss of redness and heat, a diminution of the systematic disturbance, are all evidences that the inflammation is about to terminate. If however it be suffered to run on into the stage of suppuration, the indications of this state are, the pulse becoming fuller and softer, the patient being attacked with shiverings, and a pulsatory feel in the affected part. The tendency to gangrene is denoted by the tumour losing its redness, and assuming a darker hue; by the sudden cessation of pain; sometimes by blisters arising near or upon the tumour; and, lastly, if the local disorder have been considerable, by a rapid declension of the pulse, and powers of life.

Treatment. The indications of cure are to be deduced from the sthenic or asthenic disposition of the disease, and from the peculiar nature of the part or organ injured.

If inflammation be attended by a full, hard, and vigorous pulse, with other expressions of power, a debilitating plan of treatment is to be adopted; blood is to be drawn from the arm, saline purgatives are to be administered, cold is to be applied, and the exciting powers, as much as possible withdrawn. If, on the contrary, an equal degree of local affection shall be accompanied with feeble, although quick, pulse, and the remaining symptoms of debility, an opposite plan, under certain regulations and exceptions, is to be pursued; stimulants are to be thrown in, and the inflammation cured by impelling and supporting the torpid and feeble powers of the frame. But from the peculiar nature of the part or organ affected, the mode of treatment in the same degree and kind of inflammation will likewise be materially modified. Thus an asthenic affection of the liver requires different stimuli from an asthenic affection of the stomach. But although in inflammation, as in fever, we generally recommend the cool treatment, and consequent free admission of air, it is to be recollected that this principle is objectionable in some kinds of inflammations, as of the lungs. For example, in small-pox and in measles, we shall have the same degree of pyrexia, or fever, present; and cold air would be equally indicated in either, were we to infer the proper method of treatment alone from the inflammatory excitement; but in measles the lungs are often the principal seat of the local affection, an oxygenous or pure atmosphere would prove too stimulating to these organs; and thus if we pursued general doctrines without particular exceptions, or overlooked "the peculiar nature of the part or organ injured," the object of our plans would be frustrated and defeated.

Genus I. *Ophtalmia,* inflammation of the eyes.

Genus II. *Phrenitis,* inflammation of the brain. This, as a sthenic affection, independently of proper maniacal disorder, or febrile affection, is an extremely rare disease.

Symptoms. Redness of the face and eyes impatience of light and sound, watchfulness, and furious delirium.

Methodus memendi, or method of cure. Copius evacuations. "Foment the head with cold water for hours together." Blisters. Blood to be drawn from the temporal artery.

N. B. The delirium of fever, which has been supposed to indicate an inflammation of the brain, is for the most part of an asthenic nature, and requires a stimuli.

Genus III. *Cynanche,* quinsy.

Species 1st. Cynanche tonsillaris, common inflammatory sore throat.

M. M. Acid gargles, Saline purgatives. Blisters. Antimonial diaphoretics.

Species 2nd. Cynanche maligna. An accidental, but very common, symptom of scarlet fever. See SCARLATINA.

Species 3rd. Cynanche trachealis. croup, See INFANCY.

Species 4th. Cynanche pharyngææ, a mere extension into the pharynx of the cynanche tonsillaris.

Species 5th. Cynanche parotidæ. The mumps is an affection of the parotid and maxillary glands, which appears in the form of a

swelling under the jaws; it sometimes appears as an epidemic.

M. M. If delirium supervene upon the retrocession of the swellings, blisters. "Foment the head with warm water." *Darwin.*

Genus IV. *Pneumonia,* inflammation of the lungs.

Genus V. *Carditis,* inflammation of the heart or pericardium.

Genus VI. *Peritonitis,* inflammation of the peritoneum.

The general symptoms are, pyrexia, pain in the chest, difficulty of breathing, cough: and if the disorder happen in the sthenic diathesis, the pulse is hard and frequent. Sometimes the expectoration is tinged with blood.

The particular symptoms are, in carditis, palpitation, with unequal intermitting pulse, pain in the region of the heart, vomiting, fainting: if the inflammation be particularly directed to the diaphragm, the pain is situated towards the lower ribs, the respiration in a recumbent posture is extremely difficult, and the corners of the mouth are sometimes so retracted as to form a disagreeable smile, called risus sardonicus.

M. M. If the constitution is sthenic, and the disorder urgent, immediate and copious bleeding. Refrigerant and emollient cathartics. Cool and equal, not cold and irregular, atmosphere. Diluent drinks. Total abstinence from animal food, sometimes during the first five days. Antimonial preparations. After venesection a blister on the pained part. Digitalis. Small doses of calomel to prevent adhesions. If pneumonia run on into suppurations pus will be discharged by cough, and thus a species of consumption be formed; or will be detained in the cavity of the chest, and constitute empyema. In either case, digitalis in large doses. Calomel. Opium. Peruvian bark.

Genus VII. *Gastritis,* inflammation of the stomach.

Symptoms. Violent pain in the region of the stomach, with pyrexia; small, frequent, and sometimes contracted, pulse; vomiting; hiccough.

Causes. It may be occasioned by any thing acrid taken into the stomach: by blows on the region of this organ; and a slight species of it is often consequent upon taking cold liquids after exercise.

M. M. In inflammation of the stomach and bowels we have, in some measure an exception to the general rule of cure, according as the disease appears sthenic or asthenic. The pulse and vital powers are often suddenly reduced, and yet venesection is required. Warm bath. Fomentations. Anodyne and mucilaginous clysters. Blisters on the pained part.

Genus VIII. *Enteritis,* inflammation of the bowels; fixed and distressing pain in the bowels. Pyrexia; pulse always quick, sometimes hard.

Causes. The same as of gastritis. Likewise strangulated hernia, spasmodic colic, introsusception.

M. M. The same as in gastritis after the urgent symptoms have subsided. Small doses of calomel and opium.

Genus IX. *Hepatitis,* inflammation of the liver.

Symptoms. Pain in the region of the liver, extending to the clavicle and top of the right shoulder; difficulty of lying, on the left side especially. Pyrexia; high-coloured urine; pulse frequent, strong, and often hard. Bilious evacuations, or jaundice. The tendency of the disease is to suppuration.

M. M. Copious and repeated bleeding before the suppurative process has commenced. Calomel, and cathartics of the refrigerant class. Digitalis in considerable doses. Blisters to the region of the liver.

If suppuration takes place, the matter makes its way through the lungs, or the intestinal canal, into the cavity of the abdomen, or through the peritoneum to the surface. During this process opium and bark.

A species of chronic hepatitis is more usual in Britain, and indeed is one of our most common maladies, especially among dram-drinkers.

Symptoms. Obtuse and weighty kind of sensation in the region of the liver; difficulty of lying on the left side; pain in the right shoulder; the countenance slightly marked by hectic; dejection of spirits. Œdema of the ancles.

M. M. Small doses of calomel, with, or without opium. Tonic bitters, such as quassia or gentian. An abstinence from spirituous liquors.

Genus X. *Splenitis,* inflammation of the spleen.

Symptoms. Tension; tumour; heat of the left side; pyrexia; pain increased by pressure.

M. M. Blisters, cathartics, calomel, and digitalis.

Genus XI. *Nephritis,* inflammation of the kidneys.

Symptoms. Pyrexia; pain in the lumbar regions; retraction of the testicle; numbness of the thigh; vomiting; costiveness.

Causes. Alternations of heat and cold: external violence, &c. as in other inflammations, but chiefly in calculi.

M. M. Venæsection. Digitalis, and opium. Nitrous æther. Emollient clysters. Castor oil. Demulcents.

Genus XII. *Cystitis,* inflammation of the bladder.

Pyrexia. Pain and tumour above the pubes; pain in discharging urine: tenesmus.

M. M. Venæsection. Warm bath. Anodyne clysters. Diluents.

Genus XIII. *Hysteritis,* inflammation of the womb.

Heat, pain, tension, and swelling, in the lower belly; pyrexia; vomiting.

M. M. Venæsection. Mucilaginous clysters, with opiates. Anodyne fomentations.

Genus XIV. *Rheumatismus.*

Pyrexia; pains in the joints, frequently extending along the muscles; heat and tumour on the part.

M. M. Leeches to the inflamed joints. Volatile embrocations after the inflammation has in some measure subsided. Calomel, and opium. Sudorifics. Warm bath. Peruvian bark in chronic rheumatism. Volatile tincture of gum guaiacum. Flesh-brush. Sea-bathing. Electricity. Bath waters.

Genus XV. *Odontalgia,* tooth-ache.

Genus XVI. *Podagra,* gout.

Symptoms. Pain in the joints, principally

of the great toe, and especially of the hands and feet returning at intervals Previously to the accession of the inflammation the functions of the stomach are generally disturbed. The fits generally come on in the morning.

Causes and peculiarities. Gout is invariably a disease of the asthenic diathesis. It is produced in a system predisposed to its influence by the indirectly debilitating powers; such as a too liberal indulgence in fermented and spirituous liquor, high-seasoned meats, &c. and likewise by the directly debilitating powers of vegetable and watery food, depressing passions, &c The inflammation of this disease often alternates with, and appears in a manner vicarious of, torpor in other parts of the system; as of the brain producing apoplexy, the stomach constituting dyspepsy, and of the liver giving rise to jaundice: all which symptoms indeed may be considered as part of the disease. On this account gout has been divided into the atonic; that is, where a disposition to the inflammation of the foot is observable, but does not actually take place, the retrocedent, where, after the continuance for some time of such inflammation, it shall seem to be transferred to another part, and thus form a gouty inflammation of the stomach, or other organs; and, lastly, the misplaced, in which the gouty tendency, instead of displaying itself in its ordinary course, falls upon some other organs, as the lungs, the stomach, or the brain.

M. M. In treating gout it should never be forgotten that it is an asthenic disease: while excitement is kept up in the system the paroxysms are suspended. The irregular affections in gout must be combated by stimulants carefully adapted to the excitability; for the spasmodic affections of the stomach, aromatics and bitters, as ginger and quassia. If the head is affected, camphor, musk, ether, opium; these likewise are remedies for the gouty asthma. The Portland powder, which is a composition of bitters and aromatics, may prove highly useful. Regular and steady, and not capricious and merely temporary, abstinence from wine, spirits, and spices. The body to be preserved gently open. Pure air, moderate exercise, encouragement of cheerful habits. Warm and cold sea-bathing. Bath waters. Very small doses of digitalis.

ORDER III.—*Exanthemata,* Eruptions.

The exanthemata are more nearly allied to genuine fever than those disorders of which we have just been treating, as the local affections are consequences rather than causes of the general irritation. They have been called eruptive fevers. They are defined by Cullen, contagious diseases, affecting a person only once during the whole of life, commencing with fever, and succeeded by eruption on the skin.

Genus I. ***Erysipelas,*** St. Anthony's fire.

Symptoms. This disease does not correspond with the whole of the above definition; it is not contagious; and it has frequently been found to recur. The face is the more ordinary seat of this affection. After febrile irritation has commenced, and continued for a short time, during which there is often an unusual drowsiness, and sometimes delirium, the face suddenly becomes bloated, the eye-lids swell, and the skin is red and blistered. If the disorder is violent, or ill-treated, the inflammation and redness extend down the neck, and spread sometimes on the shoulders; the tumid appearance of the countenance increases, delirium supervenes, and the patient has been known to die apoplectic. The erysipelas is an erythematic inflammation. Its seat is the rete mucosum. Its tendency is to gangrene rather than to suppuration. A fatal termination is said to be principally on the 7th, 9th, or 11th days

M. M. In no other affection is it of more urgent moment to decide on the treatment by the nature of the prevailing diathesis. It has been observed, that in large and populous cities St. Anthony's fire almost always appears in the form of asthenia; and in this case requires wine, bark, opium: while in the hardy constitution of the rustic it assumes a sthenic character, and demands the vigorous employment of what has been called the antiphlogistic regimen. Venesection. Saline purgatives. Diluent drinks.

Genus II. ***Pestis,*** the plague, is an epidemic typhoid fever.

Genus III. *Variola,* small pox.

Symptoms. After the pyrexial symptoms have continued for three days eruptions appear on the skin, which on the eighth day contain pus, and at length fall off in crusts.

Species. The small-pox is divided into the distinct, and confluent: the first has more of the sthenic, the latter of the asthenic character. In the former the eruptions are of a phlegmonic, in the latter of an erythematic or spreading nature.

The eruption of the distinct small pox makes its appearance in circumscribed red spots on the face; in the course of two days the body and legs receive their portion. The fever now ceases, the face swells, the pustules enlarge, and on the eighth day are mature. The swelling of the face now goes off, and the hands and feet begin to swell, with a slight return of fever, which soon declines.

In the confluent, or asthenic species, the fits are not so regular; the eruptions are not circumscribed and prominent, but diffused, and scarcely appearing above the skin; a kind of erysipelas sometimes precedes them, and every symptom denotes debility. The fatal termination is often on the eleventh day.

Inoculation. The advantages of inoculation for the small-pox need not be insisted on. The only cautions requisite in preparing for inoculation, are to preserve the bowels free from sordes, and to choose a time for the insertion of the matter when teething, or other irritative processes, are not going on in the system. With respect to the time, inoculation ought to be performed either before the second month or after the second year.

M. M. Cold air. The bowels to be preserved open. Animal food to be denied. If the fever runs high, antimonials and nitre. In the confluent species, the alimentary and intestinal canal is with the utmost solicitude to be preserved free from congestions by purgatives, and the powers of the system supported by opium, bark, small doses of nitre, wine, pure air; vinegar aspersed about the bed, walls, and floor of the apartment. Pediluvium.

Genus IV *Varicella.* The chicken-pox is a very slight disease: the eruptions somtimes assume nearly the character of the distinct

small-pox; but there is not much irritation of the system, and they generally disappear in the course of three or four days from their first breaking out.

Genus V. *Rubeola.* Measles.

Symptoms. Pyrexia, sneezing, inflamed eyes, dry cough, drowsiness; about the fourth day, or later, small red points appear on the skin, which in the course of about three days fall off in branny scales.

M. M. Measles too often lay the foundation of pulmonary consumption, to prevent which the symptoms denoting inflammation of the lungs are to be with much solicitude obviated; and for this purpose small doses of tincture of digitalis are to be preferred to every other medicine. Steady and cool atmosphere, not cold air in currents. Refrigerant cathartics, with calomel. Animal food not to be given. Digitalis, with a very small quantity of opium, for the cough succeeding to measles.

Genus VI. *Miliaria,* miliary fever, is merely a symptomatic eruption of small red pimples about the neck and face, which in two days become white pustules, and desquamate. They have a peculiar smell. Much anxiety and difficulty of breathing precede the eruption. This disorder appears to be a consequence of an improper heating regimen in fever.

Genus VII. *Scarlatina,* scarlet fever.

Symptoms, &c. After pyrexia has lasted about four days, a scarlet eruption appears on the skin, sometimes attended with inflamed tonsils and cervical glands: these last sometimes appear without cutaneous eruption, and the disease has been called cynanche maligna. This disorder is very irregular in its aspect; and often, without much care, fatal in its termination. The unfavourable symptoms are the same as in other fevers. It is a disease principally of children.

M. M. Cold affusion. Cold air. Antimonia's, opium, bark, wine, saline purgatives or enemas, nitre, blisters. See the section on Fever in this article.

Genus VIII. *Urticaria,* nettle-rash. After pyrexia for a day, small red spots, like the stinging of nettles, appear on the skin, which almost vanish during the day, but return in the evening. It scarcely requires any medical treatment. The disease does not last more than two or three days.

Genus IX *Aphtha,* thrush. Spots on the fauces and tongue, by which this disorder is constituted, are almost always symptomatic of other diseased states.

Genus X. *Pemphigus,* "a fever attended by successive eruptions of vesicles about the size of almonds, which are filled with a yellowish serum, and in three or four days subside." The treatment is to be regulated by the nature of the attendant fever.

ORDER IV. *Hemorrhagiæ* Discharges of blood,

The definition of this order is, pyrexia, with profusion of blood, without any external violence: blood when drawn from a vein shewing the buffy coat.

Genus I. *Epistaxis,* bleeding from the nose

Symptoms. Pain or fulness of the head, giddiness, dimness of vision, drowsiness, irritation of the nostrils

M. M. Cold applied to the neck and head. Mechanical pressure, or absorbing substances, to the nostrils. Acids and astringents internally. Avoiding irritation of the body or mind. The bowels to be kept gently open. Nourishing but not stimulating aliment. In the epistaxis of old people, and in cases of much weakness, bark, vitriolic acid, opium. If the disorder is violent, and have depended upon the suppression of some other discharge, such discharge to be restored.

Genus II. *Hemoptysis.* Spitting of blood. Symptoms. Redness of the cheeks, a sensation of weight in the breast, difficult respiration. Saltish taste in the mouth, irritation in the trachæa, coughing up of florid blood.

Causes. Violent irritation of mind or body, sudden vicissitudes of heat and cold, too powerful exertion of the lungs, as in singing, coughing, playing upon wind instruments.

M. M. All irritation and irregularities to be carefully guarded against. Bowels to be kept evacuated by mild purgatives. Manna. Tamarinds. Peruvian or oak-bark, combined with mineral acids, especially, the sulphuric opium. Digitalis in large doses, so as to occasion nausea. "A table-spoonful of common salt." Procure a return of the obstructed discharge.

Phthisis pulmonalis, consumption of the lungs.

Symptoms. Emaciation, weakness, cough, hectic fever, and for the most part an expectoration of pus.

Causes. Pthisical ulceration of the lungs, or confirmed consumption, is ordinarily produced through the medium of tubercles, or small bodies, in the cellular texture of these organs, which by repeated and gradual irritation, at length come to ulcerate and destroy the fabric of the lungs, and produce the symptoms of fully-formed phthisis.

The more immediately exciting cause of pulmonary consumption is generally an exposure to cold, which operates in the manner described under the section catarrh. Consumption, however, may be brought on by amenorrhœa, lues venerea, unseasonably repelled eruptive action on the surface, mental affections, &c.

M. M. In no case, perhaps, is neglect or early mismanagement of disease more pregnant with irremediable evils, than in the instance of consumptive affections. Digitalis properly and timely had recourse to is "the anchor of hope." Warm bathing. A regular temperature in the air that the person breathes. Warm cloathing. Avoiding currents of air. Assiduously guarding against damp, and especially cold application to the feet, as by sitting with the feet on a stone floor, or an oil cloth. Milk diet. Avoiding all spirituous liquors, and spiced or high-seasoned meats. Keeping the bowels gently open by manna, castor-oil, senna, &c. When the lungs have actually become ulcerated after gradual and protracted irritation, very little expectation of recovery can remain. Griffith's mixture, composed of steel, myrrh, and alkali. Digitalis in larger doses, and combined with the above tonic. Uva ursi opium and vitriolic acid. Digitalis combined with calomel. Change of climate. If a tendency to absorption from the surface of pulmonary ulcer could be induced greater than the deposition of it, we might have some prospect of curing

the disease, in its advanced stages. In order to produce this absorption, sailing so as to occasion sea-sickness has been had recourse to. Swinging, riding in a carriage, and other modes of occasioning a degree of vertiginous affection, and consequent nausea, have likewise been recommended and practised. In the confirmed stages of phthisis, animal diet which is nutritive, without being stimulant, ought to be advised.

Genus III. *Hæmorrhois*, the piles.

Weight and pain of the head, vertigo, pain in the anus and loins, swellings and flux of blood from the anus.

M. M. If symptoms of arterial activity accompany the hæmorrhoids, vitriolic acid, with moderate astringents, such as infusion of roses. Temperance, exercise, abstinence from spirituous liquors and spices. Tamarinds. Leniti electuary, sulphur, crystals of tartar. Castor oil. Warm fomentation, by sitting over the steam of heated water. Leeches.

When the hæmorrhoidal flux is attended with much debility, while the bowels are kept open by castor oil and other similar purgatives, the more powerful astringents are to be employed. Steel. Exercise. Generous diet. Cheerful train of thinking.

Genus IV. *Monorrhagia*, immoderate menstrual flux.

Symptoms. Pain in the back and loins, vertigo, difficulty of breathing, flushes of heat and cold, frequent pulse; in cases where the disease is more directly from debility, loss of appetite, paleness of countenance, coldness of the limbs, œdematous swellings about the ancles.

M. M. In the first species, the menstrual irregularity arises from hysteric or nervous affections, and other violent passions. Avoid stimuli of all kinds, mental or physical. Refrigerant cathartics, if costiveness be present. Moderate astringents, such as infusion of roses, and the sulphuric acid. In the menorrhagia of direct debility, astringents, cordials, and stimulants. Peruvian bark and sulphuric acid, opium, alum, port wine. External application of cold water or vinegar. Steel.

ORDER V. *Profluvia.*

Genus I. *Catarrhus*, a cold.

Symptoms. Pyrexia, with increased discharge from the mucous membrane of the nostrils, and in violent cases of the fauces and bronchiæ, with cough.

M. M. Moderate and equal temperature. The bowels to be kept gently open. If the febrile irritation is considerable, sudorifics. Antimonials, nitre. Oleaginous substances may be used to allay the cough; but irritating balsams are in the highest degree detrimental. Liquorice, honey, boiled fig, almond emulsion.

If the phthisical tendency is conspicuous, digitalis.

Genus II. *Dysenteria*, dysentery.

Symptoms. Frequent stools, mixed with mucus, and sometimes with blood, attended with griping and tenesmus, the proper alvine excretions being retained; pyrexia, pulse quick and feeble. The disease is sometimes contagious and epidemic.

Causes. Dysentery depends upon the irritability of weakness, determined by particular circumstances to the alimentary canal; its predisposing and exciting causes are alternations of heat and cold, more especially when accompanied by damp, as when an army is encamped on marshy ground; the putrid miasma arising from the marshes; the contagious effluvia proceeding from the discharge in the disease; and, according to Sir John Pringle, from dead bodies left unburied in the field of battle.

The immediate cause of the symptoms seems to be, a spasmodic construction of the larger intestines, retaining the fæces.

M. M. Calomel, opium, and rhubarb, to relieve the spasm, and discharge the contents of the bowels. Mucilaginous clysters, as of starch with tincture of opium. Emetics. Small doses frequently repeated of ipecacuan. Colombo. Peruvian bark. Warm bathing.

CLASS II. *Neuroses*, Nervous diseases.

Nervous diseases are affections of either sense or motion; without idiopathetic pyrexia, or visible disease of parts.

1. Comata. A diminution of voluntary motion, with sleep or impaired senses.
2. Adynamiæ, a diminution of the involuntary motions of either natural or vital functions.
3. Spasmi, morbid motions of muscular fibre.
4. Vesaniæ, disorders of the judgment or intellect without primary pyrexia or observable affection of any particular part of the body.

ORDER I. *Comata.*

Genus I. *Apoplexia*, apoplexy.

Symptoms. Abolition of the sentient and locomotive faculties, the sleep in general attended with snoring. The respiration, motion of the heart, and other involuntary actions, remaining. We conclude from analogy, that there is some degree of pressure on the brain in almost all cases of apoplectic stupor.

Apoplexy may be divided into sthenic and asthenic. If a vigorous and plethoric man, sitting down to his dinner and his glass, suddenly, during the excitement of conviviality, of mirth, and of alcohol, fall on the floor with deprivation of sense and apoplectic stertor, it must be evident that the fit has been induced by a greater flow of arterial blood into the vessels of the brain, than the veins of this organ could, in due time, convey away. The apoplexy has been induced in the manner of a sthenic disease.

If, on the other hand, a debauched and debilitated individual be the subject of an apoplectic attack, at the time when the excitement of intoxication shall have been succeeded by the condition of indirect debility, the disease will here have been brought about in a different manner; the impetus in the vessels of the brain shall have partaken of the general diminution of power throughout the whole system; sluggish vascular action shall have caused congestion; which congestion, in union with the deficient excitement on which it had depended, shall have induced that sudden suspension of the sentient faculty which constitutes the apoplectic paroxysm.

M. M. If the disease is sthenic, and the physicians are called in while the paroxysm still continues, immediate and copious bleeding from the arm, the jugular veins, or the temporal artery. Every ligature about the patient's body, especially about the neck, to be loosened immediately. Press hard with the thumb and fore-finger upon the carotid arteries, taking care to avoid the jugular veins. Place the head of the patient high on his pillow, or seat him erect in a chair. Preserve the apartment cool. Cold water may in some cases be applied vigorously to the forehead and temples. Afterwards saline purges, and subacid drinks. Enemas. Careful preservation from irregular and violent excitations, either of body or mind. In the asthenic, and by far the most usual form of the complaint, bleeding with much less freedom and only during the paroxysm. It is better to open the temporal artery, if convenient, than to bleed from the arm or jugulars. The application of cupping-glasses is still preferable; apply blisters to the neck. When the power of deglutition has returned, cordials and stimulants. Opium and wine in very small doses. Volatile alkali. Sprinkle vinegar about the room. To prevent the returns of the fits; tonics, particularly bitters, as colombo, gentian, quassia: exercise and mental amusement, without violent excitation. Preserve the body regularly open, without violent purgations. Avoid sudden exposure to cold, especially cold and wet feet. If the fit has followed the suppression of any accustomed discharge, or cutaneous eruption, let them, if possible, be restored.

Genus II. *Paralysis*, palsy.

Partial interruption of the loco-motive faculty, sometimes with a degree of apoplectic stertor. This is partial apoplexy, arising from similar causes operating in a less degree. It sometimes succeeds to a full fit of apoplexy, and continues for months, or during life. The palsy often affects the whole of one side, and is confined to that side; hence it has been supposed, that the injury of the brain is likewise partial.

M. M. Ascertain the exciting cause, and if possible counteract it. Emetics, purgatives, preceding stimulants and tonics. Tonics and stimulants the same as in asthenic apoplexy. Volatile embrocations to the paralyzed side or limb. Warm bath. Bath waters. Electricity. Galvanism.

ORDER II. *Adynamiæ.*

Genus I. *Syncope*, fainting.

Symptoms. A diminution or even, for a time, a total cessation, in the action of the heart.

Fainting may arise from passions of the mind: from sudden reduction of stimulus, as from bleeding, or drawing off the waters in dropsy; violent pain; the irritation of worms, or other crudities, in the stomach and bowels: much heat, offensive effluvia, &c.

M. M. Immediately obviate, if possible, the exciting cause. Endeavour to restore sensation by aspersing cold water on the face and neck; attempts to force down a small quantity of brandy: and in all cases, but more especially when the affection arises from impure air, throw open the windows, and prevent compassionate spectators from crowding round the insensible patient.

Genus II. *Dyspepsia*, indigestion.

Symptoms. Deficient, or depraved appetite; nausea; vomiting; inflation from flatulence; heart-burn; pain in the stomach, especially when the body is in a bent position; oppressed breathing; costiveness.

This disease evidently arises from the same sources as other affections of weakness: these are, intemperate use of spirituous liquors, and of tea; exposure to damp and cold; irregular hours of repose; intense study; mental depression and anxiety.

M M. Purgatives, with calomel, previously to giving tonics. An emetic. Columbo, gentian quassia. Magnesia, in order to neutralize the acidity, and ease the consequent pain of heart-burn. Cold or shower bath, in very warm, and warm bathing in cold weather. A glass of warm water after dinner and supper.

Genus III. *Hypochondriasis*, low spirits.

Indigestion, with languor, and causeless apprehension of evil, more especially as it relates to the patient's state of health.

M. M. Aim at converting solicitude and apprehension into confidence and hope; not by deriding the feelings of the hypochondriac, and treating them as fanciful, but by breaking the chain of diseased associations. Procure a gradual change of scene and of habits. Bath waters. Warm bathing. Preserve carefully the alimentary canal free from colluvies and viscidities by drastic purges and calomel. Maintain a regular moisture of the skin, without copious perspiration. Tonics with aromatics.

Genus IV. *Chlorosis*, green-sickness.

Dyspepsia; paleness of the skin and of the lips; lassitude; difficult breathing, and palpitation of the heart, after using more exercise than usual; pulse small, feeble, and sometimes very quick: coldness of the extremities; appetite deficient, and oftentimes depraved; pain in the back and loins; costiveness; œdematous ancles, especially towards evening; and obstructed menstruation.

M. M. Almost as certainly as some kinds of pain yield to opium, does even obstinate chlorosis fall before the power of steel. It is necessary, however, frequently to commence with an emetic; and in almost all cases it is proper to give a purgative, joined with calomel, before the administration of steel. Tonic bitters. Aromatics. Moderate exercise in a pure atmosphere. Meat diet. A bath of about eighty degrees. Marriage.

ORDER III. *Spasmi.* Spasms.

SECT. I. *Spasmodic affections in the animal functions.*

Genus I. *Tetanus.* A spasmodic rigidity of a great part of the body: in some instances it is drawn violently backward, at others forwards, and in both cases the disease is generally followed or attended by trismus or lock-jaw. The immediately exciting causes of tetanus are, wounds or pricks of tendons; the sudden application of cold after extreme heat; great intemperance, or other vices: the disease may likewise be consequent upon viscid mucus, worms, and other irritating substances, in the alimentary passages.

M. M. Pouring large quantities of cold water over the body during the spasm, in order forcibly to sever the catenated motions by which it is constituted. Warm bathing. Very large quantities of opium. Other antispasmodic medicine. Mercury. If the spasm has originated from a lacerated or punctured tendon, divide it freely, and produce pain and inflammation.

Genus II. *Convulsio,* convulsions. On the cause and treatment of these, we need not enlarge, after the remarks we have introduced on the nature, predisposing and exciting causes, of convulsive and spasmodic disorders in general.

Genus III. *Chorea,* St. Vitus's dance.

Symptoms. Convulsive agitations of the limbs, in general almost confined to one side of the body. When the patient attempts to walk, he produces involuntary gesticulations.

M. M. Emetics, cathartics with calomel; anthelmintics; bark, steel, and other tonics; electricity, galvanism, tepid bathing, sea-bathing.

Genus IV. *Raphania,* contractions in the joints.

Symptoms. Spastic contractions of the joints, with excruciating pain, and convulsive motions, returning periodically, and continuing for many days. It appears to be a species of rheumatism.

M. M. Purges, followed by tonics; mercury combined with opium.

Genus V. *Epilepsia,* epilepsy. Violent convulsions of the muscles, attended with sleep.

Epilepsy in its nature and causes appears to hold a kind of intermediate situation between apoplexy and convulsion; it has the sudden fall and the sopor of the one, with the irregular muscular action of the other.

M. M. Epileptic fits are sometimes congenital, hereditary, and depend upon some occult state of the nervous system. In these cases the disorder is generally irremediable. All that can be done by art is merely to ascertain, and endeavour, if possible, to obviate the exciting causes of the disease; and during the paroxysm to loosen every bandage about the neck and head, preserve the apartment as airy as possible, and be careful that the patient do not inflict injury upon himself by the violence of his agitation.

Particular attention is to be given to the predisposing and exciting cause or causes, which are extremely numerous; such as youthful intemperance, indulgence in secret vices, mental passions and affections, imitation of other epileptics, lively recollections of previous impressions, repelled eruptions or discharges, sudden alternations of the extremes of temperature, unpleasant odours, and worms. These causes must all necessarily be removed before the physician can have the least prospect of overcoming the disease. Emetics, cathartics, with calomel; anthelmintics: suddenly dissever the chain of associations, by plunging the patient in the cold bath, or dashing with violence cold water over his naked body.

Of Worms and Anthelmintics.

Intestinal worms are of three kinds; the ascaridis, or small thread-like worm; the lumbricus teres, or round worm; and the tænia, or tape worm. The first of these are principally confined to the rectum. The symptoms by which the presence of these may be suspected, are an uneasiness and itching in the rectum, especially urgent towards evening: this, if violent, disturbs sleep, and occasions febrile irritation, and sometimes tenesmus, with mucous discharge from the anus, indigestion, and itching of the nostrils.

M. M. Clysters of lime-water, injection of tobacco-smoke. Mercurial ointment introduced into the anus. Aloes and steel, both by the mouth and in the form of enema. Saline purgatives. Harrowgate water, so as to induce six or seven stools every morning. The lumbricus is the most common. Lumbrici are of very different lengths and magnitude; they are principally found in the smaller intestines, but are situated occasionally both in the stomach and larger intestines. These worms have been known to pierce through the coats of the alimentary canal, and have thus occasioned most excruciating pains and death. The tape-worms are sometimes voided of an enormous length; they have been stated to be from two to forty feet long. They properly consist of an united chain of separate animals; as, when broken, each portion has the power of reproduction. The symptoms are much the same with those of the lumbrici, but more urgent.

M. M. Dolichos pruriens, cowhage. E. and W. Indies. This substance is the down growing on the pods of the plant.

Ferrum, iron.—The filings and rust.

Stannum, tin.—This is used in the form of power. Tin may perhaps operate by a mechanical hower. Dose, one or two drachms.

Submurias hydrargiri.—Calomel is perhaps the most efficacious of all the anthelmentics. Dose ten or twelve grains to an adult.

Spasmodic Affections continued.

SECT. II. *In the vital Functions.*

Genus I. *Palpitatio,* palpitation See Syncope.

Genus II. *Asthma.*

Symptoms. Difficult respiration returning at intervals, with a sense of tightness across the breast. Wheezing at the commencement of the asthmatic fits; scarcely any cough but what is hard; towards the close of the paroxysm it however becomes more free, attended with a discharge of mucus.

The causes of asthma are numerous, while its predisposition is often hereditary, and dependant upon a peculiar conformation and temperament; the actual disease may be excited by intemperance either in eating or drinking, violent exercise, mental agitation, eruptions or discharges abruptly or unseasonably repelled; the fumes of metallic poison, as of lead, &c.

M. M. Spasmodic asthma, when fully established, scarcely admits of a radical cure. The paroxysms to be relieved by opium and æther; coffee; tonics in the intervals principally of the class of bitters and aromatics. Avoid distending the stomach inordinately. Emetics; enemas previous to the expected accession; gentle horse exercise; pure air; oxygen gas. If eruptions have been repelled, endeavour to restore them.

Genus III. *Dyspnœa*, difficulty of breathing. This is improperly introduced into the nosology as a genus, it being merely a symptom of other diseases, consequent upon defective formation of the chest, or brought on by evident causes, which being removed, the disorder immediately declines.

Genus IV. *Pertussis*, hooping cough.

Symptoms. Convulsive strangulating cough, with noisy inspiration or hooping, and sometimes attended with vomiting. It is contagious.

M. M. Antimonial emetics. Very small doses. Warm bathing. Above all, digitalis; in no disease, perhaps, is the power of this valuable medicine displayed more forcibly and evidently than in hooping cough. Its effects are generally almost instantaneous. After the violence of the disease has subsided, and even before, change of air.

SECT. III. *In the animal functions.*

Genus I. *Pyrasis.* Water-brash of Scotland. Water-qualm.

Symptoms. Sudden eructation of watery fluid with or without heartburn; the fluid brought from the stomach sometimes insipid.

M. M. Inhalation of tobacco smoke. A grain of opium twice a day, soap, iron powder, a blister.

Genus II. *Colica*, colic.

Symptoms. Permanent and excruciating pain in the belly, with a sensation as of twisting about the navel, constipation, and sometimes vomiting

Causes. These symptoms may be occasioned by indigestible food, the sudden application of cold; acrid substances received into the stomach; poisons, especially lead hence colic is a kind of epidemic disease among painters, attended with paralysis of the arms, &c.

M. M. Opium. Cathartics, principally of castor oil. Warm bathing. Anodyne clysters. Fomentations and blisters to the part. In obstinate cases of the painters' colic, Bath waters. Carefully obviate the exciting causes of the disease.

Genus III. *Cholera.*

Symptoms. Vomiting and purging of bilious matter, violent pains in the stomach and bowels, with great anxiety and irritability.

Cholera is one of the diseases of the autumnal months: it is very often produced by the sudden succession of cold to unusually warm weather: it sometimes follows the taking of indigestible substances, as of much cold cucumber.

M. M. During the violence of the vomiting and purging, give water-gruel, and inject starch clysters, to each of which add tincture of opium. After the disorder has in some measure subsided, restore due excitement by cordial and nourishing diet, with stomachic medicines. If frebrile irritation is induced, the saline draught, composed of salt of wormwood and lemon-juice.

Genus IV. *Diarrhœa.*

Symptoms. Frequent stools, without primary pyrexia, and not induced by contagion.

A morbid action in the excretories of the intestines constitutes this disease; sometimes however, and frequently, purging arises from mere loss of excitability in the intestinal fibre; without increase either of bile or any other excretion It is immediately occasioned by acrid matter in the intestines; by acidities, by mental passions, or by the sudden application of cold, more especially to the feet.

M. M. According to the exciting causes. If there is reason to suspect the lodgment of acrid matter, calomel, with jalap, senna, or rhubarb. Afterwards astringents, of which one of the best is good red wine. Opium. Chalk, if acidity prevails. An emetic if the disorder continues obstinate.

Genus V. *Diabetes.*

Symptoms. Superabundant discharge of urine, in some cases amounting to fifty pounds in twenty-four hours, limpid and sweetish to the taste, with urgent and perpetual thirst, dry skin, weakness, emaciation.

M. M. Animal diet. Alkaline and astringent medicines, such as nut-galls and lime-water. Bark. Steel. Opium. Alum-whey.

Genus VI. *Hysteria.* The hysteric disease.

Symptoms. A gurgling of the bowels, followed by globus hystericus, or a sensation of a ball ascending to the throat, and menacing suffocation. Convulsive agitations, alternate laughing and crying, a general fickleness and irritability of mind. A large quantity a straw-coloured or limpid urine. Hysteria, like epilepsy, generally first occurs in females about the time of puberty. It is, a systom of a lax habit, and is consequent upon the irritability of weakness. It may be brought on by mental agitation or by irritations in the stomach, bowels, uterine organs, &c.

M. M. Avoid every occasional and exciting cause of the disease. Bark, quassia, and other tonics. To remove the present symptoms, camphor, asafœtida, castor opium; if this last, from idiosyncracy, disagrees with the patient, the hyoscyamus will generally be found an excellent substitute. Emetics.

Genus VII. *Hydrophobia.*

A dread of water as exciting painful convulsions of the pharynx caused for the most part by the bite of a mad dog, violent spasms, furious insanity, death.

M. M. Dr. Thornton advised the application of hot vinegar, sharpened with vitriolic acid, to the wounds of five men who had been bitten by a rabid animal, and this application was attended with seeming success. Mercury: this by some has been extolled as a specific for hydrophobia. See HYDROPHOBIA.

ORDER IV. *Vesaniæ.*

Disorders of the intellect independant of pyrexia or coma.

Genus I *Amentia*, ideocy.

Amentia is defined an imbecility of judgment, preventing the perception or the recollection of the relations of things.

There are three species: connate; from old age; from intemperance, and other external causes. When firmly established, little hopes of recovery can be entertained

Genus II.—Melancholia

Genus III.—Mania.

Insanity is intensity of idea, converting imagination into implicit belief, and thus producing an incongruity of action. It par-

takes of the character of mania or melancholia, of a violent rage or gloomy despondency, according to the previous temperament of the sufferer, and the nature of the prevailing idea.

M. M. Endeavour to draw off the mind from the prevailing idea, or otherwise to convince the maniac of the errors of his conceptions, and fallacy of his pretensions, by relating the incongruous conceits of other maniacs which have some affinity with his own. In incipient and equivocal madness, cautiously abstain from expressing suspicions in the hearing of the patient. "Nothing is more calculated to make a person mad than the idea of being thought so." On this account, premature confinement is to be deprecated, as injudicious in the extreme. Those who are placed over the insane as guardians, should unite decision and firmness of character with tenderness of disposition and gentleness of manners.

In strong plethoric habits, venesection. Cathartics. These last, especially in melancholy, often require to be of the drastic kind, and united with calomel. "Diarrhœa very often proves a natural cure of insanity." Vomits. Camphor. Opium in large doses Cold bathing during the violence of the paroxysms, and in some cases, warm bathing in the intervals. During the urgency of phrenzy, apply cold water to the head. Clay cap. Blisters to the scalp. In some cases the production of a vertiginous state, by a rotatory swing, has been found effectual in breaking the morbid associations constituting phrenetic and melancholy paroxysms. Digitalis in very large doses, but regulated with care. Introducing a new disease, which is of a trivial nature, and easy of cure.

Genus IV.—*Oneirodynia* is a violent and distressing imagination in time of sleep. It is divided into two species: the active, or that exciting to walking and various other motions; and the gravans, with a sense of weight or pressure on the chest. This last is the incubus of authors, or night-mare.

The incubus, or night-mare, appears to arise from an interruption of the circulation of blood through the lungs, from defective irritability in these organs, induced by fatigue, mental oppression, a full supper, and wine; which last, in some persons, will almost invariably induce the disease.

M. M. Temperance; especially moderate suppers. "To sleep on a hard bed with the head raised." Emetics. Pugatives of aloes and calomel. Tonics. Sleeping in a large airy apartment, and without curtains to the bed.

CLASS III. *Cachexiæ.* Cachexies.

ORDER I. *Marcores.*

A wasting of the body or general emaciation.

Genus I. *Tabes.* Asthenia, emaciation, and hectic.

Genus II. *Atrophia.* Asthenia, and emaciation without hectic.

M. M. In atrophia, a supply of nourishment, equivalent to the loss that may have been sustained; if emaciation has arisen from mental disturbances, the remedies must chiefly be made to apply to the mind. Tonics from the vegetable class, such as colomba, quassia, and gentian; not steel. Abate the febrile irritation, by keeping the bowels gently open by the milder purgatives, such as manna, senna, and castor oil. Preserve a slight moisture of the skin by small doses of antimonials. Regular and moderate, not violent or agitating exercise. Shower-bath in very warm, tepid bathing in cold weather. Pure air.

In tabes, or emaciation, accompanied by primary hectic. An emetic, to accomplish the double purpose of forcibly expelling ventricular and intestinal acidities, and exciting the languid absorbents. Drastic purgatives, as jalap or aloes, with calomel, with the same intention. Steel, in conjunction with Peruvian bark or bitters. Horse exercise. Warm bathing.

ORDER II. *Intumescentiæ, general swellings.*

Sect. I. *Adiposæ.* Fatty swellings.

Genus I. *Polysarcia,* obesity. This arises from the deposition of oil in the adipose membrane becoming disproportionate to the requisitions of the body.

M. M. Temperance, exercise, less animal food, early rising.

Sect. II. *Flatuosæ,* windy swellings.

Genus I. *Pneumatosis,* a tense elastic swelling of the body, crepitating under the touch.

M. M. Scarifications, compresses, tonics.

Genus II. *Tympanites,* a windy swelling of the abdomen, tense, elastic, painful, and attended by costiveness.

Tympanitic swellings often take place in conjunction with anasarca, or other disorders of debility, and frequently arise from sedentary habits, hypochondriac ailments, and innutritious diet.

M. M. Carminatives, emetics, tonics, and a generous diet, with exercise.

Genus III. *Physometra,* an elastic swelling in the hypogastrium, consequent upon flatulent distension of the womb.

This frequently deceives the barren female with the hopes of pregnancy, till nature explains the mystery, and her expectations vanish in air.

Sect. III. *Aquosæ.* Watery swellings.

Dropsical enlargement is distinguished from pneumatosis by its being inelastic, or pitting from the pressure of the finger, and slowly recovering its former fulness. Dropsy is a collection of serous fluid, either in the cellular membrane, or in the cavities of the body. It is invariably occasioned by exhalation being disproportionate to absorption; this increase of exhalation and diminution of absorption result from debility, which may be either direct or indirect; the latter follows increased action of the vessels, as in the dropsy succeeding to intemperance; the former arises out of deficient excitement in the lymphatic system, as when an individual becomes dropsical from indolence, inactivity, mental depression, and poverty of diet.

Genus I. *Anasarca.* General dropsy.

Dropsy of the cellular membrane immediately under the skin appears principally in the lower extremities, on account of the depending situation of these members, and the universal connection between the cells of which the membrane is constituted. Anasarca, as it arises from exhausted excitability in the lymphatic

vessels, is always a disorder indicating much danger.

M. M. Those stimuli which are found to exert their influence on the absorbent vessels, particularly steel, digitalis, calomel. Diuretic, such as squills, juniper, nitrous æther, cantharides, chrystals of tartar, and nitre. Emetics and cathartics are less proper in anasarca than in dropsy of cavities. The physician must be especially careful while evacuating the fluid by means of diuretics, to support the general excitement, in order to prevent its reaccumulation. The sparing use of liquids is generally proper in dropsy; instances, however, have been known of copious draughts of water producing a termination of the complaint.

Genus II. *Hydrocephalus,* dropsy of the brain.

Genus III. *Hydrorachitis,* dropsical tumour in the spine.

Genus IV. *Hydrothorax,* dropsy of the chest.

Symptoms. Difficulty of breathing, especially in a horizontal position, paleness of countenance, starting in sleep, palpitation of the heart, numbness of the arms, especially when elevated, and in the advanced stages of the malady an evident fluctuation of water in the cavity of the chest.

Causes. Where the universal has preceded the local affection, the malady is most frequently to be traced to intemperance in the use of fermented and spirituous liquors. The most usual source of genuine hydrothorax, or hydrops pectoris, is the sudden application of cold, while the body is in a state of perspiration and debility, from previous heat and exercise.

M. M. Digitalis in considerable doses is especially indicated in dropsy of the chest. Squill, in combination with calomel, for the hydrops pectoris; and if the cellular membrane be anasarcous, connect steel with both the above medicines. Chrystals of tartar, especially in the anasarca pulmonum. Diuretics of other kinds, the same as in general anasarca. Opium. In hydrothorax, or dropsy of the chest, without anasarca, paracentesis, or puncture in the side.

Genus V. *Ascites.* Dropsy of the abdomen. The swelling of the abdomen is tense, scarcely elastic, but fluctuating. Ascites is attended with scarcity of urine, thirst, and after some time a degree of hectic fever. Ascites most usually originates through the medium of a diseased liver; and such disease is, in the greater number of instances, itself induced by intemperance in spirituous liquors.

M. M. If the water is independant of disease in the liver, chrystals of tartar, digitalis, other diuretics, and steel, may be immediately had recourse to, without the intervention of calomel purgatives and of emetics, which last are almost always indicated in the more usual form of ascites, that form a morbid affection of the biliary organs. Emetics in hepatic ascites are often attended with most beneficial effects. A combination of gamboge, elaterium, and calomel, is frequently employed as a purgative in ascites. Mercurial ointment to the region of the liver. Tonics, especially steel.

Genus V. *Hydrometria.* Dropsy of the womb. It is characterized by dropsical swelling, confined to the region of the uterus, not being accompanied by other symptoms of dropsy. It is a disease to which the unmarried and the barren are principally obnoxious; sometimes it follows abortion.

M. M. Stimulant fomentations. Drastic purgatives. Aromatic fœtid gums. Emmenagogues.

SECT IV. *Solidæ.* Swellings of solid parts.

Genus I. *Physconia.* A swelling chiefly occupying a portion of the abdomen, increasing gradually, and neither tense nor sonorous as in pneumatosis, nor fluctuating as in dropsy. This disease is principally formed by a schirrous state of the several parts and viscera, which form its seat. These schirrous enlargements are generally incurable.

Genus II. *Rachitis.* Rickets.

ORDER III. *Impetigines,*

Deformities and discolourations of the external surface from general disease.

Genus I. *Scrophula.* King's evil.

Swellings of the lymphatic glands, terminating in ulcer, are perhaps the only proper characteristics of actual scrophula. A scrophulous habit is merely a susceptibility of disease, arising from torpor in the lymphatic vessels, and when brought on by the agency of exciting causes, consists in a peculiar action of the lymphatic glands, by which inflammation and at length ulceration, with a discharge of grumous matter, are induced. Its exciting causes are those which encourage the original debility, and the disease may almost certainly be avoided by attention to diet and regimen; by nutritious food, a pure oxygenous atmosphere, cleanliness, exercise, &c. When by neglect, the predisposition has been permitted to break out into disease, calomel purges, steel, small doses of digitalis, warm and sea-bathing, muriates and phosphates of barytes; above all cleanliness; ventilation, stimulating nutritious diet. Let the mind be preserved free from the erroneous idea, that to cure scrophula is to purge away gross humours.

Genus II. *Syphilis.* Venereal disease.

After impure connection, a disorder of the genitals, ulcers in the mouth and nose Eruptions on the skin of a copper colour, terminating in ulceration; these are principally situated near the margin of the hair; blotches on the surface of the body, especially on the surface of the face. Nocturnal pains in the centre of the bones.

M. M. Mercurials. Nitric acid. Tonics.

Genus III. *Scorbutus,* scurvy.

Indolence and lassitude; gloomy and tumid countenance; gums livid, and disposed to bleed spontaneously, or from the slightest irritation; skin dry, and covered with livid spots; œdematous swellings of the ancles. Scurvy appears to originate from want of, or exhausted excitement, both in the venous and absorbent system; it is produced by a protracted course of salt food, and by mental depression.

M. M. Fresh animal and vegetable diet. Juice of lemon. Bark. Steel. Terrene atmosphere. Mental excitement.

The elephantiasis, lepra, frambæsia, and trichoma, forming the fourth, fifth, sixth, and seventh genera of this order, are diseases of such rare occurrence in this country, as not to require any particular description.

Genus III. *Icterus*, jaundice

Symptoms. Yellowness of the skin and eyes; white and slimy fæces: high-coloured urine, tinging linen yellow; languor, lassitude, and extreme depression of spirits. The yellow colour of the skin, which constitutes jaundice, arises from the diffusion through the system of that bile, which, in the natural course, would pass through the biliary ducts into the intestinal canal. This interruption of the biliary secretion may originate from a spasmodic affection near the duct; from chronic inflammations, or other diseases of the liver interfering with the secretion; from certain concretions lodging in some part of the he[illegible]ic organs, called gall-stones; and, as pointed out by Mr. Townsend, from viscid mucus stopping up or obstructing the biliary passages.

The first of the above species of jaundice is generally of a temporary nature. The second species follows upon a long course of intemperance in spirituous [illegible]quors, and is only to be remedied by removing the disease of the liver itself. The biliary calculi, which give rise to the third species of jaundice, appear to arise from some defective action in the secretory or absorbing vessels of the parts in which they are formed or lodged. Their presence may be ascertained from jaundice frequently disappearing and returning, from the appearance of biliary concretions among the fæces, and from the disease being attended with shooting pains in the epigastric region, and right hypochondrium. Nausea, difficult respiration, and sickness, often likewise accompany this species of jaundice. The mucosus is unattended either by pain or spasmodic affections; there are no gall-stones observed in the fæces; but these are generally discharged mixed with much slime and viscidities. It is generally accompanied with, and most commonly occasioned by, a depression of mind, especially when favoured by sedentary habits, breathing an impure atmosphere, living upon unwholesome innutritious diet, or indulging in the too free use of "spirituous potation."

M. M. Emetics. Calomel purgatives. Bitter. Tonics, especially colombo, with rhubarb. Pure air. Exercise on horseback. Mental excitement. In icterus spasmodicus, opium, assafœtida, æther, electricity. If the spasm depends upon any irritations in the stomach or bowels, these to be removed by emetics, purgatives, anthelmintics. In icterus calculosus, emetics to facilitate the passage of the gall-stones. Antispasmodics, Warm bathing. Emollient clysters. Vegetable tonics, and steel.

MEDIETAS LINGUÆ, a jury or inquest impanelled, whereof the one-half consists of natives or denizens, the other strangers; and used in pleas wherein the one party is a stranger, the other a denizen.

MEDIUM, in logic, the mean or middle term of a syllogism, being an argument, reason, or consideration, for which we affirm or deny any thing; or, it is the cause why the greater extreme is affirmed or denied of the less in the conclusion.

MEDIUM, or MEAN, *geometrical*. See MEAN.

MEDIUM, in philosophy, that space or region through which a body in motion passes to any point; thus æther is supposed to be the medium through which the heavenly bodies move; air, the medium wherein bodies move near our earth: water, the medium wherein fishes live and move; and glass is also a medium of light as it affords it a free passage. That density or consistence in the parts of the medium, whereby the motion of bodies in it is retarded, is called the resistance of the medium, which together with the force of gravity, is the cause of the cessation of the motion of projectiles.

MEDUSA, a genus of vermes of the order mollusca. The animals of this genus consist of a tender gelatinous mass of different figures, furnished with arms or tentacular processes, proceeding from the lower surface: the larger species, when touched, cause a slight tingling and redness, and are usually denominated sea-nettles; they are supposed to constitute the chief food of cetaceous fish, and most of them shine with great splendour in the water. There are 44 species.

MEERSCHAUM. Keffekil of Kirwan. Colours, yellowish and greyish-white. Massive. Dull. Fracture fine earthy. Fragments angular. Opaque. Streak slightly shining. Does not soil. Very soft, sectile, but rather difficultly frangible. Adheres strongly to the tongue. Feels rather greasy. Sp. gr. 1.2 to 1.6. Before the blowpipe, it melts on the edges into a white enamel. Its constituents are, silica 41.5, magnesia 18.25, lime 0.50, water and carbonic acid 39.—*Klaproth.* It occurs in the veins in the serpentine of Cornwall. When first dug, it is soft, greasy, and lathers like soap. Hence the Tartars use it for washing clothes. In Turkey it is made into tobacco pipes, from meerschaum dug in Natolia, and near Thebes.

MELANITE. Colour, velvet-black. In roundish grains, but more frequently crystallized in a rhomboidal dodecahedron, truncated on all the edges. Surface of the grains rough and uneven; that of the crystals shining. Fracture flat conchoidal. Opaque. As hard as quartz. Rather easily frangible. Sp. gr. 3.73. Its constituents are, silica 35.5, alumina 6, lime 32.5, oxide of iron 25.25, oxide of manganese 0.4, loss 0.35. It is found in a rock at Frescati near Rome, and in the basalt of Bohemia.

MELALEUCA, a genus of the polyandria order, belonging to the polyadelphia class of plants. The species are 11, natives of India and the South-sea islands. The most remarkable is the leucadendron, from a variety of which the cajeput oil is obtained; a medicine in very high esteem among the Eastern nations, particularly in India. It is said to be obtained by distillation from the fruit of the tree. It is applied externally where a warm and peculiar stimulus is requisite; it is employed for restoring vigour after luxations and sprains, and for easing a violent pain in gouty and rheumatic cases, in tooth-ache, and similar affections.

MELAMPYRUM, *cow-wheat*, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. There are five species, four of them natives of Britain, and growing spontaneously among corn-fields. They are excellent food for cattle; and Linnæus says, that where they abound, the yellowest and best butter is made.

MELEAGRIS, in ornithology, the turkey, a genus of birds belonging to the order of gallinæ. The head is covered with spongy

caruncles; and there is likewise a membranaceous longitudinal caruncle on the throat. There are but two species, viz. the gallopavo, or North American turkey of Ray; and the satyra, or horned turkey. The first has a caruncle both on the head and throat; and the breast of the male is bearded or tufted. It lives upon grain and insects; when the cock struts, he blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forehead, and the naked parts of the face and neck become intensely red. The turkey hen begins to lay early in the spring, and will often produce a great number of eggs, which are white, marked with reddish or yellow spots, or rather freckles. She sits well, and is careful of her young; of which she will often have from 14 to 17 for one brood: but she scarcely ever sits more than once in a season. Turkeys are bred in quantities in some of the eastern counties of England, and are driven up to London towards autumn for sale in flocks of several hundreds, which are collected from the several cottages about Norfolk, Suffolk, and neighbouring counties, the inhabitants of which think it well worth their while to attend carefully to them, by making these birds a part of their family during the breeding-season.

MELIANTHUS, *honey-flower*, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 24th order, corydales. The calyx is pentaphyllous, with the lowermost leaf gibbous: there are four petals, with the nectarium under the lowest ones. The capsule is quadrilocular. There are three species.

MELISSA, *baum*, a genus of the didynamia gymnospermia class of plants. There are six species.

Baum is greatly esteemed among the common people as good in disorders of the head and stomach; but is less regarded in the shops. It is most conveniently taken in infusion by way of tea; the green herb is greatly better than the dry, which is contrary to the general rule in relation to other plants.

MELLATES, in chemistry, are compounds, of mellitic acid with the salifiable bases.

MELLITE, *honeystone, mellat of alumina.* This mineral was first observed about 10 years ago in Thuringia, between the layers of wood coal. It is of a honey-yellow colour, and is usually crystallized in small octahedrons. Fracture conchoidal. Specific gravity from 1.5 to 1.7. When heated it whitens, and in the open air burns without being sensibly charred. A white matter remains, which effervesces slightly with acids, and which at first has no taste, but at length leaves an acid impression upon the tongue.

MELLITIC *acid,* in chemistry, is procured from the substance just described, by the following process. The mineral is reduced to powder, and boiled with about 72 times its weight of water; the alumina is precipitated in the form of flakes, and the acid combines with the water. By filtration and evaporation, crystals are deposited, which are the crystals of mellitic acid; they are in the form of fine needles, or in small short prisms with shining faces; they have a slightly acid taste, accompanied with some degree of bitterness. This acid is not very soluble in water; its constituent parts are carbon, hydrogen, and oxygen. The acid enters into combination with the earths, alkalis, and metallic oxides, and forms compounds denominated mellates.

MELOCHIA, *Jew's mallow,* a genus of the pentandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The capsule is quinquelocular and monospermous. There are 11 species: but the only remarkable one is the olitorous, or common Jew's mallow, which is a native of the warm parts of Asia and America. It is an annual plant. This species is cultivated about the city of Aleppo in Syria, and in the East Indies, as a pot-herb; the Jews boiling the leaves, and eating them with their meat.

MELODY, in music, the agreeable effect of different sounds, ranged and disposed in succession; so that melody is the effect of a single voice or instrument, by which it is distinguished from harmony.

MELOE, a genus of insects of the order coleoptera: the generic character is: antennæ moniliform, with the last joint ovate; thorax roundish; wing-sheaths soft, flexile; head inflected. Among the principal species of meloe may be numbered the meloe proscarabæus, commonly called the oil-beetle. It is of considerable size, often measuring near an inch and a half in length; its colour is violet-black, especially on the antennæ and limbs; the wing-sheaths are very short, in the female insect especially, scarcely covering more than a third of the body, and are of an oval shape. On being handled it suddenly exsudes from the joints of its legs, as well as from some parts of the body, several drops of a clear deep-yellow oil or fluid, of a very peculiar and penetrating smell. This oil or fluid has been highly celebrated for its supposed efficacy, in rheumatic pains, &c. when used as an embrocation on the parts affected; for this purpose also the oil expressed from the whole insect has been used with equal success.

The *meloe scabrosus* extremely resembles the preceding, and is found in similar situations, but differs in being of a reddish purple colour, with a cast of deep gilded green.

Meloe vesicatorius, blister-fly, or Spanish fly, is an insect of great beauty, being entirely of the richest gilded grass-green, with black antennæ.

MELON. See CUCUMIS.

MEMORY, is that faculty of the human mind by which it retains the ideas it has once acquired. Memory, says Mr. Locke in his Essay on the Human Understanding, is, as it were, the store-house of our ideas; for the narrow mind of man not being capable of having many ideas under view at once, it was necessary to have a repository in which to lay up those ideas which it may afterwards have use of. But our ideas being nothing but actual perceptions in the mind, which cease to be any thing when there is no perception of them; this laying up of our ideas in the repository of the memory, signifies no more than this; that the mind has a power in many cases, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them before. And it is by the assistance of this faculty, that we are said to have all those ideas in our understandings which we can bring in sight, and make the object of

our thoughts, without the help of those sensible qualities which first imprinted them there. Attention and repetition help much to the fixing ideas in our memories; but those which make the deepest and most lasting impressions, are those which are accompanied with pleasure and pain. Ideas but once taken in and never again repeated, are soon lost; as those of colours in such as lost their sight when very young. The memory of some men is tenacious almost to a miracle; but yet there seems to be a constant decay of all our ideas, even of those which are struck deepest; and in minds the most retentive. Those ideas that are often refreshed by a frequent return of the objects or actions that produce them, fix themselves best in the memory, and remain longest there: such are the original qualities of bodies. In memory, the mind is oftentimes more than barely passive; for it often sets itself on work to search some hidden ideas; sometimes they start of their own accord; and sometimes tempestuous passions tumble them out of their cells. This faculty other animals seem to have to a great degree, as well as man.

Memory, *artificial*, a method of assisting the memory by forming certain words, the letters of which shall signify the date or æra to be remembered. In order to this, the following series of vowels, diphthongs, and consonants, together with their corresponding numbers, must be exactly learned, so as to be able at pleasure to form a technical word, that shall stand for any number, or to resolve such a word already formed.

a	*e*	*i*		*u*	*au*	*oi*	*ei*	*ou*	*y*
1	2	3		5	6	7	8	9	0
b	*d*	*t*		*l*	*s*	*p*	*k*	*n*	*z*

The first five vowels, in order, naturally represent 1, 2, 3, 4, 5, the diphthong *au* = 6, as being composed of *a* and *u*, or 1 + 5 = 6: and for the like reason, *oi* = 7, and *ou* = 9. The diphthong *ei* will easily be remembered for 8, as being the initials of the word. In like manner, where the initial consonants could conveniently be retained, they are made use of to signify the number, as *t* for 3, *f* for 4, *s* for 6, and *n* for 9. The rest were assigned without any particular reason, unless that possibly *p* may be more easily remembered for 7, or septem, *k* for 8, or ὀκτώ, *d* for 2, or duo; *b* for 1, as being the first consonant; and *l* for 5, being the Roman letter for 50; than any others that could have been put in their places.

It is further to be observed, that *z* and *y* being made use of to represent the cypher, where many cyphers meet together, as 1000, 1000000, &c. instead of a repetition of *a z y z y z y*, &c. let *g* stand for 100, *th* for a thousand, and *m* for a million. Thus *ag* will be 100, *ig* 300: *oug* 900, &c. *ath* 1000, *am* 1000000, *loum* 59000000, &c.

Fractions may be set down in the following manner: let *r* signify the line separating the numerator and denominator the first coming before, the other after it; as *iro* $\frac{3}{4}$, *urp* $\frac{5}{7}$, *pourag* $\frac{79}{100}$, &c. When the numerator is 1 or unit, it need not be expressed, but begin the fraction with *r*; as *re*, $\frac{1}{2}$ *ri* $\frac{1}{3}$, *ro* $\frac{1}{4}$, &c. So in decimals, *rag* $\frac{1}{100}$, *rath* $\frac{1}{1000}$.

This is the principal part of the method which consists in expressing numbers by artificial words. The application to history and chronology is also performed by artificial words. The art herein consists in making such a change in the ending of the name of a place, person, planet, coin, &c. without altering the beginning of it, as shall readily suggest the thing sought, at the same time that the beginning of the word being preserved, shall be a leading or prompting syllable to the ending of it so changed. Thus, in order to remember the years in which Cyrus, Alexander, and Julius Cæsar, founded their respective monarchies, the following words may be formed; for Cyrus, Cyr*uts*; for Alexander, Alex*ita*; for Julius Cæsar, Juli*os*. *Uts* signifies, according to the powers assigned to the letters before-mentioned 536; *ita* is 331; and *os* is 46. Hence it will be easy to remember, that the empire of Cyrus was founded 536 years before Christ, that of Alexander 331, and that of Julius Cæsar 46.

This account is taken from a treatise, entitled, a New Method of Artificial Memory; where the reader will find several examples in chronology, geography, &c. of such artificial words disposed in verses, which must be allowed to contribute much to the assistance of the memory, since being once learned, they are seldom or never forgotten. However, the author advises his reader to form the words and verses himself in the manner described above, as he will probably remember these better than those formed by another.

We shall, in this place, give his table of the kings of England since the Conquest, where one thousand being added to the italics in each word, expresses the year when they began their reigns. Thus,

Will con*sau*, Rul*koi*, Hen*ray*.
Steph*bil* and Hensec*buf*, Rich*bein*, Ja*nn*,
Heth*das* and Ed*doid*.
Edse*typ*. Edter*tep*, Rise*tois*, Hefo*toun*,
Hefi*sadque*.
Henfi*led*, Edquar*fauz*, Efi-Ro*kt*, Hensep*feil*,
Henoc*lyn*.

primse*l*,
Casse*sok*, Jam*seif*, Wil*seik*, An*pyd*, Geo-
bo-doi.

MENDICANTS, or begging friars, several orders of the religious in popish countries, who, having no settled revenue, are supported by charitable contributions.

MENISCUS. See Optics.

MENISPERMUM, a genus of the diœcia dodecandria class and order. There are 13 species, herbs of the East Indies.

MENNONITES, a sect of baptists in Holland, so called from Mennon Simonis of Friezland, who lived in the sixteenth century. This sect believed that the New Testament is the only rule of faith; that the terms person and trinity are not to be used in speaking of the Father, Son, and Holy Ghost; that the first man was not created perfect; that it is unlawful to swear or to wage war upon any occasion; that infants are not proper subjects of baptism: and that ministers of the gospel ought to receive no salary.

MENSTRUUM, in chemistry the fluid in which a solid body is dissolved.

MENSURATION, in general, denotes the act or art of measuring lines, superfices, and solids; and it is, next to arithmetic, a

subject of the greatest use and importance, both in affairs that are absolutely necessary in human life, and in every branch of mathematics; a subject by which sciences are established, and commerce is conducted; by whose aid we manage our business, and inform ourselves of the wonderful operations in nature; by which we measure the heavens and the earth, estimate the capacities of all vessels and the bulks of all bodies, gauge our liquors, build edifices, measure our lands and the works of artificers, buy and sell an infinite variety of things necessary in life, and are supplied with the means of making the calculations which are necessary for the construction of almost all machines. To offer here a general view of this subject would very much exceed our bounds; the leading principles will be found developed under other articles of which, we must take more ample notice; and as our object is not to thrust in matter for the sake of swelling our pages, but to give the reader as great a variety of useful information as possible, we must refer him to those articles. See NAVIGATION, SURVEYING, and TRIGONOMETRY.

MENTHA, mint, a genus of the gymnospermia order, in the didynamia class of plants; and in the natural method ranking under the 42d order, verticillatæ. There are 19 species; but not more than three are cultivated for use, namely, the viridis, or common spearmint, the piperita or peppermint, and the pulegium or pennyroyal. All these are so well known as to need no description; and all of them are very easily propagated by cuttings, parting the roots, or by offsets. For culinary purposes, the spearmint is preferred to the other two; but for medicine, the peppermint and pennyroyal have almost entirely superseded it.

The virtues of mint are those of a warm stomachic, capable of relieving colicky pains, and the gripes, to which children are subject. It likewise proves a useful cordial in languors and faintness. Pennyroyal has the same general characters with the mint, but is more acrid and less agreeable when taken into the stomach.

MENYANTHUS, buckbean, a genus of the pentandria monogynia class of plants, with a monopetalous funnel-like flower, divided into five deep segments at the limb; the fruit is an oval capsule with one cell, containing a great many small seeds. There are five species.

MERCHANT, a person who buys and sells commodities in gross, or deals in exchanges; or that traffics in the way of commerce, either by importation or exportation. Formerly every one who was a buyer or seller in the retail was called a merchant, as they are still both in France and Holland, and in some parts of Scotland; but in England shopkeepers, or those who attend fairs or markets, have lost that appellation.

The following epitome of the qualifications requisite in a merchant, are well deserving the serious attention of every youth who has the prospect of being employed in commercial transactions. A merchant should therefore be acquainted with the following parts of commercial learning: 1. He should write properly and correctly. 2. Understand all the rules of arithmetic that have any relation to commerce. 3. Know how to keep books of double and single entry, as journals, a ledger, &c. 4 Be expert in the forms of invoices, accounts of sales, policies of insurance, charter-parties, bills of lading, and bills of exchange. 5. Know the agreement between the money, weights, and measures of all parts. 6. If he deals in silk, woollen, linen, or hair manufactures, he ought to know the places where the different sorts of merchandizes are manufactured, in what manner they are made, what are the materials of which they are composed, and from whence they come, the preparation of these materials before working up, and the places to which they are sent after their fabrication. 7. He ought to know the lengths and breadths which silk, woollen, or hair-stuffs, linen, cottons, fustians, &c. ought to have, according to the several statutes and regulations of the places where they are manufactured, with their different prices, according to the times and seasons; and if he can add to his knowledge the different dyes and ingredients which form the various colours, it will not be useless. 8. If he confines his trade to that of oils, wines, &c. he ought to inform himself particularly of the appearance of the succeeding crops, in order to regulate his disposing of what he has on hand, and to learn as exactly as he can, what they have produced when got in, for his director in making the necessary purchases and engagements. 9. He ought to be acquainted with the sorts of merchandise found more in one country than another, those which are scarce, their different species and qualities, and the properest method of bringing them to a good market. 10. To know which are the merchandises permitted or prohibited, as well on entering as going out of the kingdoms or states were they are made. 11. To be acquainted with the price of exchange, and what is the cause of its rise and fall. 12. To know the customs, due on importation of merchandises, in the places to which he trades. 13. To know the best maner of folding up, embaling, or turning the merchandises. 14. To understand the price and condition of freighting, and insuring ships and merchandize. 15. To be acquainted with the goodness and value of all necessaries for the construction, repairs, and fitting out of shipping; with the different manner of their building. 16. To know the wages commonly given to the captains, officers and sailors, and the manner of engaging with them. 17. He ought to understand foreign languages, particularly the French, Spanish, Italian, and German. 18. He ought to be acquainted with the consular jurisdiction, with the laws and customs of the different countries, and in general all the ordinances and regulations both at home and abroad that have any relation to commerce.

A material requisite for forming a merchant is, his having on all occasions a strict regard to truth, and his avoiding fraud and deceit as corroding cankers, that must inevitably destroy his reputation and fortune. Trade is of so universal a nature that it is impossible for the laws of one country to determine all the affairs relating to it; therefore all nations, as well as Great Britain, shew a particular regard to the LAW MERCHANT, which is a law made by the merchants among themselves: however, merchants and other strangers are subject to the laws of the country in which they reside.

MERCURIALIS, *mercury*, a genus of the enneandria order, in the diœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. There are six species. Of these, the *perennis*, according to Mr. Lightfoot, is of a sophorific deleterious nature, noxious both to man and beast.

MERCURY is distinguished from all other metals by its extreme fusibility, which is such, that it does not take the solid state until cooled to the thirty-ninth degree below 0 on Fahrenheit's thermometer; and of course it is always fluid in the temperate climates of the earth. Its colour is white, and rather bluer than silver. In the solid state it is malleable; its specific gravity is 13.6. It is volatile, and rises in small portions at the common temperature of the atmosphere, as is evinced by several experiments, more especially in a vacuum, such as obtains in the upper part of a barometer tube. At the temperature of about 656° it boils rapidly, and rises copiously in fumes. When exposed to such a heat as may cause it to rise quickly in the vaporous form, or about 600°, it gradually becomes converted into a red oxide, provided oxygen be present. This was formerly known by the name of precipitate *per se*. A greater heat, however, revives this metallic oxide, at the same time that the oxygen is again extricated. Ten days, or a fortnight's constant heat is required to convert a few grains of mercury into precipitate *per se* in the small way. From this volatility of mercury, it is commonly purified by distillation.

Mercury is not perceptibly altered by mere exposure to the air; though by long agitation, with access of air, it becomes converted into a black powder or oxide, which gives out oxygen by heat, the metal being at the same time revived.

Mercury being habitually fluid, very readily combines with most of the metals, to which it communicates more or less of its fusibility. When these metallic mixtures contain a sufficient quantity of mercury to render them soft at a mean temperature, they are called *amalgams*.

It very readily combines with gold, silver, lead, tin, bismuth, and zinc; more difficultly with copper, arsenic and antimony; and scarcely at all with platina or iron: it does not unite with nickel, manganese, or cobalt; and its action on tungsten and molybdena is not known. Looking-glasses are covered on the back surface with an amalgam of tin. See Silvering.

The amalgamation of the noble metals, water-gilding, the making of vermilion, the silvering of looking-glasses, the making of barometers and thermometers, and the preparation of several powerful medicines, are the principal uses to which this metal is applied.

Scarcely any substance is so liable to adulteration as mercury, owing to the property which it possesses of dissolving completely some of the baser metals. This union is so strong, that they even rise along with the quicksilver when distilled. The impurity of mercury is generally indicated by its dull aspect; by its tarnishing, and becoming covered with a coat of oxide, on long exposure to the air; by its adhesion to the surface of glass; and when shaken with water in a bottle, by the speedy formation of a black powder. Lead and tin are frequent impurities and the mercury becomes capable of taking up more of these, if zinc or bismuth be previously added. In order to discover lead, the mercury may be agitated with a little water, in order to oxidize that metal. Pour off the water, and digest the mercury with a little acetic acid. This will dissolve the oxide of lead, which will be indicated by a blackish precipitate with sulphuretted water.

A fulminating preparation of mercury was discovered by Mr. Howard. A hundred grains of mercury are to be dissolved by heat in an ounce and a half by measure of nitric acid. This solution being poured cold into two ounces by measure of alcohol in a glass vessel, heat is to be applied till effervescence is excited. A white vapour undulates on the surface, and a powder is gradually precipitated, which is immediately to be collected on a filter, well washed, and cautiously dried with a very moderate heat. This powder detonates loudly by gentle heat, or slight friction.

Red oxide of mercury is acrid and poisonous, and carries these qualities into its saline combinations. The protoxide is relatively bland, and is the basis of all the mild mercurial medicines.

Mercury, in astronomy, the smallest of the planets, and the nearest the sun. See Astronomy.

MERGUS, in ornithology, a genus of birds of the order of anseres; distinguished by having the beak of a cylindrical figure, and hooked at the extremities, and its denticulations of a subulated form.

1. The *cucullatus*, or crested diver of Catesby, has a globular crest, white on each side; and the body is brown above, and white below. This elegant species inhabits North America. It appears at Hudson's bay the end of May, and builds close to the lakes.

2. The *merganser*, or goosander, weighs four pounds; its length is two feet four inches; the breadth three four. The dun-diver, or female, is less than the male; the head and upper part of the neck are ferruginous; the throat white; the feathers on the hind parts are long, and form a pendant crest: the back, the coverts of the wings, and the tail are of a deep ash-colour; the greater quill-feathers are black, the lesser white; the breast and middle of the belly are white, tinged with yellow. The goosander seems to prefer the more northern situations to those of the south.

3. The *albellus*, or smew, weighs about 34 ounces; the length is 18 inches, the breadth 26; the bill is near two inches long, and of a lead colour; the head is adorned with a long crest, white above and black beneath; the head, neck, and whole under part of the body, are of a pure white; the tail is of a deep ash-colour, the legs a blueish grey. The female, or lough-diver, is less than the male; the back, the scapulars, and the tail, are dusky; the belly is white. There are three other species.

MERIDIAN. See Astronomy, and Geography.

Meridian *line*, on a dial, is a right line arising from the intersection of the meridian of the place, with the plane of the dial.

Meridian, *magnetical*, is a great circle passing through the magnetic poles, to which the magnetic needle, or needle of the mariner's compass, conforms itself.

MERIDIONAL distance, in navigation, is the same with the departure, easting or westing, or the difference of longitude between the meridian under which the ship now is, and any other meridian she was before under.

Meridional parts. See Navigation.

MERLIN. See Falco.

MERLON, in fortification, that part of a parapet which is terminated by two embrasures of a battery. Its height and thickness is the same with that of the parapet; but its breadth is generally nine feet on the inside, and six on the outside. It serves to cover those on the battery from the enemy; it should be made of earth well beat and close.

MEROPS, a genus of birds of the order picæ. Generic character: bill quadrangular, somewhat curved, compressed, and pointed; nostrils small, at the base of the bill; tongue slender, and in some species ciliated, the outer toe somewhat connected with the middle one. Gmelin notices twenty-six species and Latham twenty. M. apiaster, or the common bee-eater; this is about ten inches long, and found in many countries of Europe, though never observed in Great Britain. It is particularly fond of bees, but will eat various other insects; many of which it seizes, like the swallow, on the wing. When insects are with difficulty to be found, it feeds on many species of seeds.

MESENTERY. See Anatomy.

MESNE, he who is lord of a manor, and so has tenants holding of him, yet himself, holds of a superior lord.

MESNE PROCESS, is an intermediate process, which issues pending the suit, upon some collateral interlocutory matter, as to summon juries, witnesses, and the like: sometimes it is put in contradistinction to final process, or process of execution; and then it signifies all such process as intervenes between the beginning and end of a suit.

MESPILUS, in botany, a genus of the icosandria pentagynia class and order. Natural order of pomaceæ. Calyx five cleft, petals five; berry inferior, five seeded. There are nine species. M. germanica, Dutch or common medlar, never rises with an upright trunk, but sends out crooked deformed branches, not far from the ground: leaves large, entire, downy on their under side; flowers very large, as also the fruit, which approaches to the shape of an apple. The tree bearing the largest fruit is now generally cultivated; the Nottingham medlar, has a more poignant taste, but the fruit is considerably less.

MESSENGERS, are certain officers chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all kinds of dispatches foreign and domestic. They also, by virtue of the secretaries' warrants, take up persons for high treason, or other offences against the state.

METALS. The most numerous class of undecompounded chemical bodies, distinguished by the following general characters:—

1. They possess a peculiar lustre, which continues in the streak, and in their smallest fragments.

2. They are fusible by heat; and in fusion retain their lustre and opacity.

3. They are all, except selenium, excellent conductors both of electricity and caloric.

4. Many of them may be extended under the hammer, and are called malleable; or under the rolling press, and are called laminable; or drawn into wire, and are called ductile. This capability of extension depends, in some measure, on a tenacity peculiar to the metals, and which exists in the different species with very different degrees of force. See Cohesion.

5. When their saline combinations are electrized, the metals separate at the resino-electric or negative pole.

6. When exposed to the action of oxygen, chlorine, or iodine, at an elevated temperature, they generally take fire, and, combining with one or other of these three elementary dissolvents in definite proportions, are converted into earthy or saline looking bodies, devoid of metallic lustre and ductility, called oxides, chlorides, or iodides.

7. They are capable of combining in their melted state with each other, in almost every proportion, constituting the important order of metallic alloys; in which the characteristic lustre and tenacity are preserved. See Alloy.

8. From this brilliancy and opacity conjointly, they reflect the greater part of the light which falls on their surface, and hence form excellent mirrors.

9. Most of them combine in definite proportions with sulphur and phosphorus, forming bodies frequently of a semi-metallic aspect; and others unite with hydrogen, carbon, and boron, giving rise to gaseous or solid compounds.

10. Many of the metals are capable of assuming, by particular management, crystalline forms; which are, for the most part, either cubes or octohedrons. See Chemistry.

Metal, in heraldry. There are two metals used in heraldry, by way of colours, viz. gold and silver, in blazon called *or* and *argent*. In the common painting of arms these metals are represented by white and yellow, which are the natural colours of those metals. In engraving, gold is expressed by dotting the coat, &c. all over; and silver, by leaving it quite blank.

METALLURGY, comprehends the whole art of working metals from the state of ore to the utensil; hence, assaying, gilding, refining, smelting, &c. are only branches of metallurgy. In a more limited sense, it includes only the operations which are followed in separating metals from their ores. See Assaying, &c.

METAPHOR, in rhetoric, a trope, by which we put a strange word for a proper word, by reason of its resemblance to it; or it is a simile or comparison intended to enforce and illustrate the thing we speak of, without the signs or forms of comparison.

METAPHYSICS. See Philosophy.

METATARSUS. See Anatomy.

METEOR. This term is by some writers made to comprehend all the visible phenomena of meteorology, but it is more generally confined to luminous bodies appearing suddenly at uncertain times, and with more or less of motion in the atmosphere. These may be reduced under three classes, viz. fire-balls, falling or shooting stars, and ignes fatui

Those phenomena which are classed together under the general appellation of fire-balls, were divided by the ancients into several species, according to the external form or appearance which they assumed. In tropical climates these meteors are more common and more stupendous than in these more temperate regions.

Two meteors appeared in England in the year 1783, of which a most particular account and ingenious solution, by Dr. Blagden, are published in the Philosophical Transactions of the following year. The first of these was seen on the 18th of August, and was, in appearance, a luminous ball, which rose in the N. N. W. nearly round: it, however, soon became elliptical, and gradually assumed a tail as it ascended, and, in a certain part of its course, seemed to undergo a remarkable change, compared to bursting; after which it proceeded no longer as an entire mass, but was apparently divided into a cluster of balls of different magnitudes, and all carrying or leaving a train behind, till, having passed the east, and verging considerably to the south, it gradually descended, and was lost out of sight. The time of its appearance was about sixteen minutes past nine in the evening, and it was visible about half a minute. It was seen in all parts of Great Britain, at Paris, at Nuits in Burgundy, and even at Rome: and is supposed to have described a tract of 1000 miles at least over the surface of the earth. The illumination of these meteors is often so great as totally to obliterate the stars, to make the moon look dull, and even to affect the spectators like the sun itself. The body of the fire-ball, even before it burst, did not appear of an uniform brightness, but consisted of lucid and dull parts, which were constantly changing their respective positions, so that the whole effect was to some eyes like an internal agitation or boiling of the matter. By the best accounts that could be procured concerning the height of the meteor, it seems to have varied from 55 to 60 miles. A report was heard some time after the meteor disappeared, and this report was loudest in Lincolnshire and the adjacent parts, and again in the eastern parts of Kent. Judging from the height of the meteor, its bulk is conjectured to have been not less than half a mile in diameter; and when we consider this bulk, its velocity cannot fail to astonish us, which is supposed to be at the rate of more than 40 miles in a second.

It seems to be the opinion of Dr. Blagden and others, that the general cause of these phenomena is electricity; but notwithstanding the ingenious arguments urged in defence of this hypothesis, we still entertain considerable doubts as to its correctness. The duration of the fire-ball, the unequal consistency of the mass, and several other points in the narration, seem to indicate that its materials were of a less rare and evanescent nature than the electric matter.

The shooting or falling-star is a common phenomenon; but though so frequently observed, the great distance and transient nature of these meteors have hitherto frustrated every attempt to ascertain their cause. The connection of these with an active state of the atmospheric electricity, is however certain from observation; and we have more reason to consider them as electric scintillæ than as solid or fluid matter in the act of combustion. They precede a change of wind.

Concerning the nature and composition of the *ignis fatuus*, or Will-with-a-wisp, there is less dispute; the generality of philosophers being agreed, that it is caused by some volatile vapour of the phosphoric kind, probably the phosphorized hydrogen gas. The light from putrescent substances, particularly putrid fish, and those sparks emitted from the sea, or sea-water when agitated, in the dark, correspond in appearance with this meteor. Sir Isaac Newton defines the ignis fatuus to be "a vapour shining without heat;" and it is usually visible in damp places, about dunghills, burying-grounds, and other situations which are likely to abound with phosphoric matter.

METEORIC STONES. Almost all the larger fire-balls have been observed to disappear with a loud explosion; and it was almost constantly affirmed that heavy stony bodies fell from them. But though several well-authenticated accounts of the fall of such stones had been from time to time published, little credit was given to them by philosophers, till Dr. Chladni published a dissertation on the subject in 1794. Two years after, Mr. King published a still more complete collection of examples, many of them supported by such evidence that it was impossible to reject it. Mr. Howard having procured specimens of the stones which were said to have fallen in different places, compared them together, and subjected them to a chemical analysis. The result was, that all these stony bodies differ completely from every other known stone; that they all resemble each other; and that they are all composed of the same ingredients. They are found entirely different from all known stones, and exactly resemble each other, even in their component parts. They are heated and luminous when they reach the earth: the force of their descent buries them some depth into it; and they have been seen under these circumstances in Italy, Germany, France, England, and India. The meteors either really do, or appear to, move horizontally, and are said to descend ere they explode. The stones are of different sizes, and from a few ounces in weight to several tons; they are generally circular, and invariably covered with a rough black crust, which, according to Howard, is principally composed of oxide of iron. The stones which fell at Laigle, in France, in 1803, yielded by the analysis of Vauquelin and Fourcroy, 54 parts silica, 36 oxide of iron, 19 magnesia, 5 oxide of nickel, 2 sulphur, and 1 lime:—and Mr. Howard found that 150 grains of a meteoric stone which fell in Yorkshire, contained 75 silica, 37 magnesia, 48 oxide of iron, 2 oxide of nickel. The oxidizement of the metallic bodies caused this increase of weight.

Various conjectures have been formed as to the origin of these stones; some, with Laplace, supposing them to be ejected by volcanoes in the moon; and others, with Sir W. Hamilton and Mr. King, that they are concretions formed in the atmosphere.

METEOROLOGY, the doctrine of meteors, or the study of the variable phenomena of the atmosphere. The atmosphere may be considered in respect of the direction of its currents or winds; of the variations in its gravity or pressure; of the changes in its temperature; of the state of the electricity which it exhibits; and lastly, as to the visible phenomena which are supposed to depend on the foregoing. Winds, though proverbially uncertain in some climates, are yet not without a striking degree of regularity and system, if we consider the whole atmosphere: and there is a

part of the world where the wind is so constantly in one quarter, that *windward*, in common speech, stands for eastern, and *leeward* for western. We want only a more extensive set of observations to render exceedingly probable the following hypothesis: That a large portion of the whole atmosphere moves constantly from east to west round the earth, on and near the equator; that this is supplied and impelled by air from the temperate and cold latitudes on each side towards the poles; which again receive, by a superior current, the over flow of the tropical regions, where the air, rarefied by the heat, is constantly rising, and tending to lateral diffusion. Winds appear usually to begin at that point towards which they blow. They must therefore be owing to a rarefaction or displacing of the air in some particular quarter, either by the action of heat, or some other cause.

In 1740, Dr. Franklin was prevented from observing an eclipse of the moon at Philadelphia by a north-east storm, which came on about seven o'clock in the evening. He was surprised to find afterwards that it had not come on at Boston till near 11 o'clock: and he found it to be always an hour later the farther north-east for every 100 miles. "From thence (says he) I formed an idea of the course of the storm, which I will explain by a familiar instance. I suppose a long canal of water stopped by a gate. The water is at rest till the gate is opened; then it begins to move out through the gate; and the water next the gate is first in motion, and moves on towards the gate, and so on successively, till the water at the head of the canal is in motion, which it is last of all. Thus, to produce a north-east storm, I suppose some great refraction of the air in or near the Gulf of Mexico; the air rising thence has its place supplied by the next more northern, cooler, and therefore denser and heavier air; a successive current is formed, to which our coast and inland mountains give a north-eastern direction."

The north-east wind blows most frequently with us during the spring months: and from the observations made by Captain Cook, it appears, that the same wind prevails during the same period in the Northern Pacific. Hence it appears, that at that season the cold air from the north of Europe and America flows into the Atlantic and Pacific.

It is very common to observe one current of air blowing at the surface of the earth, while a current flows in a contrary direction in the higher strata of the atmosphere. Three such winds have been observed blowing in contrary directions all at the same time. It is affirmed, that changes of weather generally begin in the upper strata of the air, the wind which blows there gradually extending itself to the surface of the earth.

With regard to the pressure of the atmosphere, it is every where variable, as appears by the barometer; which indicates to us the weight of a column of air, extending to the top of the atmosphere, and whose base is equal to that of the mercury. At the level of the sea, where the column of air is longest, the mean height of the barometer is thirty inches. The mean height of the barometer is less, the higher any place is situated above the level of the sea, because the column of air which supports the mercury is the shorter.

Between the tropics the variations of the barometer are exceedingly small; and it does not descend above half as much for every 200 feet of elevation as it does beyond the tropics. As the latitude advances toward the poles, the range of the barometer gradually increases, till at last it amounts to two or three inches. This will appear, from the following table:

Table of the Range of the Barometer.

Latitude	Places.	Range of the Barometer	
		Greatest	Annual.
0° 0′	Peru	0.20	—
22 23	Calcutta	0.77	—
33 55	Cape Town	—	0.89
40 55	Naples	1.00	—
51 8	Dover	2.47	1.80
53 23	Liverpool	2.89	1.96
59 56	Petersburg	3.45	2.77

In North America, however, the range of the barometer is a great deal less than in the corresponding European latitudes. In Virginia, for instance, it never exceeds 1.1. The range of the barometer is greater at the level of the sea than on the mountains; and in the same degree of latitude, the extent of the range is in the inverse ratio of the height of the place above the level of the sea.

The density of the atmosphere is greatest at the poles, and least at the equator; as the centrifugal force at the latter, the distance from the centre of the earth, and the heat, contributing to lessen the density of the air, are at their maximum, when at the pole it is exactly the reverse. In every part of the world the mean height of the barometer placed at the level of the sea will be found to be 30 inches, consequently, the weight of the atmosphere is the same in all places; its weight depending on its density and height; where the former is greatest the height must be the least, and where its density is least the height is the greatest. It will therefore appear that the height of the atmosphere must be least at the poles, and greatest at the equator, decreasing gradually in the interval, and thus forming the resemblance of two inclined planes, meeting at the highest part above the equator.

The difference of the mean heat between the pole and the equator, when the sun is in our hemisphere in the summer, does not vary so much as in the winter, as the heat at that period in northern countries equals that of the torrid zone.

The pressure of the superincumbent column in a great measure causes the density of the atmosphere, and therefore decreases in proportion to the height as the pressure of the column constantly decreases, yet the density in the torrid zone does not decrease so rapidly as in the temperate and frigid, as the column is longer, and because there is a larger proportion of air in the upper part of it.

The density at the equator, though less at the surface of the earth, must equal at a cer-

tain height, and still higher exceed the density in the temperate zones, and at the poles; but a current of air constantly ascends at the equator, part at least of which reaches to and remains in the highest parts of the atmosphere; but the fluidity of that body prevents it from accumulating above the equator, and hence it must descend the declined plane before mentioned. The surface of the atmosphere being more inclined in the northern hemisphere during our winter than that of the southern, more of the current must flow on the northern than on the southern, from which cause the quantity of our atmosphere is greater in winter than that of the southern hemisphere; in the summer it is just the contrary.

The heat of any given place in a great measure influences the density of its atmosphere; that density will be most considerable where it is coldest, and its column shortest. Chains of mountains, the summits of which are covered with snow great part of the year, and highlands, must be colder than places less elevated in the same latitude, and the column of air over them much shorter. The current of air above must be impeded and accumulated while on its passage over these places towards the poles.

After the accumulations have existed some time the surrounding atmosphere becomes incapable of balancing the density of the air, when it descends with violence, and occasions cold winds, which raise the barometer; it is to this that we are to attribute the rise of the barometer, almost always attending north-east winds in Europe, which is the effect of accumulations near the pole, or in the north-west parts of Asia.

When in the polar regions large quantities of air are casually compressed; the southern atmosphere must rush in to replace it, which occasions south-west gales, and the fall of the barometer.

The mean heat of our hemisphere varying in successive years, the density of the atmosphere, and necessarily, the quantity of equatorial air passing towards the poles, cannot be otherwise than variable; hence occur the different ranges of the barometer, in successive years; at some particular periods, more considerable accumulations take place in the highest parts of Asia, and the south of Europe, than at others, which may be produced by early falls of snow, or the interruption of the sun's rays by long continued fogs; at such times the atmosphere in the polar regions becomes proportionably lighter, and this causes the prevalence of southerly winds in some winters more than in others.

The heat of the torrid zone never greatly varying, the height and density of the atmosphere undergoes but few changes, thence arises the comparatively small range of the barometer within the tropics, which gradually increases towards the poles, as the difference of the temperature and the density of the atmosphere increases with the latitude. The sinking of the barometer preceding violent tempests, and the oscillations during their continuance, prove that very great rarefactions, or even destruction of air, in some part of the atmosphere produce those phenomena; the fall too that accompanies winds arises from the same cause.

There are considerable variations in the temperature of the air in any particular place, exclusive of the difference of the seasons and climates, which change cannot be produced by heat derived from the sun, as its rays concentrated have no kind of effect on air; those however heat the surface of our globe, which is communicated to the immediate atmosphere: it is thus that the temperature is highest where the place is so situated as to receive with most effect the rays of the sun, and that it varies in each region with the season; it is also the cause why it decreases in proportion to the height of the air above the surface of the earth. The diminution of temperature from the pole to the equator takes place in arithmetical progression; or the annual temperatures of all the latitudes are arithmetical means between the mean annual temperature of the equator and the pole.

The mean temperature of the equator being 84 deg. and that of the pole 31 deg. to find the mean annual temperature for every other latitude, we have only to find 88 arithmetical means between 84 and 31.

It has been found that in every degree of north latitude, January is the coldest month; July the warmest in all above 48 deg. in lower, August. Every latitude where existence can be maintained has a mean of 60 deg. two months of the year at the least, which is requisite for the production of those articles by which man supports life. The temperatures within ten degrees of the poles vary little, and the case is similar within the same distance from the equator; those of different years near the latter differ very little, but the differences increase as the latitudes approach the poles. The temperature of the atmosphere likewise diminishes gradually in proportion to its height above the level of the sea.

Mr. Kirwan shews that the rate of diminution depends upon the precise temperature of the surface of the earth where an experiment is made.

This gradual approach to cold, demonstrates that at a certain height eternal congelation must prevail; that height varies of course according to the latitude of the place, being highest at the equator and gradually descending on approaching the poles, it is also lower in the winter. The cold on the summit of Pinchinca was found by M. Bouguer to extend, every morning previous to the rising of the sun, from seven to nine below the freezing point, from which he conjectured, that the mean height of the term of congelation (or that region where water congeals on some part of every day in the year) between the tropics, is 15,577 feet above the level of the sea; in latitude 28 deg. he supposes it to be 43,440 during summer. Taking the difference between the freezing point and the temperature of the equator, it appears, that it bears the same proportion to the term of congelation at the equator that the difference the mean between temperature of any other degree of latitude, and the freezing point, bears to the term of congelation in that latitude.

Estimating the diminution from this method, we find that heat lessens in an arithmetical progression: and from the same premises it may be concluded, that the warmth of the air at some distance from the earth is not to be attri-

buted to the raising of heated strata of air from the earth's surface, but to the conducting power of the air.

The upper strata of the atmosphere are frequently warmer in winter than the lower, and the preceding rule is applicable to the temperature of the air during the summer months only. According to the Philosophical Transactions for 1777, a thermometer placed on the summit of Arthur's Seat, the 31st of January, the year before, stood six degrees higher than a second at Hawk's Hill, situated 684 feet below it: this superior heat is considered by Mr. Kirwan to be produced by a current of heated air flowing from the equator towards the north pole during our winter.

It has been a generally received opinion, that the southern hemisphere, beyond the 40th degree of latitude, is much colder than the corresponding parts of the northern: this is true only with respect to the summer of the former; but the winter in the same latitude is milder than in the latter.

Inconsiderable seas, in temperate and cold climates, are colder in winter and warmer in summer than the standard ocean, as they are necessarily under the influence of natural operations from the land, and its temperature.

Continents have a colder atmosphere than islands situated in the same degree of latitude; and countries lying to the windward of the superior classes of mountains, or forests, are warmer than those which are to the leeward. Earth always possessing a certain degree of moisture, has a greater capacity to receive and retain heat than sand or stones; the latter therefore are heated and cooled with more rapidity: it is from this circumstance that the intense heats of Africa and Arabia, and the cold of Terra del Fuego, are derived. The temperature of growing vegetables changes very gradually; but there is a considerable evaporation from them: if these exist in great numbers, and congregated, as in forests, their foliage preventing the rays of the sun from reaching the earth, the immediate atmosphere must be greatly affected by the ascent of chilled vapours.

Air is one of those bodies which have received the name of electric; it not only contains that portion of electricity which seems necessary to the constitution of all terrestrial bodies, but it is liable also to be charged negatively or positively when electricity is abstracted or introduced by means of conducting bodies. These different states must occasion a variety of phenomena, and probably contribute considerably to the various combinations and decompositions continually going on in air. Professor Beccaria, of Turin, found the air almost always positively electrical, especially in the day-time and in dry weather. When the dark or wet weather clears up, the electricity is always negative. Low thick fogs, rising into dry air, carry up a great deal of electric matter. In the morning, when the hygrometer indicates dryness equal to that of the preceding day, positive electricity obtains even before sunrise. As the sun gets up, this electricity increases more remarkably if the dryness increases. It diminishes in the evening. The mid-day electricity of days equally dry is proportional to the heat. Winds always lessen the electricity of a clear day, especially if damp. For the most part, when there is a clear sky with little wind, a considerable electricity arises after sunset at dew falling.

Air is not only electrified by friction, like other electric bodies, but the state of its electricity is changed by various chemical operations which often go on in the atmosphere. Evaporation seems in all cases to convey electric matter into the atmosphere. On the other hand, when steam is condensed into water, the air becomes negatively electric. Air, when heated, becomes negatively electric, and positively when cooled, even when it is not permitted to expand or contract: and the expansion and contraction of air also occasion changes in its electric state.

As air is an electric, the matter of electricity, when accumulated in any particular strata, will not immediately make its way to the neighbouring strata, but will induce in them changes similar to what is induced upon plates of glass or similar bodies piled upon each other. Therefore, if a stratum of air is electrified positively, the stratum immediately above it will be negative, the stratum above that positive, and so on. Suppose now, that an imperfect conductor were to come into contact with each of these strata: we know from the principles of electricity, that the equilibrium would be restored, and that this would be attended with a loud noise, and with a flash of light. Clouds are imperfect conductors: if a cloud, therefore, comes into contact with two such strata, a thunder-clap will follow. If a positive stratum is situated near the earth, the intervention of a cloud will, by serving as a stepping-stone, bring the stratum within the striking distance, and a thunderclap will be heard while the electrical fluid is discharging itself into the earth. If the stratum is negative, the contrary effects will take place. It does not appear, however, that thunder is often occasioned by a discharge of electric matter from the earth into the atmosphere. The accidents, most of them at least, which were formerly ascribed to this cause, are now much more satisfactorily accounted for by Lord Stanhope's theory of the returning stroke. The discharge from the clouds directly into the earth is also probably less frequent than from cloud to cloud.

The far greater part of the visible phenomena of the atmosphere are due to the water, which, being raised by evaporation, is transported from place to place in vapour, and which, physically speaking, is a proper component part of the air. When, by any means, a portion of this is deprived of its constituent caloric, it reappears in minute drops, which are at first uniformly diffused, and lessen the transparency of the air in proportion to their abundance.

Another meteorological phenomenon that has recently engaged the attention of the scientific, is the formation of dew. As the reader has been referred to this article for an explanation of this phenomenon, we shall here take a brief view of the subject.

The first facts which could lead to the just explanation of this interesting, and, till very lately, inexplicable natural phenomenon, are due to the late Mr. A. Wilson, professor of astronomy in Glasgow, and his son.

Dr. Wilson had previously, in 1781, described the surface of snow, during a clear and calm night, to be 16° colder than air two feet

above it; and in the above paper he shews, that the deposition of dew and hoar-frost is uniformly accompanied with the production of cold. He was the first among philosophical observers who noticed this conjunction. But the different force with which different surfaces project or radiate heat being then unknown, Dr. Wilson could not trace the phenomena of dew up to their ultimate source. This important contribution to science has been lately made by Dr. Wells, in his very ingenious and masterly essay on dew.

1. *Phenomena of Dew.*

Aristotle justly remarked, that dew appears only on calm and clear nights. Dr. Wells shews that very little is ever deposited in opposite circumstances; and *that little* only when the clouds are very high. It is never seen on nights both cloudy and windy; and if in the course of the night the weather, from being serene, should become dark and stormy, dew which had been deposited will disappear. In calm weather, if the sky be partially covered with clouds, more dew will appear than if it were entirely uncovered.

Dew probably begins in the country to appear upon grass, in places shaded from the sun, during clear and calm weather, soon after the heat of the atmosphere has declined, and continues to be deposited through the whole night, and for a little after sunrise. Its quantity will depend in some measure on the proportion of moisture in the atmosphere, and is consequently greater after rain than after a long tract of dry weather; and in Europe, with southerly and westerly winds, than with those which blow from the north and the east. The direction of the sea determines this relation of the winds to dew. For in Egypt, dew is scarcely ever observed except while the northerly or Etesian winds prevail. Hence also dew is generally more abundant in spring and autumn, than in summer. And it is always very copious on those clear nights which are followed by misty mornings, which shew the air to be loaded with moisture. And a clear morning, following a cloudy night, determines a plentiful deposition of the retained vapour. When warmth of atmosphere is compatible with clearness, as is the case in southern latitudes, though seldom in our country, the dew becomes much more copious, because the air then contains more moisture. Dew continues to form with increased copiousness as the night advances, from the increased refrigeration of the ground.

2. *On the cause of Dew.*

Dew, according to Aristotle, is a species of rain, formed in the lower atmosphere, in consequence of its moisture being condensed by the cold of the night into minute drops. Opinions of this kind, says Dr. Wells, are still entertained by many persons, among whom is the very ingenious Professor Leslie. (*Relat. of Heat and Moisture*, pp. 37, and 132.) A fact, however, first taken notice of by Gersten, who published his treatise on dew in 1773, proves them to be erroneous for he found that bodies a little elevated in the air often become moist with dew, while similar bodies, lying on the ground, remain dry, though necessarily, from their position, *as* liable to be wetted, by whatever falls from the heavens, as the former.

After a long period of drought, when the air was very still and the sky serene, Dr. Wells exposed to the sky, 28 minutes before sunset, previously weighed parcels of wool and swandown, upon a smooth, unpainted, and perfectly dry fir table, 5 feet long, 3 broad, and nearly 3 in height, which had been placed an hour before, in the sunshine, in a large level grass-field. The wool, 12 minutes after sunset, was found to be 14° colder than the air, and to have acquired no weight. The swandown, the quantity of which was much greater than that of the wool, was at the same time 13° colder than the air, and was also without any additional weight. In 20 minutes more, the swandown was $14\frac{1}{2}$° colder than the neighbouring air, and was still without any increase of its weight. At the same time the grass was 15° colder than the air four feet above the ground.

Dr. Wells, by a copious induction of facts, derived from observation and experiment, establishes this proposition, *that bodies become colder than the neighbouring air* BEFORE *they are dewed.* The cold therefore which Dr. Wilson and Mr. Six conjectured to be the effect of dew, now appears to be its cause. But what makes the terrestrial surface colder than the atmosphere? The radiation or projection of heat into free space. Now the researches of Professor Leslie and Count Rumford have demonstrated, that different bodies project heat with very different degrees of force.

In the operation of this principle, therefore, conjoined with the power of a concave mirror of cloud, or any other awning, to reflect or throw down again those calorific emanations which would be dissipated in a clear sky, we shall find a solution of the most mysterious phenomena of dew. Two circumstances must here be considered:—

1. The exposure of the particular surface to be dewed, to the free aspect of the sky.

2. The peculiar radiating power of the surface. 1. Whatever diminishes the view of the sky, as seen from the exposed body, obstructs the depression of its temperature, and occasions the quantity of dew formed upon it to be less than would have occurred, if the exposure to the sky had been complete.

Dr. Wells bent a sheet of pasteboard into the shape of a penthouse, making the angle of flexure 90 degrees, and leaving both ends open. This was placed one evening with its ridge uppermost, upon a grass plat in the direction of the wind, as well as this could be ascertained. He then laid 10 grains of white, and moderately fine wool, not artificially dried, on the middle part of that spot of the grass which was sheltered by the roof, and the same quantity on another part of the grass-plat, fully exposed to the sky. In the morning the sheltered wool was found to have increased in weight only 2 grains, but that which had been exposed to the sky 16 grains. He varied the experiment on the same night, by placing upright on the grass-plat a hollow cylinder of baked clay, 1 foot diameter, and $2\frac{1}{2}$ feet high. On the grass round the outer edge of the cylinder, were laid 10 grains of wool, which in this situation, as there was not the least wind would have received as much rain as a like quantity of wool fully exposed to the sky. But the quantity of moisture acquired by the wool

partially screened by the cylinder from the *aspect* of the sky, was only about 2 grains, while that acquired by the same quantity fully exposed, was 16 grains. Repose of a body seems necessary to its acquiring its utmost coolness, and a full deposite of dew. Gravel walks and pavements project heat, and acquire dew, less readily than a grassy surface. Hence wool placed on the former has its temperature less depressed than on the latter, and therefore is less bedewed. Nor does the wool here attract moisture by capillary action on the grass, for the same effect happens if it be placed in a saucer. Nor is it by hydrometric attraction; for in a cloudy night, wool placed on an elevated board acquired scarcely any increase of weight.

If wool be insulated a few feet from the ground on a bad conductor of heat, as a board, it will become still colder than when in contact with the earth, and acquire fully more dew than on the grass. Glass projects heat rapidly, and is as rapidly coated with dew. But bright metals attract dew much less powerfully than other bodies. If we coat a piece of glass, partially, with bright tin-foil, or silver leaf, the uncovered portion of the glass quickly becomes cold by radiation, on exposure to a clear nocturnal sky, and acquires moisture; which, beginning on those parts most remote from the metal, gradually approaches it. Gold, silver, copper, and tin, bad radiators of heat, and excellent conductors, acquire dew with greater difficulty than platina, which is a more imperfect conductor; or than lead, zinc, and steel, which are better radiators. Hence dew which has formed upon a metal will often disappear, while other substances in the neighbourhood remain wet; and a metal, purposely moistened, will become dry, while neighbouring bodies are acquiring moisture. This repulsion of dew is communicated by metals to bodies in contact with, or near them. Wool laid on metal acquires less dew than wool laid on the contiguous grass.

When, during a clear and still night, different thermometers, placed in different situations, were examined at the same time, those which were situated where most dew was formed, were always found to be the lowest. On dewy nights the temperature of the earth, half an inch or an inch beneath the surface, is always found much warmer than the grass upon it, or the air above it. The differences on five such nights, were from 12 to 16 degrees.

In making experiments with thermometers, it is necessary to coat their bulbs with silver or gold leaf, otherwise the glassy surface indicates a lower temperature than that of the air, or the metallic plate it touches. Insulated bodies, or prominent points, are sooner covered with hoar-frost and dew than others; because the equilibrium of their temperature is more difficult to be restored. As aerial stillness is necessary to the cooling effect of radiation, we can understand why the hurtful effects of cold, heavy fogs, and dews, occur chiefly in hollow and confined places, and less frequently on hills. In like manner, the leaves of trees often remain dry throughout the night, while the blades of grass are covered with dew.

No direct experiments can be made to ascertain the manner in which clouds prevent or lessen the appearance of a cold at night, upon the surface of the earth, greater than that of the atmosphere. But it may be concluded from the preceding observations, that they produce this effect almost entirely by radiating heat to the earth, in return for that which they intercept in its progress from the earth towards the heavens. The heat extricated by the condensation of transparent vapour into cloud must soon be dissipated; whereas, the effect of greatly lessening, or preventing altogether, the appearance of a greater cold on the earth than that of the air, will be produced by a cloudy sky during the whole of a long night.

We can thus explain, in a more satisfactory manner than has usually been done, the sudden warmth that is felt in winter, when a fleece of clouds supervenes in clear frosty weather. Chemists ascribed this sudden and powerful change to the disengagement of the latent heat of the condensed vapours; but Dr. Wells's thermometric observations on the sudden alternations of temperature by cloud and clearness, render that opinion untenable. We find the atmosphere itself, indeed, at moderate elevations, of pretty uniform temperature, while bodies at the surface of the ground suffer great variations in *their* temperature. This single fact is fatal to the hypothesis derived from the doctrines of latent heat.—"I had often," says Dr. Wells, "smiled, in the pride of half knowledge, at the means frequently employed by gardeners to protect tender plants from cold, as it appeared to me impossible that a thin mat, or any such flimsy substance, could prevent them from attaining the temperature of the atmosphere, by which alone I thought them liable to be injured. But when I had learned, that bodies on the surface of the earth become, during a still and serene night, colder than the atmosphere, by radiating their heat to the heavens, I perceived immediately a just reason for the practice which I had before deemed useless. Being desirous, however, of acquiring some precise information on this subject, I fixed, perpendicularly, in the earth of a grass-plat, four small sticks, and over their upper extremities, which were six inches above the grass, and formed the corners of a square whose sides were two feet long, I drew tightly a very thin cambric handkerchief. In this disposition of things, therefore, nothing existed to prevent the free passage of air from the exposed grass to that which was sheltered, except the four small sticks, and there was no substance to radiate downwards to the latter grass, except the cambric handkerchief."

The sheltered grass, however, was found nearly of the same temperature as the air, while the unsheltered was 5° or more colder. One night the fully exposed grass was 11° colder than the air; but the sheltered grass was only 3° colder. Hence we see the power of a very slight awning, to avert or lessen the injurious coldness of the ground. To have the full advantage of such protection from the chill aspect of the sky, the covering should not touch the subjacent bodies. Garden walls act partly on the same principle. Snow screens plants from this chilling radiation.

From this rapid emission of heat from the surface of the ground, we can now explain the formation of ice during the night in Bengal,

while the temperature of the air is above 32°. The nights most favourable for this effect, are those which are the calmest and most serene, and on which the air is so dry as to deposit little dew after midnight. Clouds and frequent changes of wind are certain preventives of congelation. Three hundred persons are employed in this operation at one place. The enclosures formed on the ground are four or five feet wide, and have walls only four inches high. In these enclosures, previously bedded with *dry* straw, broad, shallow, unglazed earthen pans are set, containing *unboiled pump-water.* Wind, which so greatly promotes evaporation, prevents the freezing altogether, and dew forms in a greater or less degree during the whole of the nights most productive of ice. If evaporation were concerned in the congelation, wetting the straw would promote it. Moist straw both conducts heat and raises vapour from the ground, so as to obstruct the congelation.

To dew succeed various definite aggregates under the name of cloud. Out of the latter are formed rain, snow, and hail, by which the product of evaporation is finally restored to the earth. The excess for any given time, of the falling water over that which is evaporated, passes off by the springs and rivers to that grand reservoir which forms the far greater part of the surface of the globe. Tracts of forest, especially if mountainous, invite the rain, and protect the springs; while the accumulated heat on cultivated plains often causes the clouds to pass over them, or to be dissipated.

The quantity of rain taken at an annual mean, is the greatest at the equator, and it decreases gradually to the poles; but there are fewer days of rain there, the number of which increase in proportion to the distance from it. From north latitude 12 deg. to 43 deg. the mean number of rainy days is 78; from 43 deg. to 46 deg. the mean number is 103; from 46 deg. to 50 deg. 134: and from 51 deg. to 60 deg. 161. Winter often produces a greater number of rainy days than summer, though the quantity of rain is more considerable in the latter than in the former season. Mountainous districts are subject to great falls of rains, among the Andes particularly, it rains almost incessantly; while the flat country of Egypt is consumed by endless drought. The rain-guage affords reason to suppose, that a greater quantity of rain falls in the lower strata of the atmosphere than in those above, which may be accounted for by the drops attracting vapour in their near approach to the earth. Mr. Copland, of Dumfries, has however discovered the rain collected in the lower guage was greatest when it continued falling for some time, and that the greatest quantity was collected in the higher during short rains, or at the conclusion of lengthened ones.

As rain is known to fall at all hours of the day and night, and at every season of the year, it is apparent that it is caused by operations which prevail eternally, and without defined interruption. The mean annual quantity of rain for the whole globe has been calculated to be about 34 inches. The superficies of the globe consists of 170,981,012 square miles, or 686,401,498,171,475,200 square inches; the quantity of rain, therefore, falling annually, will amount to 23,337,650,812,030,156,800 cubic inches, or somewhat more than 91,751 cubic miles of water. There are 52,745.253 square miles of dry land on the globe; consequently the annual amount of the quantity of rain descending upon it will be 30,960 cubic miles. The sea is supposed to receive 13,140 cubic miles of water, which flow into it annually; therefore it must supply an equal quantity by evaporation. Mr. Dalton estimates the quantity of rain falling in England at 31 inches.

Snow is formed by a process of regular crystallization among the minute frozen particles of water floating in the air. Previous to and during the fall of snow in quantity, the temperature continues about 32 deg. It should seem that the evolution of the constituent caloric of the water produces the same effect when ice is formed in the atmosphere, as when it is formed in water. The structure of a crystal of snow demonstrates that a drop of rain is also formed by the union of a great number of smaller drops. When these come together in the act of freezing, and suddenly, they form a nucleus of white spongy ice, which, by its extreme coldness, become incrusted with clear ice from the water it collects in its descent, constitutes hail as we usually see it. Sometimes, however, the nucleus falls unincrusted, which is a prognostic of sharp frosts. Hail has been likewise observed perfectly transparent, and having the form of an oblate spheroid, showing that it consisted of drops which had been frozen entire in falling with a rotatory motion.

The forms assumed by the suspended water in the interval between the first precipation and the descent of rain, afford a copious field of observation. These are not, as might be hastily supposed, the sport of winds, changing with every movement of the containing medium. Indeed the atmosphere, at the height where the clouds usually appear, is undisturbed by the various obstacles which throw it into contending streams and eddies near the surface of the earth, and flows in a more direct and even current. Accordingly, the particles of water which it contains are allowed to assume a certain arrangement; and constitute a form, which is often equally well defined at a distance with that of solids, although, were we to penetrate it, we should perceive only the grey mist.

As this most interesting part of the subject has been already treated of under the article *cloud,* we shall not here repeat it, but refer the reader to that article, in which he will find a description of the various modifications of suspended vapour exhibited in plate XXXIII.

Among the more modern works on the subject of meteorology, the best that has come under our notice is that of Mr. Daniell, who sums up the leading facts of the science in the following propositions.

1. The mean height of the barometer at the level of the sea is the same in every part of the globe.

2. The barometer constantly descends in a geometrical progression, for equal ascents in the atmosphere subject to a correction for the decreasing temperature of the elevation.

3. The mean temperature of the earth's surface increases gradually from the poles to the equator.

4. The mean temperature of the atmosphere decreases from below upwards in a regular gradation.

The fact is sufficiently established by numerous observations. Mr. Dalton was the first to demonstrate the natural equilibrium of heat in an atmosphere, is when an atom of air, in the same perpendicular column, is possessed of the same quantity of heat, and consequently that an equilibrium results when the temperature gradually diminishes in ascending. This the natural consequence of the increased capacity for heat derived from rarefaction.

5. The barometer at the level of the sea but very slightly affected by the annual or diurnal fluctuations of temperature.

6. The barometer in the higher regions of the atmosphere is greatly affected by the annual and diurnal fluctuations of temperature.

This observation is easily confirmed in various ways, but it is sufficient to refer for its correctness to those valuable registers which are simultaneously kept at Geneva and the summit of Mount St. Bernard.

7. The heating and cooling of the atmosphere by the changes of day and night, take place equally throughout its mass. This is fully established by the same series of observations.

8. The average quantity of vapour in the atmosphere decreases from below upwards, and from the equator to the poles. This consequence is obviously derivable from the preceding laws of temperature, and is moreover amply confirmed by experiment.

9. The condensation of elastic vapour into cloud raises the temperature of the air.

In confirmation of this theoretical and practical conclusion, the observation of M. De Luc may be adduced.

10. Another remarkable phenomenon is, that there exists a general tendency in the wind to blow from north to east, and south-east towards the equator in latitudes below 30°.

11. While the trade wind blows upon the surface of the earth, a current flows in the contrary direction at a great elevation in the atmosphere

This necessary consequence of the theory of the trade-winds, rested for a long time upon theoretical conclusions only; the eruption, however, of the volcano in the Island of St. Vincent, in the year 1812, placed the fact beyond dispute. The Island of Barbadoes is situated considerably to the east of St. Vincent, and between the two the trade wind continually blows, and with such force that it is with considerable difficulty, and only by making a very long circuit that a ship can sail from the latter to the former; notwithstanding this, during the eruption at St. Vincent, dense clouds were formed at a great height in the atmosphere above Barbadoes, and a vast profusion of ashes fell upon the Island. This apparent transportation of matter against the wind caused the utmost astonishment amongst the inhabitants, and the certainty of the fact cannot but be considered as of the utmost interest to the science of meteorology.

12 The mean height of the barometer is not effected by the trade winds.

This is a proof that the quantity of air which passes below from the poles to the equator, must be exactly balanced by an equal quantity flowing above in the opposite direction.

13. Between the latitudes 30° and 40°, both in the northern and southern hemispheres, westerly winds prevail.

14. The western coasts of the extratropical continents have a much higher mean temperature than the eastern coasts.

This difference is extremely striking between the western coast of North America, and the opposite eastern coast of Asia. It is explained by the heat evolved in the condensation of vapour swept from the surface of the

that it arrives upon the eastern coasts is extremely dry; as it moves onwards it bears before it the humid atmosphere of the intermediate seas, and arrives upon the opposite shores in a state of saturation. Great part of the vapour is there at once precipitated, and the temperature of the climate raised by the evolution of its latent heat.

15. A wind generally sets from the sea to the land during the day, and from the land to the sea during the night, especially in hot climates.

The land and sea breezes are amongst the most constant of the phenomena of the inconstant subject with which we are occupied; the land becomes much more heated by the action of the sun's rays than the adjacent water; and the incumbent atmosphere is proportionably rarefied: during the day therefore the dense air of the ocean rushes to displace that of the land; at night, on the contrary, the deep water cools much more slowly than the land, and the reverse action takes place as these changes proceed gradually. The height of the barometer is not affected by them.

16. The trade winds in the neighbourhood of the western coasts of the large continents in their course have their direction changed.

This is an effect of the same nature as that of the land and sea breezes. Those parts of Africa and America, which lie between the tropics, become intensely heated by the action of a vertical sun: the columns of the atmosphere which rest upon them must therefore be highly rarefied, and the more temperate air of the surrounding seas will press upon them. This influence is so decided as to overcome the tendency of the east wind; and on the western coasts of both continents a wind from the west prevails. This is again an instance of a complete perpendicular change from a permanent cause, and the total pressure is unaffected.

Of the same nature are the monsoons of the Indian Ocean and other periodical winds: they are occasioned by a particular distribution of land and water, acted upon by the periodical changes of the sun's declination. While the sun is vertical to the places where they occur, the land becomes heated, and the air expanded, and the wind flows towards the coasts as the sun retires towards the opposite point of its course; the land cools faster than the surrounding seas, and the course of the wind is westward, the simplest way of regarding the sun's motion in declination, as affecting the temperature of the various latitudes, is to suppose a motion of the whole system; by which the line of greatest heat, and the two points of greatest cold, maintaining their relative distances, vibrate on either side of the earth's equa-

tor and poles. None of these changes affect the barometer.

17. Rain seldom occurs in the constant trade winds, but abundantly and constantly in the adjoining latitudes.

Between the tropics the elasticity of the aqueous vapour reaches its maximum amount, and within these limits only, rises to any extent into the upper current of the atmosphere. Its own force, which is laterally exerted, is assisted by the equatorial wind, and it flows to the north and south as fast as it rises within the zone, no accumulation can therefore be formed, and the temperature being remarkably steady, seldom varying more than two or three degrees, precipitation can but seldom occur.

The continental parts, however, of the same regions being liable to greater vicissitudes of heat, are subject to rainy seasons, which are periodical, like the monsoons of the same climates, and are governed as they are by the progress of the sun in declination. The condensation, while it lasts, is in proportion to the density of the vapours, and is violent beyond any thing that is known in temperate climates. The alternate seasons of fine weather are distinguished by cloudless skies and perfect serenity. The extra tropical latitudes, on the contrary, beyond the bounds of the trade winds, are at all times exposed to great precipitations; the vapour in its course is subjected to a rapidly decreasing temperature, and the condensation is fed by a constant supply. We are thus led to the consideration of a temperate zone and a variable climate.

18. Between the tropics the fluctuations of the barometer do not much exceed ¼ of an inch, while beyond this space they reach to three inches.

19. In the temperate climates the rains and the winds are variable.

20. As we advance towards the polar regions we find the irregularities of the wind increased, and storms and calms repeatedly alternate, without warning or progression.

The extremes of heat and cold will sometimes prevail within a very limited compass; and forcible winds will blow in one place, when at the distance of a few leagues gentle breezes prevail. Ships within the circle of the horizon may be seen enduring every variety of wind and weather at the same moment; some under close reefed top-sails labouring under the force of a storm; some becalmed, and tossing about by the violence of the waves, and others plying under gentle breezes, from quarters as diverse as the cardinal points. The fluctuations of the barometer are also great and sudden, proving that theory would have induced us to conclude that the irregularities of these regions extend to the higher strata of the atmosphere.

21. In the extra tropical climates a fall in the barometer almost always precedes a fall of rain, and indicates an acceleration or change of the aerial currents.

22. Barometers situated at great distances from each other often rise and fall together with great regularity.

23. More than two currents may often be traced in the atmosphere at one time by the motions of the clouds, &c.

24. The force of the winds does not always decrease as the elevation increases, but, on the contrary, is often found to augment rapidly.

25. The variations of the barometer are less in high situations than in those at the level of the sea.

26. In Great Britain, upon an average of ten years, westerly winds exceed the easterly in the proportion of 225 to 140.

Of those from the east the northerly exceed the southerly in the proportion of about 74 to 54; leaving but a very small proportion indeed which blow from the most irregular point, *viz.* the south east.

27. Upon the same average the northerly winds are to the southerly, 192 to 173.

28. Northerly winds almost invariably raise the barometer, while southerly as constantly depress it.

29. The most permanent rains of this climate come from the southerly regions.

30. The mean height of the barometer varies but little with the changes of the seasons.

31. The elasticity of the aqueous vapour does not decrease gradually as we ascend in the atmosphere, in proportion to the gradual decrease of the temperature and density of air: but the dew point remains stationary to great heights, and then suddenly falls to a large amount.

32. The tension of vapour given of in the process of evaporation is determined, not by the temperature of the evaporating surface, but by the elasticity of the aqueous atmosphere already existing.

33. The apparent permanency and stationary aspect of a cloud is often an optical deception arising from the solution of moisture on one side of a given point, as it is precipitated on the other.

34. The quantity of vapour in the atmosphere, in the different seasons of the year (measured on the surface of the earth, and near the level of the sea,) follows the progress of the mean temperature.

35. The pressure of the aqueous atmosphere, separated from that of the aerial, generally exhibits directly opposite changes to the latter.

36. Great falls of the barometer are generally accompanied by a temperature above the mean for the season, and great rises by one below the same. That the different phases of the moon have some connexion with changes in the atmosphere, is an opinion so universal and popular as to be on that account alone entitled to attention. No observation is more general, and on no occasion perhaps is the almanac so frequently consulted as in forming conjectures upon the state of the weather. The common remark, however, goes no further than that changes from wet to dry, and from dry to wet, generally happen at the changes of the moon. When to this result of universal experience we add the philosophical reasons for the existence of tides in the aerial ocean, we cannot doubt that such a connexion exists. The subject however, is involved in much obscurity.

This article having already become too protracted we cannot enter on any description of the instruments used in the science of meteorology; we shall therefore simply mention the most essential of these, some of which will be found described in other parts of this work

The changes to which the atmosphere is most subject are its *temperature*, *weight*, *moisture*, and *electricity*; and the instruments by which these are respectively measured are the ***thermometer***, ***barometer***, ***hygrometer***, and ***electrometer***. The result of these changes is in some cases *wind*, and in others rain or snow, which have also been subjected to measurement; the intensity of the former by ***anemometer***, and the quantity of the latter by the *pluviometer*, or *rain-guage*. It may be proper to observe that these instruments should be of the very best construction, otherwise the results of observations made with them cannot be depended on.

METHOD, in logic, &c. the arrangement of our ideas in such a regular order, that their mutual connection and dependence may be readily comprehended.

METHODISTS. The term Methodist was first given to Themison, the founder of a sect of physicians at Rome, which flourished about three hundred years, and had some of the greatest physicians of the age among its members.

In the seventeenth century there sprung up a new species of polemic doctors, who were denominated Methodists, and distinguished themselves by their zeal and dexterity in defending the church of Rome against the attacks of the Protestants. This sect is now no more; and the appellation is made to designate the followers of the late Messrs. John and Charles Wesley, and the societies founded by the Rev. George Whitefield. They are divided into Whitefieldian and Wesleyan Methodists. The members of the former division embrace the doctrines of Calvin; the latter, as far as relates to free-will, are Arminians.

METONYMY, in rhetoric, is a trope in which one name is put for another, on account of the near relation there is between them. By this trope any of the most significant circumstances of a thing are put for the thing itself. See RHETORIC.

METOPE. See ARCHITECTURE.

METRE, in poetry. See HEXAMETER, PENTAMETER, &c.

MEZEREON. See DAPHNE.

MEZZOTINTO. See ENGRAVING.

MIASMA, among physicians, denotes the contagious effluvia of pestilential diseases, whereby they are communicated to people at a distance

MICA. This stone forms an essential part of many mountains, and has been long known under the names of glacies Mariæ, and Muscovy glass. It consists of a great number of thin laminæ adhering to each other, sometimes of a very large size. Specimens have been found in Siberia nearly 2½ yards square.

Its texture is foliated. Its fragments flat. The lamellæ flexible, and somewhat elastic. Very tough. Often absorbs water. Specific gravity from 2.6546 to 2.9342. Feels smooth, but not greasy. Powder feels greasy. Colour, when purest, silver white or grey; but it occurs also yellow, greenish, reddish-brown, and black. Mica is fusible by the blowpipe into a white, grey, green, or black enamel; and this last is attracted by the magnet.

Mica has long been employed as a substitute for glass. A great quantity of it is said to be used in the Russian marine for panes to the cabin-windows of ships. It is also used in our navy for lantherns, for the use of the powder-rooms,

MICROMETER. An astronomical machine, which, by means of a screw serves to measure extremely small distances in the heavens, &c. and that to a great degree of accuracy.

The micrometer consists of a graduated circle, plate XXVI, fig 7, of a screw *q o*, and its index *q r*. The threads of the screw are such, that 50 make the length of one inch exactly. When it is to be used, the point *o* is set to the side of the part to be measured, and then the index is turned about with the finger, till the eye perceives the point has just passed over the diameter of that part; then the number of turns, and parts of a turn, shewn by the graduated circle, will give the dimensions in parts of an inch, as we shall show by the following example: Suppose it is required to measure the diameter of a human hair, and I observe the index is turned just once round while the point *o* passes over it; then it is plain the diameter of the hair in the image is $\frac{1}{50}$th of an inch. Now if the microscope, I D E F, *d e f*, magnifies 6 times, or makes the image 6 times larger in diameter than the object, then is the diameter of the hair itself but $\frac{1}{6}$th of $\frac{4}{50}$, that is, but $\frac{1}{300}$th, part of an inch.

Also it is to be observed, that as there are ten large divisions, and twenty small ones, on the micrometer plate, so each of those small divisions is the $\frac{1}{20}$th of $\frac{1}{50}$th, or the $\frac{1}{1000}$th part of an inch. Therefore, if, in measuring any part of an object, you observe how many of these smaller divisions are passed over by the index, you will have so many thousandth parts of an inch for the measure required.

There have been micrometers contrived by various persons. We shall describe one invented by Mr. Cavallo, which consists of a small semitransparent scale or slip of mother-of-pearl, about the 20th part of an inch broad, and of the thickness of common writing paper. It is divided into a number of equal parts by means of parallel lines. The micrometer is situated within the tube, at the focus of the eye-lens of the telescope, where the image of the object is formed, and with its divided edge passing through the centre of the field of view. It is to be fixed upon the diaphragm, which generally stands within the tube at the focal distance of the eye-lens.

By looking through the telescope, the image of the object and the micrometer will appear to coincide; hence the observer may easily see how many divisions of the latter measure the length or breadth of the former; and knowing the value of the divisions of the micrometer, he may easily determine the angle which is subtended by the object.

MICROSCOPE. See OPTICS.

MIDWIFERY, in the restricted sense of the word, is the art of assisting women in childbirth. It is generally, however made to comprehend the management of women, both

previous to, and some time after, delivery; as well as the treatment of the infant in its early state

The nature of this subject is such that no abridgment of it could convey an adequate idea of it, particularly without plates; and as we do not expect that the *experienced accoucheur* will open our little volume for the purpose of obtaining information, we should deem it worse then a waste of time to gratify the idle curiosity of such as have no real use for information on a subject of such extreme delicacy.

MIGRATION, *of birds.* It has been generally believed, that many different kinds of birds annually pass from one country to another, and spend the summer or the winter where it is most agreeable to them: and that even the birds of our own island will seek the most distant southern regions of Africa, when directed by a peculiar instinct to leave their own country. It has long been an opinion pretty generally received, that swallows reside during the winter season in the warm southern regions; and Mr. Adamson particularly relates his having seen them at Senegal, when they were obliged to leave this country. But besides the swallow, Mr. Pennant enumerates many other birds which migrate from Britain at different times of the year, and are then to be found in other countries; after which they again leave these countries, and return to Britain.

These are the hooded crow, the cuckoo, the wryneck, the hoopoe, grouse, ring-doves, turtle-doves, the stare, thrushes, chatterers, grosbeaks, buntings, finches, larks, fly-catchers, wagtails, warblers, nightingales, black-caps, willow-wrens, white-ears, white-throats, goatsuckers, several kinds of water-fowl, such as herons, curlews, snipes, sandpipers, plovers, oyster-catchers, rails, phalaropes, grebes, avosets, auks, divers, tem, petrels, mergansers, several species of ducks, and corvorants.

MILE, a measure of length or distance, containing eight furlongs.

The English, statute-mile is four-score chains, or 1760 yards; that is 5280 feet. See CHAIN, YARD, and FOOT.

The following is a list of the itinerary measures of some of the principal European nations in English yards.

	English Yards.
Arabian Mile	2148
Bohemian Mile	10137
Chinese Lis	629
Danish Mile	8244
Dutch Mile	6395
English Mile	1760
Flemish Mile	6869
German Miles, long	10126
German Miles, short	6859
Hamburg Mile	8244
Irish Mile	3038
Italian Mile	2025
Oldenburgh Mile	10820
Portuguese Legoas	6760
Prussian Miles	8468
Russian Versts	1167
Scotch Miles	1984
Spanish Leguas, common	7416
Spanish Leguas, legal	4635
Turkey Berries	1826
Westphalian Miles	12151

MILIARY FEVER, a malignant fever, so called from the eruption of certain pustules resembling millet-seeds. See MEDICINE.

MILIUM, MILLET, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the 4th order, gramina. The calyx is bivalved and uniflorous; the corolla is very short: the stigmata pencil-like. There are 12 species, of which the most remarkable is the effusum, or common millet.

MILK, is a fluid secreted by the female of all those animals denominated mammalia, and intended evidently for the nourishment of her offspring.

The milk of every animal has certain peculiarities which distinguish it from every other milk. But the animal whose milk is most made use of by men as an article of food, and with which, consequently, we are best acquainted, is the cow. Chemists, therefore, have made choice of cows' milk for their experiments.

Milk is an opaque fluid, of a white colour, a slight peculiar smell, and a pleasant sweetish taste. When newly drawn from the cow, it has a taste very different form that which it acquires after it has been kept for some hours.

When milk is allowed to remain at rest, it separates into a thick white fluid, called cream, which collects on the surface, and the fluid beneath which is more watery. The quantity of cream obtained from milk, and the time it requires to separate, vary according to the nature of the milk, and the temperature of the atmosphere. When the milk is allowed to stand after the spontaneous separation of the cream, it first becomes acescent, and then coagulates. When the coagulum is pressed gently, a serous fluid is forced out, and the remainder is the caseous part or pure cheese. Butter and cheese are obtained artificially: the former by the operation of churning, and the milk which remains after the butter has been separated, or, as it is called the butter-milk, has all the properties of milk from which the cream has been separated. Cheese is obtained by the addition of rennet to the milk, which is prepared by digesting the inner coat of the stomach of young sucking animals, especially that of the calf. The quality of cheese depends upon the quantity of cream remaining in the milk. The best cheese is obtained by coagulating the milk at the temperature of 100°, and expressing the whey slowly and gradually, without breaking down the curd. Whey expressed from coagulated milk, if boiled, and the whole curd precipitated becomes transparant and colourless. By slow evaporation it deposits crystal of sugar, with some muriate of pot-ash, muriate of soda, and phosphate of lime. The liquid which remains after the separation of the salts, is converted by cooling, into a gelatinous substance If whey be kept it becomes sour by the formation of the lactic acid, and it is to this that the spontaneous coagulation of milk is owing. Milk may, after it is sour, be fermented, and it will yield a vinous intoxicating liquor. Milk is likewise susceptible of the acetous fermentation. The constituent parts which enter into the composition of milk, are water, oil, curd, gelatine, sugar of milk, muriate of soda, muriate of potash, phosphate of lime, and sulphur

The milk of different animals is composed of nearly the same substances; but the proportions vary so much, as to give them very different properties. Every kind of milk produces cream. In that of the cow it is copious, thick, and yellow. In woman's milk the quantity is small, and it is white and more liquid. Goat's milk produces abundance, and it is thicker and whiter than that from the cow. Ewe's milk produces as much as that of the cow, and of nearly the same colour. The cream from asses' milk resembles women's. In mare's milk it is very fluid, and similar in colour and consistence to good cow's milk before the cream appears on the surface. Butter obtained from the milk of the cow differs in colour; but has always much consistency. That from women's milk is small in quantity, insipid, and of a paleyellow. The butter of asses' milk is white, and soft, and disposed to be rancid. That from goat's milk is abundant, white, and soft. That from ewe's milk is yellow and soft: that from mare's milk has little consistence, and is readily decomposed. The caseous part of milk varies in different animals. That from the milk of the cow is bulky, and retains much serum. That from women's milk is small in quantity, has an unctuous feel, and but a small portion of whey. The curd of asses' milk is similar to that of women's, but not unctuous. Curd from the milk of the goat is abundant, of a firmer consistence than that of the cow, and retains less whey. Curd from ewe's milk is fat and viscid: that from mare's milk is very similar to what is obtained from women's milk. The serum, or whey, constitutes a great proportion of the milk. That from the milk of the cow has a greenish cast, and a sweet taste; it contains sugar of milk and neutral salts. The whey from woman's milk has little colour; but contains much saccharine matter. The whey of asses' milk is colourless, and contains less salts and more sugar than that of the cow. Whey of the goat is yellowish, and contains very little sugar and saline matter. The latter is muriate of lime. The whey of ewes' milk is always colourless, and contains the smallest quantity of sugar, and but a small portion of muriate and phosphate of lime. That of mare's milk has little colour, and contains a large proportion of saccharine matter, and of saline substances.

MILKY-WAY, in astronomy, a broad track or path, encompassing the whole heavens, distinguishable by its white appearance, whence it obtains its name.

MILL, a machine or engine for grinding corn, &c. of which there are several kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c. In water-mills, the momentum of the water is the moving power; and the attrition of the two stones in grinding is the force to be overcome. Of these there are two kinds, viz. those where the force of the water is applied above the wheel, and those where it is applied below the wheel; the former being called overshot, and the latter undershot mills: and to these we may add a breast-mill, where the water strikes against the middle of the wheel. Corn is ground by two mill-stones, placed one above the other, without touching. The lower, or nether mill-stone, is immoveable; but the upper one turns upon a spindle. The opposite surfaces of the two stones, which act to grind the corn, are not plane or flat; but the upper one is hollow, and the under one swells upwards, each of them being of a conic figure, whose axis is very short in proportion to the diameter of its base: for the upper one, being six feet in diameter, is hollowed but about one inch at its centre; and the lower one rises but about three-fourths of an inch. These two mill-stones come nearer and nearer towards their circumference, whereby the corn that falls from the hopper has room to insinuate between them as far as two-thirds of the radius, which is the place where it begins to be ground, and where it makes the greatest resistance that it is capable of; the space between the stones being in that place but about two-thirds or three-fourths of the thickness of a grain of corn. But as the millers have the means of raising or sinking the upper stone a little, they can proportion its distance from the lower one, according as they would have the flour finer or coarser. The circular motion of the upper mill-stone brings the corn out of the hopper by jerks, and causes it to recede from the centre towards the circumference; where being quite reduced to flour, it is thrown out of the mill, by the centrifugal force of the stone, through a hole provided on purpose. Mr. Smeaton has considered the best methods of constructing all these mills from machines and models made on purpose; but, conscious of the inferiority of models to actual practice, did not venture to give his opinion without having seen them actually tried, and the truth of his doctrines established by practice. Having described the machines and models used for making his experiments, he observes, that, with regard to power, it is most properly measured by the raising of a weight; or, in other words, if the weight raised is multiplied by the height to which it can be raised in a given time, the product is the measure of the power raising it; and, of consequence, all those powers are equal whose products made by such multiplication are equal: for if a power can raise twice the weight to the same height, or the same weight to twice the height, in the same time that another can, the former power will be double the latter; but if a power can only raise half the weight to double the height, or double the weight to half the height, in the same time that another can, the two powers are equal. This, however, must be understood only of a slow and equable motion, without acceleration or retardation.

To compute the effects of water-wheels correctly, it is necessary to know, in the first place, what is the real velocity of the water which impinges on the wheel; 2. The quantity of water expended in a given time; and, 3. How much of the power is lost by the friction of the machinery.

Mr. Smeaton determined, from a variety of experiments, that the mean power of a volume of water 15 inches in height, gave 8.96 feet of velocity in each minute to a wheel on which it impinged. The computation of the power to produce such an effect, allowing the head of water to be 105.8 inches, gave 264.7 pounds of water descending in one minute through the space of 15 inches: therefore 264.7, multiplied by 15, was equal to 3.970. But as that power

is found equal to raising no more than 9.375 pounds to the height of 135 inches, it was manifest that a major part of the power was lost; for the multiplication of these two sums amounted to no more than 1,266; of course the friction was equal to $\frac{3}{4}$ths of the power.

Mr. Smeaton considers the above to be the maximum single effect of water upon an undershot wheel, where the fall is 15 inches. The remainder of power, it is plain, must be equal to that of the velocity of the wheel itself, multiplied into the weight of the water, which in this case brings the true proportion between the power and the effect to be as 3,849 to 1,266; or as 11 to 4.

Where a wheel revolved 86 times in a minute, the velocity of the water must have been equal to 86 circumferences of the wheel; which, according to the dimensions of the apparatus used by Mr. Smeaton, was as 86 to 30, or as 20 to 7. The greatest load with which the wheel would move was 9*lb.* 6*oz.*; by 12 *lb.* it was entirely stopt. From this we are to conclude, as Mr. Smeaton did, that the impulse of the water is more than double what our theory states it to be. This he accounts for by the wheel being placed in a narrow slit; so that the water could not escape but by passing with the wheel's motion; thus giving a multiplied force. Further, when a float-board comes in contact with the water, it receives a certain check, which causes the back, or upper part of the float-board to become loaded with a kind of wane, which accumulates in consequence of the momentary impediment, and consequently adds to the impetus. This added force must ever be in proportion to the depth to which the float-board sinks into the stream; not exceeding its whole depth beyond the rim, or body, of the wheel to which it is attached.

The following conclusions result from the velocities of wheels, as acted upon by different heights of water. 1. The head, or altitude, being the same, the effect will be proportioned to the quantity of water expended; or, in other words, according to the weight and velocity of the impending fluid. 2. The expence or quantity of water being the same, the effect will be nearly in proportion to the height of the head. 3. The quantity of water expended being the same, the effect is nearly as the square of the velocity. 4. The aperture whence the fluid issues being the same, the effect will be nearly as the cube of the velocity. 5. The virtual head, or that from which we calculate the power, bears no proportion to the head-water; but when the aperture is larger, or the velocity of the water less, they approach nearer to a coincidence: consequently in the large openings of mills and sluices, where great quantities of water are discharged from moderate areas, the head of water, and the virtual head (determined from the velocity) will nearly agree, as experience proves. 6. The most general proportion between the power and the effect is as 10 to 3; the extremes are 10 to 3, 2, down to 10, 2, 8. 7. The proportion of velocity between the water and the wheel is usually as 5 to 2. 8. Although we have no certain maximum of the power of a wheel; that is, what it will carry, and no more; we may generally consider the limits to be, that wheels which work freely with 15, will stop when 20 are opposed to their motion: consequently when 3 is the effect, 4 will stop the work.

Mr. Smeaton found, that in undershot-mills, when he reduced the number of floats from 24 to 12, the effect was reduced one-half, because the water escaped between the floats without touching them; but when he added a circular sweep of such length, that before one float-board quitted it another had entered it, he found the former effect nearly restored.

This mode more particularly applies to breast-wheels, or such as receive the water immediately below the level of the axis. In such the circular trough is indispensable; because the water would not communicate the full effect desirable from the joint operations of velocity and weight. In this kind of wheels it is proper that the float-boards should be confined both at their sides and at their extremities, so that the water may accompany all the way from the head down to the lowest part of the wheel, whence it should draw off with sufficient readiness to allow the succeeding fall to supply its place, without being in the least retarded.

The over-shot wheel is by far the most powerful; both because it receives the water at the very commencement of descent, and that the buckets with which this kind of wheel is ordinarily furnished, retain the power until they gradually discharge their contents, as these buckets successively become inferior parts of the circumference. It should be stated in this place, that much may be effected by allowing the water merely to flow upon the upper part of the wheel, into the superior buckets, whereby an immense auxiliary power is erected as they successively become filled. The more slowly any body descends by the force of gravity, while acting upon any piece of machinery, the more of that force will be spent upon it, and consequently the effect will be the greater. Mr. Smeaton found, that when his wheel, which was two feet in diameter, revolved 20 times in a minute, its effect was greatest: when it made only 18½ turns the effect was irregular: and when so laden as not to make 18 turns, the wheel was overpowered by the load. He found that 30 turns in the minute occasioned a loss of about $\frac{1}{20}$th, and that when turned 30 times in a minute, the diminution of effect was nearly one-fourth of its powers. This proportion may be easily estimated on any wheel of greater extent, by computing the proportion of accumulated power lost by greater velocity than may be sufficient to load the wheel by means of the buckets being filled; observing that the progress of a machine may be so much retarded as to cause the effect to be irrelevant of the purpose, although the machine may be kept in motion.

The maximum load for an overshot wheel is that which reduces the circumference of the wheel to its proper velocity, which is known by dividing the effect it ought to produce in a given time by the space intended to be described by the circumference of the wheel in the same time. The quotient will be the resistance overcome at the circumference of the wheel; it is equal to the load required, including the friction and the resistance of the machinery. So much, however, depends on the proper precautions for reducing the friction

of the several moving parts, that too much stress cannot be laid on that highly important consideration.

The following is a description of a corn-mill of the most common sort. See plate XXXIV. AB, fig. 1, is the water-wheel, which is generally from 18 to 24 feet in diameter, reckoned from the outermost edge of any float-board at A, to that of the opposite one at B. The water, striking on the floats of this wheel, drives it round, and gives motion to the mill. The wheel is fixed upon a very strong axis or shaft C, one end of which rests on D, and the other on E, within the mill-house.

On this shaft, or axis, and within the mill-house, is a wheel F, about eight or nine feet in diameter, having cogs all round, which work in the upright staves, or rounds of a trundle G. This trundle is fixed upon a strong iron axis, called the spindle, the lower end of which turns in a brass foot fixed at H, in a horizontal beam H, called the bridge-tree; and the upper end of the spindle turns in a wooden bush fixed into the nether mill-stone, which lies upon beams in the floor I. The top of the spindle above the bush is square, and goes into a square hole in a strong iron cross, *abcd*, fig. 2, called the rynd; under which, and close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time as it does the rynd.

The rynd is let into grooves in the under surface of the running mill-stone K, and so turns it round in the same time that the trundle G is turned round by the cog-wheel F. This mill-stone has a large hole quite through its middle, called the eye of the stone, through which the middle part of the rynd and upper end of the spindle may be seen; whilst the four ends of the rynd lie below the stone in their grooves. One end of the bridge-tree, which supports the spindle, rests upon the wall, whilst the other is let into a beam, called the brayer LM.

The brayer rests in a mortice at L; and the other end M hangs by a strong iron rod N, which goes through the floor I, and has a screw-nut on its top at O; by the turning of which nut, the end M of the brayer is raised or depressed at pleasure; and consequently the bridge-tree and the upper mill-stone. By this means the upper mill-stone may be set as close to the under one, or raised as high from it, as the miller pleases. The nearer the mill-stones are to each other, the finer the corn is ground; and the more remote from one another, the coarser. The upper mill-stone is inclosed in a round box, which does not touch it any where, and is about an inch distant from its edge all round. On the top of this box stands a frame for holding the hopper P, to which is hung the shoe Q, by two lines fastened to the hinder part of it, fixed upon hooks in the hopper, and by one end of the string R fastened to the fore part of it; the other end being twisted round the pin S. As the pin is turned one way, the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and as the pin is turned the other way, it lets down the shoe, and enlarges the aperture.

There is a square hole in the top of the spindle, in which is put the feeder F, fig. 2; this feeder, as the spindle turns round, jogs the shoe three times in each revolution, and so causes the corn to run constantly down from the hopper through the shoe into the eye of the mill-stone, where it falls upon the top of the rynd, and is by the motion of the rynd, and the leather under it thrown below the upper stone, and ground between it and the lower one. The violent motion of the stone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the centre, as in a spiral, in every revolution, until it is quite thrown out, and being then ground, it falls through a spout, called the mill-eye, into a trough placed to receive it.

When the mill is fed too fast, the corn bears up the stone, and is ground too coarse; and, besides, it clogs the mill, so as to make it go too slow. When the mill is too slowly fed, it goes too fast; and the stones, by their attrition, are apt to strike fire. Both these inconveniences are avoided by turning the pin S backward or forward, which draws up or lets down the shoe; and thus regulates the feeding, as the miller sees convenient.

The quantity of power sufficient to turn a heavy mill-stone, is but very little more than what is necessary to turn a light one; for as it is supported upon the spindle by the bridge-tree, and the end of the spindle that turns in the brass foot therein being but small, the difference arising from the weight is but very inconsiderable in its action against the power or force of the water. The spindle of the mill-stone being thus supported, the upper mill-stone is allowed a slight vertical motion, by which movement, the heavier the stones are, the more forcibly is the corn wedged in between them.

In order to cut and grind the corn, both the upper and under mill-stones have channels or furrows cut into them, proceeding obliquely from the centre to the circumference. And these furrows are cut perpendicularly on one side, and obliquely on the other, which gives each furrow a sharp edge; and in the two stones, they come against one another, like the edges of a pair of scissars; and so cut the corn, to make it grind the easier, when it falls upon the places between the furrows.

The grinding surface of the under stone is a little convex from the edge to the centre, and that of the upper stone a little concave; so that they are farthest from one another in the middle, and approach gradually nearer towards the edges. By this means the corn, at its first entrance between the stones, is only bruised; but as it goes farther on towards the circumference or edge, it is cut smaller and smaller; and, at last, finely ground, just before it comes out from between them.

When the furrows become blunt and shallow by wearing, the running-stone must be taken up, and both stones new drest with a chisel and hammer. The bush must embrace the spindle quite close, to prevent any shake in the motion, which would make some parts of the stones grate and fire against each other; whilst the other parts of them would be too far asunder, and by that means spoil the meal. Whenever the spindle wears the bush, so as to begin to shake in it, the stone must be taken up, and a chisel driven into several parts of the bush; and when it is taken out, wooden

wedges must be forced into the holes; by which means the bush will be made to embrace the spindle again, close all round. When any accident of this kind happens, the perpendicular position of the spindle must be restored, by adjusting the bridge-tree with proper wedges put between it and the brayer. It often happens that the rynd is a little wrenched in laying down the upper stone upon it, or is made to sink a little lower on one side of the spindle than on the other. But this is easily rectified, by raising the stone a little with the lever, and putting bits of paper, cards, or thin chips, between the rynd and the stone.

A less quantity of water will turn an overshot-mill (where the wheel has buckets instead of float-boards) than a breast-mill, where the fall of water seldom exceeds half the height of the wheel; so that where there is but a small quantity of water, and a fall great enough for the wheel to lie under it, the bucket, or overshot, wheel, is always used: but where there is a large body of water with a little fall, the breast, or float-board wheel, must be used. Where the water runs only upon a small declivity, it can act but slowly upon the under part of the wheel; in which case, the motion of the wheel will be slow: and therefore the floats ought to be very long, though not high, that a large body of water may act upon them: so that what is wanting in velocity may be made up in power, and then the cog-wheel may have a greater number of cogs, in proportion to the rounds in the trundle, in order to give the mill-stone a sufficient degree of velocity.

It was the opinion of Smeaton, that the powers necessary to produce the same effect on an undershot-wheel, a breast-wheel, and an overshot wheel, must be to each other as the numbers 2.4, 1.75, and 1.

Practical Rules for the Construction of Mills.

Measure the perpendicular height of the fall of water, in feet, above that part of the wheel on which the water begins to act, and call that the height of the fall.

Multiply this constant number 64,2882 by the height of the fall in feet, and the square root of the product will be the velocity of the water at the bottom of the fall, or the number of feet that the water there moves per second.

Divide the velocity of the water by three, and the quotient will be the velocity of the float-boards of the wheel, or the number of feet they must each go through in a second, when the water acts upon them so as to have the greatest power to turn the mill.

Divide the circumference of the wheel in feet by the velocity of its float in feet per second, and the quotient will be the number of seconds in which the wheel turns round.

By this last number of seconds divide 60, and the quotient will be the number of turns of the wheel in a minute.

Divide 120 (the number of revolutions a mill-stone four feet and a half diameter ought to have in a minute) by the number of turns of the wheel in a minute, and the quotient will be the number of turns the mill-stone ought to have for one turn of the wheel. Then, as the number of turns of the wheel in a minute is to the number of turns of the mill-stone in a minute, so must the number of staves in the trundle be to the number of cogs in the wheel, in the nearest whole numbers that can be found.

We shall here add a brief description of a water-mill invented by Dr. Barker, which is extremely simple in its construction, having neither wheel nor trundle. The power of a mill of this nature must obviously depend on the height of the column of water which presses on the horizontal piece at bottom.

This machine is represented by fig. 2, in which, A is a pipe or channel that brings water to the upright tube B. The water runs down the tube, and thence into the horizontal trunk C, and runs out through holes at *d* and *e* near the ends of the trunk on the contrary sides thereof.

The upright spindle D is fixed in the bottom of the trunk, and screwed to it below by the nut *g*; and is fixed into the trunk by two cross bars at *f*: so that, if the tube B and trunk C be turned round, the spindle D will be turned also.

The top of the spindle goes square into the rynd of the upper-mill-stone H, as in common mills; and as the trunk, tube, and spindle turn round, the mill-stone is turned round thereby. The lower, or quiescent mill-stone is represented by I; and K is the floor on which it rests, and wherein is the hole L for letting the metal run through, and fall down into a trough which may be about M. The hoop or case that goes round the mill-stone rests on the floor K, and supports the hopper, in the common way. The lower end of the spindle turns in a hole in the bridge-tree GF, which supports the mill-stone, tube, spindle, and trunk. This tree is moveable on a pin at *h*, and its other end is supported by an iron rod N fixed into it, the top of the rod going through the fixed bracket O, and having a screw nut *o* upon it, above the bracket. By turning this nut forward or backward, the mill-stone is raised or lowered at pleasure.

While the tube B is kept full of water from the pipe A, and the water continues to run out from the ends of the trunk; the upper mill-stone H, together with the trunk, tube, and spindle turns round. But, if the holes in the trunk were stopped, no motion would ensue; even though the tube and trunk were full of water. For, if there were no hole in the trunk, the pressure of the water would be equal against all parts of its sides within. But, when the water has free egress through the holes, its pressure there is entirely removed: and the pressure against the parts of the sides which are opposite to the holes, turns the machine.

The following table, commonly called the mill-wright's table will be found of service to all who have occasion for calculations in machinery.

THE MILLWRIGHT'S TABLE.

Height of the fall of water.	Velocity of the fall of water per second.		Velocity of the wheel per second.		Revolutions of the wheel per minute.		Revolutions of the mill-stone for one of the wheels		Cogs in the wheel, and staves in the trundle.		Revolutions of the mill-stone per minute by these staves and cogs.

To construct a mill by this table, find the height of the fall of water in the first column, and against that height, in the sixth column, you have the number of cogs in the wheel, and staves in the trundle, for causing the mill-stone four feet six inches diameter, to make about 120 revolutions in a minute, as near as possible, when the wheel goes with one-third part of the velocity of the water. And it appears by the 7th column, that the number of cogs in the wheel, and staves in the trundle, are so near the truth for the required purpose, that the least number of revolutions of the mill-stone in a minute is 118, and the greater number never exceeds 121; which is according to the speed of some of the best mills. One of the most usual communications of motion in machinery, is by means of toothed wheels acting on each other. It is of the greatest consequence to have the teeth so formed, that the pressure by which one of them urges the other round its axis is constantly the same. The ends of the teeth should never be formed of parts of circles, but of a particular curve, called the epicycloid, which is formed by moving the circle, called the generating circle, round the circumference of another circle while it turns also round its own centre; then any point will describe an epicycloid.

Emerson observes, that the teeth of wheels ought not to act upon each other before they arrive at the line which joins their centres; and though the inner or under sides of the teeth may be of any form, yet it is better to make both sides alike, which will serve to make the wheel turn backwards. The more teeth that work together the better; at least one tooth should always begin before the other has done working. The teeth ought to be so disposed as not to trouble or hinder one another before they begin to work.

Mills, *wind*, are, in their general construction, much the same as water mills; adverting to the difference of the power by which they are acted upon. The external apparatus consists chiefly of the sails, or vanes, which are commonly four, placed in nearly a vertical position, and giving, as they turn, a rotatory motion to an axis inclining but little from the horizon.

Mills, *copper* and *brass*, are almost invariably worked by water, having large wheels that give immediate action to hammers of great weight; these beat out the large slabs and bricks of metal into various forms, such as kettles, coppers, boilers, &c. and roll out sheets for various purposes, but especially for coppering the bottoms of ships. This process is effected by passing the heated metal between two cast-iron cylinders, of about a foot diameter, which, having contrary motions, draw it through a small interval left between them: and by reducing the thickness, give greater surface to the sheet.

Mills, *silk*, *cotton*, &c. require much delicacy in their construction; their principal movements depend on the same principles as those of the mills described in the plate; the more minute parts, such as the bobins, &c. being moved by means of one or more leather straps passing them in close contact, so as to occasion them to revolve with an astonishing degree of velocity.

Mills, *saw*, though extremely simple in their parts, require the greatest care in their formation. The saws which are moved by cranks, must be set with most scrupulous exactness

In most instances the timber is brought forward to the saw by means of a small toothed wheel, and an axle whereupon the rope that pulls the timber is gradually coiled.

MILLS, *flax*, are generally worked by cattle; their construction is simple; the essential parts being the hackle, which combs the flax; and the scutcher, which strikes it: both tend to clearing away the coarser and unequal fibres, and to prepare the material for being spun either by hand, or by means of machinery.

Having said thus much on the subject of mill-work, we beg leave to refer those of our readers who may be in search of abstruse knowledge, to Olinthus Gregory's work on the Theory of Mechanics; and to the excellent practical treatise of the late Mr. Smeaton.

MILLEPES. See ONISCUS.

MILLEPORA. See MADREPORE, ZOOPHITES.

MILLERA, a genus of the syngenesia polygamia necessaria class of plants, the compound flower of which is radiated; there is scarcely any visible receptacle of the seeds, which are single after each particular flower, and have no pappus or down. There are three species.

MILLET. See MILLIUM and PANICUM.

MILLET-GRASS. See LILIUM.

MILLING. See FULLING.

MILLION, in arithmetic, the number of ten hundred thousand, or a thousand times a thousand.

MILLREE, a Portuguese gold coin, equal to 5*s.* 7½*d.* of our money.

MIMOSA, the *sensitive plant*, a genus of the polygamia order, in the monœcia class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The hermaphrodite calyx is quinquedentate; the corolla quinquefid; there are five or more stamina, one pistil, and a legumen; the male calyx is quinquedentate; the corolla quinquefid, with five, ten, or more stamina.

The name mimosa signifies "mimic;" and is given to this genus on account of the sensibility of the leaves, which, by their motion, mimic or imitate the motion of animals. This genus comprises 85 different species, all natives of warm climates. The sensitive kinds are exceedingly curious plants in the very singular circumstances of their leaves receding rapidly from the touch, and running up close together; and in some sorts the footstalks and all are affected, so as instantly to fall downward as if fastened by hinges, which last are called humble sensitives. They have all winged leaves, each wing consisting of many small pinnæ. The following are the most remarkable:

1. The *sensitiva*, or common sensitive humble plant, rises with an under-shrubby prickly stem, branching six or eight feet high, armed with crooked spines. This is somewhat of the humble sensitive kind; the leaves, footstalks and all, receding from the touch, though not with such facility as in some of the other sorts.

2. The *pudica*, or bashful humble plant, rises with an under-shrubby, delineated, prickly stem, branching two or three feet round, armed with hairy spines. This is truly of the humble sensitive kind; for by the least touch the leaves instantly recede, contract close, and together with the footstalk, quickly decline downward, as if ashamed at the approach of the hand.

3. The *scandens*, cacoons, or mafootoo wyth, is frequent in all the upland valleys and woodlands on the north side of Jamaica. It climbs up the tallest trees, and spreads itself in every direction by means of its cirrhi, or claspers, so as to form a complete arbour, and to cover the space of an English acre from one root, five inches broad, jointed, and containing 10 or 15 seeds. These seeds are brown, shining, flattened, and very hard, and called cacoons.

4. The *catechu*, according to Mr. Ker, grows only to 12 feet in height, and to one foot in diameter; it is covered with a thick, rough, brown bark, and towards the top divides into many close branches: the leaves are bipinnated, or doubly winged, and are placed alternately upon the younger branches: the partial pinnæ are nearly two inches long, and are commonly from 15 to 30 pair, having full glands inserted between the pinnæ: each wing is usually furnished with about 40 pair of pinnulæ or linear lobes, beset with short hairs: the spines are short. From this tree, which grows plentifully on the mountainous parts of Indostan, where it flowers in June, is produced the officinal drug long known in Europe by the name of terra japonica.

5. The *nilotica*, or true Egyptian acacia, rises to a greater height than the preceding. The fruit is a long pod, resembling that of the lupin, and contains many flattish, brown seeds. It is a native of Arabia and Egypt, and flowers in July. Although the mimosa nilotica grows in great abundance over the vast extent of Africa, yet gum arabic is produced chiefly by those trees which are situated near the equatorial regions; and we are told that in Lower Egypt the solar heat is neversufficiently intense for this purpose. The gum exudes in a liquid state from the bark of the trunk and branches of the tree, in a similar manner to the gum which is often produced upon the cherry-trees, &c. in this country; and by exposure to the air it soon acquires solidity and hardness.

MIMULUS, *monkey flower*, a genus of the didynamia angiospermia class of plants, with double stigmata, and a ringent monopetalous flower; the fruit is a bilocular capsule, with several seeds in each cell. There are three species.

MINA, in Grecian antiquity, a money of account, equal to a hundred drachms.

MINE, a deep pit under ground, whence various kinds of minerals are dug out; but the term is more particularly applied to those which yield metals. Where stones only are procured, the appellation of quarries is universally bestowed upon the places from which they are dug out, however deep they may be. Mines in general, then, may be said to be veins or cavities within the earth, whose sides receding from, or approaching nearer to each other, make them of unequal breadths in different places, sometimes forming larger spaces, which are called holes; they are filled, with substances, which, whether metallic or of any other nature, are called the lodes; when the substances forming these lodes are reducible to metal, the lodes are by the miners said to be alive; otherwise they are called dead lodes. In Cornwall and Devon the lodes always hold their course from eastward to westward, though in other parts of England, they frequently run from north to south. The sides of the lode never bear in a perpendicular, but constantly

The lode is frequently intercepted by the crossing of a vein of earth, or stone, or some different metallic substance, in which case it generally happens that one part of the lode is moved a considerable distance to the one side. This transient lode is by the miners called flooking; and the part of the lode which is to be moved, is said to be heaved. According to Dr. Nichols's observations upon mines, they seem to be, or to have been, the channels through which the waters pass within the earth, and, like rivers, have their small branches opening into them, in all directions. Most mines have streams of water running through them; and when they are found dry, it seems to be owing to the waters having changed their course as being obliged to it, either because the lode has stopped up the ancient passages, or that some new and more easy ones are made. Many mines have been discovered by accident: a torrent first laid open a rich vein of the silver mine at Friberg in Germany; sometimes a violent wind, by blowing up trees, or overturning the parts of rocks, has discovered a mine; the same has happened by violent showers, earthquakes, thunder, the firing of woods, or even the stroke of a ploughshare.

The principal signs of a latent metallic vein, seem reducible to general heads, such as, 1. The discovery of certain mineral waters. 2. The discoloration of the trees or grass of a place. 3. The finding of pieces of ore on the surface of the ground. 4. The rise of warm exhalations. 5. The finding of metallic sands, and the like. All which are so many encouragements for making a stricter search near the places where any thing of this kind appears; whence rules of practice might be formed for reducing this art to a greater certainty. But when no evident mark of a mine appears, the skilful mineralist usually bores into the earth, in such places as from some analogy of knowledge, gained by experience, or by observing the situation, course, or nature of other mines, he judges may contain metal.

After the mine is found, the next thing to be considered is, whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its situation, as to wood, water, carriage, healthiness, and the like, and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting.

The form and situation of the spot ought to be particularly considered. A mine must either happen, 1. In a mountain. 2. In a hill. 3. In a valley, or, 4. In a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits, or avenues may be here readily cut out, both to drain the water and to form gangways for bringing out the ore, &c. In all the four cases we are to look out for the veins which the rains, or other accidental things may have laid bare; and if such a vein be found, it may often be proper to open the mine at that place, especially if the vein prove tolerably large and rich: otherwise the most commodious place for situation is to be chosen for the purpose, viz. neither on a flat nor on the tops of mountains, but on the sides. The best situation for a mine, is a mountainous, woody, wholesome spot; of a safe easy ascent, and bordering on a navigable river.

Mine, in military affairs, is also a subterraneous cavity made according to the rules of art, in which a certain quantity of powder is lodged, which by its explosion blows up the earth above it. It has been found by experiment that the figure produced by the explosion is a paraboloid; and that the centre of the powder, or charge, occupies the focus. The place where the powder is lodged is called the chamber of the mine, or fornean. The passage leading to the powder is called the gallery.

The line drawn from the centre of the chamber, perpendicular to the nearest surface of the ground, is called the line of least resistance. The pit or hole, made by springing the mine, is called the excavation. The fire is communicated to the mine by a pipe or hose, made of coarse cloth, whose diameter is about one inch and a half, called the saucisson (for the filling of which near half a pound of powder is allowed to every foot), extending from the chamber to the entrance of the gallery; to the end of which is fixed a match, that the miner who sets fire to it may have time to retire before it reaches the chamber. To prevent the powder from contracting any dampness, the saucisson is laid in a small trough, called an auger, made of boards, three inches and a half broad, joined together lengthwise, with straw in it, and round the saucisson, with a wooden cover nailed upon it.

Galleries and chambers of mines.—The galleries made within the fortification before the place is attacked, and from which several branches are carried to different places, are from three to four feet, or four and a half wide, and five feet or five and a half high. The earth is supported from falling in by arches and walls, or wooden frames or props. The chamber is generally of a cubical form, large enough to hold the wooden box, which contains the powder. The chamber is sunk something lower than the gallery, if the soil permits; but where water is to be apprehended, it must be made higher than the gallery.

Quantities of powder to charge mines.—Before any calculation can be made of the proper charge for a mine, the density and tenacity of the soil in which it is to be made must be ascertained, either by experiment or otherwise. The density is determined by weighing a cubic foot (or any certain quantity) of the soil; but the tenacity can only be determined by making a mine. The following table contains experiments in six different soils, which may be of some assistance to form a judgment of the nature of the soil, when an actual experiment cannot be had.

	Density.	Tenacity.
Nature of the soil.	Weight of 1 Cubic foot.	Quantity of powder to raise 1 cub. fathom
1. Loose earth or sand	95 pds.	8 pds.
2. Common light soil	124	10
3. Loam, or strong soil	127	12¼
4. Potters' clay, or stiff soil	135	13½
5. Clay mixed with stones	160	16
6. Masonry	05	21½

Loading and stopping of mines. The gallery and chamber being ready to be loaded, a strong box of wood is made of the size and figure of the chamber, being about one-third, or one-fourth bigger than is required for containing the necessary quantity of powder: against the sides and bottom of the box is put some straw; and this straw is covered over with empty sand-bags, to prevent the powder from contracting any dampness: a hole is made in the side next the gallery, near the bottom, for the saucisson to pass through; which is fixed to the middle of the bottom by means of a wooden peg, to prevent its loosening from the powder; or that, if the enemy should get to the entrance, he may not be able to tear it out. This done, the powder is brought in sand-bags, and thrown loose in the box, and covered also with straw and sand-bags; upon this is put the cover of the box, pressed down very tight with strong props; and, to render them more secure, planks are also put above them, against the earth, and wedged in as fast as possible. This done, the vacant spaces between the props are filled up with stones and dung, and rammed in the strongest manner: the least neglect in this work will considerably alter the effect of the mine. The auget is then laid from the chamber to the entrance of the gallery, with some straw at the bottom, and the saucisson laid in it, with straw over it: lastly, it must be shut with a wooden cover nailed upon it. The gallery is stopped up with stones, earth, and dung, well rammed, six or seven feet further from the chamber than the length of the line of least resistance.

MINERAL WATERS. See WATERS.

MINERALOGY, is that science which treats of the solid and inanimate materials of which our globe consists; and these are usually arranged under four classes: the earthy, the saline, the inflammable, and the metallic, which are thus distinguished:

1. The earthy minerals compose the greater part of the crust of the earth, and generally form a covering to the rest. They are not remarkable for being heavy, brittle, or light-coloured. They are little disposed to chrystallize, are uninflammable in a low temperature, insipid, and without much smell.

2. The saline minerals are commonly moderately heavy, soft, sapid, and possess some degree of transparency.

3. The inflammable class of minerals is light, brittle, mostly opaque, of a yellow brown, or black colour, seldom chrystallize, and never feel cold.

4. Metallic minerals are characterized by being heavy, generally opaque, tough, malleable, cold, not easily inflamed, and by exhibiting a great variety of colours, of a peculiar lustre.

Under each of these classes are various genera, species, sub-species, and kinds, which will be noticed in order. Sometimes, as in the vegetable kingdom, we find a strict affinity between different species of minerals, and in that case they are said to belong to the same family; but in mineralogy, one class does not always blend with another in a chemical point of view, or furnish that beautiful gradation and almost imperceptible union which is to be traced in the other kingdoms of nature. As the external characters are of the first importance in facilitating our acquaintance with minerals, we shall briefly explain this subject, before we proceed to the classification of the different substances.

Of the external Characters of Minerals.

The external characters of minerals are either generic or specific. The generic characters are certain properties of minerals, without any reference to their differences, as colour, lustre, weight, &c.; and the differences between these properties form the specific characters.

Generic characters may be general or particular. In the first division are comprehended those that occur in all minerals, in the last those that are found only in particular classes of minerals.

The particular generic external characters are thus advantageously arranged:

1. Colour.

2. Cohesion of particles; distinguished into solid, friable, and fluid.

In solid minerals are to be regarded the external shape, the external surface, and the external lustre. When broken, the lustre of the fracture, the fracture itself, and the shape of the fragments, are to be noticed. In distinct concretions, regard must be paid to the shape of the concretions, their surface, their lustre, transparency, streak, and soiling. All these may be ascertained by the eye. By the touch, we may discover the hardness of minerals, their tenacity, frangibility, flexibility, their unctuosity, coldness, weight, and their adhesion to the tongue. By the ear we distinguish their sound, and by the smell and taste the qualities which these two senses indicate.

In friable minerals, external shape, lustre, aspect of particles, soiling, and degree of friability, are to be attended to.

In fluid minerals the lustre, transparency, and fluidity, are principal objects to be regarded.

The specific external characters of minerals are founded on the distinctions and varieties of the two great generic divisions. And first, of colours, the names of which are derived from certain bodies in which they most generally occur, either in a natural or artificial state, or from different mixtures and compositions of both.

I. Colour.

1. White. This may be snow-white, reddish-white, yellowish-white, silver-white, greyish-white, greenish-white, milk-white, or tin-white.

2. Grey. Lead-grey, blueish-grey, pearl-grey, reddish-grey, smoke-grey, greenish-grey, yellowish-grey, steel-grey, and ash-grey.

3. Black. Greyish-black, brownish-black, dark-black, iron-black, greenish-black, and blueish-black.

4. Blue. Indigo-blue, Prussian-blue, lavender-blue, smalt-blue, sky-blue.

5. Green. Verdigis-green, celaden green, mountain-green, emerald-green, leek-green, apple-green, grass-green, pistachio-green, asparagus-green, olive-green, blackish-green, canary-green.

6. Yellow. Sulphur-yellow, lemon-yellow, gold-yellow, bell-metal-yellow, straw-yellow, wine-yellow, Isabella-yellow, ochre-yellow orange-yellow, honey-yellow, wax-yellow, and brass-yellow.

7. **Red.** Morning-red, hyacinth-red, brick-red, scarlet-red, copper-red, blood-red, carmine-red, cochineal-red, crimson-red, columbine-red, flesh-red, rose-red, peach-blossom-red, cherry-red, brownish-red.

8. **Brown.** Reddish-brown, clove-brown, hair-brown, yellowish-brown, tombac-brown, wood-brown, liver-brown, blackish-brown.

Besides these distinctions, colours may be clear, dark, light, or pale; they may have a tarnished appearance, a play, a changeability, an iridescence, an opalescence, a permanent alteration, and a delineation of figure or pattern, such as dotted, spotted, clouded, flamed, striped, veined, dendritic, or ruiniform.

II. COHESION OF PARTICLES.

Minerals are divided into, 1. Solid, or such as have their parts coherent, and not easily moveable; 2. Friable, or that state of aggregation in which the particles may be overcome by simple pressure of the finger; and, 3. Fluid, or such as consist of particles which alter their place in regard to each other by their own weight.

1. *Solid Minerals.*

External aspect has three things to be regarded, 1. The shape; 2. The surface; and 3. The lustre. The external shape again may be common, particular, regular, or extraneous; and hence arise the specific differences.

1. The common external shape may be massive; disseminated coarsely, minutely, or finely; in angular pieces, sharp cornered or blunt cornered; in grains, large, coarse, small, fine, angular, flat, round; in plates, thick or thin; in membranes or flakes, thick, thin, or very thin.

The particular external shape may be longish, as dentiform, filliform, capillary, reticulatic, dendritic, coralliform, stalactitic, cylindrical, tubiform, claviform, or fruticose; roundish, as globular, spherical, ovoidal, spheroidal, amygdaloidal, botryoidal, reniform, tuberose, or fused-like; flat, as specular, or in leaves; cavernous, as cellular in various forms, with impressions, perforated, corroded, amorphous, or vesicular; entangled, as ramose, &c.

In the regular external shape or chrystallization are to be regarded its genuineness, according to which it may be either true or suppositious; its shape, made up of planes, edges angles, in which are to be observed the fundamental figure and its parts, the kind of fundamental figure, the varieties of each kind of fundamental figure, with their accidents and distinctions, and the alterations which the fundamental figure undergoes by truncation, by bevelment, by acumination, or by a division of the planes. There are a variety of figures under each of these subdivisions. It must be remarked also, that the external shape may be extraneous, or derived from the animal and vegetable kingdoms, as in fossils and petrifications.

2. The external surface contains several varieties of distinctions. It may be uneven, granulated, rough, smooth, or streaked in various ways and directions.

3. The external lustre is the third generic external character, and is of much importance to be attended to. In this we have to consider the intensity of the lustre, whether it is splendent, shining, glistening, glimmering, or dull; next the sort of lustre, whether metallic or common. The latter is distinguished into semimetallic, adamantine, pearly, resinous, and vitreous.

Aspect of the Fracture of solid Minerals.

After the external aspect, the fracture forms no inconsiderable character in minerals. Its lustre may be determined as in the external lustre; but the fracture itself admits of great varieties. It may be compact splintery, coarsely splintery, finely splintery, even, conchoidal, uneven, earthy, hackly. If the fracture is fibrous, we are to consider the thickness of the fibres, if coarse or delicate; the direction of the fibres, if straight or curved; and the position of the fibres, if parallel or diverging.

In the radiated fracture we are to regard the breadth of the rays, their direction, their position, their passage or cleavage. In the foliated fracture, the size of the folia, their degree of perfection, their direction, position, aspect of their surface, passage or cleavage, and the number of cleavages, are to be noted.

The shape of the fragments may also be very various-regular, as cubic, rhomboidal, trapezoidal, &c. or irregular, as cuneiform, splintery, tabular, indeterminately angular.

Aspect of the distinct Concretions.

The shape of the distinct concretions forms very prominent external characters. They may be granular, different in shape, or in magnitude; they may be lamellar, distinct, concretions, differing in the direction of the lamellæ, in the thickness, with regard to shape, and in the position.

The surface of the distinct concretions may be smooth, rough, streaked, or uneven; as for their lustre, it may be determined in the same manner as the external lustre.

General Aspect as to Transparency.

Minerals, as is well known, have different degrees of transparency, which may be considered among their external characters.—They may be transparent, semitransparent, translucent, translucent at the edges, or opaque.

The Streak.

The colour of this external character may be either similar or different. It is presented to us when a mineral is scraped with the point of a knife: and is similar, when the powder that is formed is of the same colour with the mineral, as in chalk; or dissimilar or different, as in cinnabar, orpiment, &c.

The Soiling or Colouring

Is ascertained by taking any mineral substance between the fingers, or drawing it across some other body. It may soil strongly, as in chalk, slightly, as in molybdena, or not at all, which is a quality belonging to most of the solid minerals. All the preceding external characters are recognized by the eye.

External Characters from the Touch.

These are eight in number, and are not destitute of utility to the mineralogical student. 1. Hardness; 2. Tenacity; 3. Frangibility; 4. Flexibility; 5. Adhesion to the tongue; 6. Unctuosity; 7. Coldness; 8 Weight.

Hardness may be tried by a capacity to resist the file, yielding a little to it, being semi-hard, soft, or very soft. Tenacity has different degrees, in substances being brittle, sectile or mild, or ductile. The frangibility consists in minerals being very difficultly frangible, difficultly frangible, easily frangible, or very easily frangible. The flexibility is proved by being simply flexible, elasticly flexible, commonly flexible, or inflexible. The adhesion to the tongue may be strongly adhesive, pretty strongly, weakly, very weakly, or not at all. Unctuosity may be meagre, rather greasy, greasy, or very greasy. Coldness is subdivided into cold, pretty cold, rather cold. Weight may be distinguished into swimming or supernatant, light, rather light, heavy, very heavy. The three last divisions from the touch, are in the Wernerian system regarded as anomalous; but they seem properly to be classed under this head.

External Characters from the Sound or Hearing.

The different kinds of sound which occur in the mineral kingdom are, 1. A ringing sound, as in native arsenic and thin splinters of hornstone; 2. A grating sound, as in fresh-burnt clay; 3. A creaking sound, as that of natural amalgam.

2. *Friable Minerals.*

The external characters drawn from minerals of this class are derived, first, from the external shape, which may be massive, disseminated, thinly, coating, spumous, or dendritic: secondly, from the lustre, regarded under its intensity, whether glimmering or dull, and its sort, whether common glimmering or metallic glimmering: thirdly, from the aspect of the particles, as being dusty or scaly: fourthly, from soiling or colouring, as strongly or lightly: and lastly, from the friability, which may be loose or cohering.

3. *Fluid Minerals.*

Of external characters drawn from fluid minerals, there are only two kinds, which include three varieties: 1. The lustre, which is either metallic, as in mercury, or resinous, as in rock oil. 2. The transparency, which is transparent, as in naphtha; turbid, as in mineral oil; or opaque, as in mercury. 3. The fluidity, which may be fluid, as in mercury, or viscid, as in mountain tar.

External Characters from the Smell.

These may be spontaneously emitted and described, as bituminous, faintly sulphureous, or faintly bitter; or they may be produced by breathing on, and yield a clay-like smell; or they may be excited by friction, and smell urinous, sulphureous, garlick-like, or empyreumatic.

External Character from the Taste.

This character prevails chiefly in the saline class, and it contains the following varieties: a sweetish taste, sweetish astringent, styptic, saltly bitter, saltly cooling, alkaline, or urinous.

Having now given a synoptical view of the external characters of minerals, we shall proceed to their classification, and in this we shall chiefly follow the names and arrangement of professor Jameson

CLASS I.

EARTHY FOSSILS.

First Genus. DIAMOND.

Diamond.

This precious stone has great variety of shades, exhibiting a beautiful play of colours. It occurs in indeterminately angular and completely spherical grains, which present planes of chrystallization, or are actually chrystallized. Its fundamental chrystal is the octaedron, which passes into various forms. It is hard in the highest degree, brittle, not very difficultly frangible, and has a specific gravity of 3.600.

The diamond has, by modern experiments, been proved to be nearly pure carbon, and begins to burn at 14° or 15° of Wedgewood.

Second Genus. ZIRCON.

First Species. *Zircon.*

The prevailing colour is grey, but it occurs likewise green, blue, red, yellow, and brown, with various intermediate tints.

It is found most commonly in roundish angular pieces, with rounded angles and edges. When chrystallized, the figure is generally a rectangular four-sided prism.

Second Species. *Hyacinth.*

The chief colour is red, passing to reddish-brown, and to orange-yellow. The figure a rectangular four-sided prism, flatly acuminated by four planes, which are set in the lateral edges. Of this figure, however, several varieties occur.

The chrystals are generally small, and always imbedded. The lateral planes smooth, and externally shining. Internally it is splendent and glassy, inclining somewhat to resinous.

Third Genus. FLINT.

First Species. *Chrysoberyl.*

The prevailing or general colour is asparagus-green, passing into a variety of allied shades. It exhibits a milk-white light; occurs in roundish and angular grains, which sometimes approach in shape to the cube. It is seldom chrystallized; but when in this state, it commonly presents a longish six-sided table, having truncated lateral edges, and longitudinally streaked lateral planes. The chrystals are small, externally shining, and internally splendent. It is hard, brittle, not very easily frangible, with a specific gravity of 3.600. Without addition, it is infusible.

Second Species. *Chrysolite.*

The chief colour is pistachio-green, of all degrees of intensity. It occurs in original angular sharp-edged pieces, with a rough, scaly, splintery surface, and when chrystallized, exhibits a broad rectangular four-sided prism, with its lateral edges sometimes truncated, sometimes bevelled, and acuminated by six planes. The external surface of the chrystals is splendent, internally splendent, and vitreous.

Third Species. *Olivine.*

The colour is generally asparagus-green, of various degrees of intensity. It is found imbedded also in roundish pieces and grains; and when chrystallized, which is rare, in rectangular four-sided prisms. Internally, it is

shining, varying between glistening and splendent. It is semitransparent, very easily frangible; in a low degree hard, and not particularly heavy. It is nearly infusible without addition. Occurs imbedded in basalt.

Fourth species. Augite.

The general colour is blackish-green. It occurs chiefly in indeterminate angular pieces and roundish grains. Occasionally it is chrystallized, and presents broad rectangular six-sided prisms. The chrystals are mostly small. Internally the lustre is shining, approaching sometimes to splendent. The augite is only translucent, and but faintly transparent. It is hard, not very easily frangible, and not particularly heavy. It is found in basalt, either singly or accompanied with olivine.

Fifth species. Vesuviane.

Its principal colour is dark olive-green, passing into other allied shades. It occurs massive, and often chrystallized in rectangular four-sided prisms. The chrystals are mostly short, and placed on one another. The vesuviane is translucent, hard in a moderate degree, and approaching to heavy. Before the blowpipe it melts without addition. It is found among the exuviæ of Vesuvius, from whence it derives its name in Siberia and Kamtschatka.

Sixth species. Leuzite.

The colours are yellowish and greyish-white. It occurs mostly in original round and angular grains. When chrystallized, it exhibits acute double eight-sided pyramids. Internally it is shining, and approaching to glistening, with a vitreous lustre, inclining somewhat to resinous. The leuzite is translucent and semitransparent. It is hard in a low degree, brittle, easily frangible, and not very heavy.

Seventh species. Melanite.

The general colour is velvet-black. It occurs chrystallized in a six-sided prism. The chrystals are middle sized or small. Externally they are smooth and shining, approaching to splendent; internally shining, inclining to glistening. The melanite is opaque, hard, pretty easily frangible, and not very heavy. It occurs imbedded in rocks of the newest floetz trap formation.

Eighth species. Garnet.

This is divided into two sub-species, the precious garnet and the common garnet.

Ninth species. Pyrope.

The colour is dark-blood red. It occurs in small and middle-sized roundish and angular grains: but never chrystallized. Its lustre is splendent and vitreous. It is completely transparent, hard so as to scratch quartz, and not particularly heavy. It is found imbedded in serpentine in Saxony and Bohemia. In Scotland, it is found in the sand on the sea-shore. It is employed in various kinds of jewellery, and is generally set in a good foil.

Tenth species. Grenatite.

The colour is a dark reddish-brown. It is always chrystallized in broad six-sided prisms. The chrystals are small and middle sized, internally glistening, with a lustre between vitreous and resinous. The grenatite varies from opaque to translucent, is hard, brittle, easily frangible, and not particularly heavy. It is found imbedded in mica slate..

Eleventh species. Spinelle.

The predominant colour is red, which passes on into blue, green, yellow, and brown. It occurs in grains, and likewise chrystallized in octaedrons with several variations. The chrystals are very rarely middle sized. Externally and internally the lustre is splendent and vitreous. It is fusible with borax: occurs in rocks belonging to the newest floetz trap formation. It is used as a precious stone, and considerably valued.

Twelfth species. Sapphire.

The principal colour Berlin blue; but it is found also red, with all the intermediate shades between these two colours. It occurs in small rolled pieces, and chrystallized in double three-side pyramids. The chrystals are small and middle sized. Internally the lustre is splendent and vitreous. Some varieties, when cut, exhibit a star of six rays. The sapphire is hard in the highest degree, but yields to the diamond; it is easily frangible, and rather heavy, having a specific gravity of about 4,000. It is infusible without addition: occurs in rocks of the newest floetz trap formation. This precious stone is found in the utmost beauty in Pegu and Ceylon.

Thirteenth species. Corundum.

See Corundum.

Fourteenth species. Diamond Spar.

The colour is a dark hair brown. It occurs massive, disseminated, in rolled pieces, and chrystallized in six-sided prisms, or very acute six-sided pyramids. Internally, its lustre is splendent, approaching in a slight degree to adamantine. It is translucent on the edges, hard in a high degree, easily frangible, and not particularly heavy. It has hitherto been found only in China. Both this stone and corundum are employed in cutting and polishing hard minerals, and they seem to be nearly allied to each other.

Fifteenth species. Emery.

See Emery.

Sixteenth species. Topaz.

The chief colour is a wine-yellow, of all degrees of intensity. It is found massive, disseminated, and sometimes rolled, but most commonly chrystallized in oblique eight-sided or four-sided prisms, which exhibit several varieties. The chrystals are small and middle-sized, externally splendent; internally splendent, and shining: lustre vitreous. The topaz alternates from translucent to transparent, and is duplicating transparent. It is hard in a high degree, easily frangible, and is not particularly heavy. It is fusible with borax; and some kinds in a gentle heat turn white, and are sometimes sold for diamonds. It is commonly found in veins that traverse primitive rocks.

Seventeenth species. Emerald.

Which see

Eighteenth species. Beryl.

This is divided into two sub-species, the precious and the schorlous beryl. See BERYL.

Nineteenth species. Schorl.

This is divided into sub-species, common schorl and tourmaline.

Twentieth species. Thumerstone.

The colour is commonly clove-brown, of various degrees of intensity. It is occasionally found massive, more frequently disseminated; but generally chrystallized in very flat and oblique rhombs. Externally, its lustre is generally splendent; internally, it alternates from glistening to shining, and is vitreous.

This species alternates from perfectly transparent to weakly translucent. It is pretty hard, very easily frangible, and not particularly heavy. It appears to be peculiar to the primitive mountains.

Twenty-first Species. * *Iron-Flint.*

The colour is a yellowish-brown, bordering on liver-brown. It occurs commonly massive, but also chrystallized in small equiangular six-sided prisms. Externally, its lustre is splendent; internally, shining, and is intermediate between vitreous and resinous.

Iron-flint is opaque, and slightly translucent on the edges. It is pretty hard, somewhat difficultly frangible, and approaching to heavy. It occurs in iron stone veins, and is found in Saxony, and, according to Larsten, at Bristol. It renders the iron ore, along with which it is dug, very difficult of fusion.

Twenty-second species. Quartz.

Werner divides this into five sub-species amethyst, rock chrystal, milk-quartz, common quartz, and prase. See QUARTZ, AMETHYST, &c.

Twenty-third species. Horn Stone.

Horn stone is divided into three sub-species, splintery horn-stone, conchoidal horn-stone, and wood-stone. See HORN-STONE.

Twenty-fourth species. Flint.

The general colour is grey, but with many varieties. It occurs massive, in regular plates in angular grains and species, in globular and elliptical rolled pieces, in the form of sand, and tuberose and perforated. Sometimes it is chrystallized, when it exhibits double six-sided prisms, or flat double three-sided pyramids. Internally, the lustre is glimmering translucent on the edges, hard, easily frangible, and not particularly heavy.

Twenty-fifth species. Chalcedony.

This is divided into two sub-species, chalcedony and carnelian, which see.

Agate.

The fossils known under this name are all compound substances; and hence cannot have a particular place in any systematic arrangement. Werner therefore has placed them as a supplement to the species chalcedony, which forms a principal constituent part of them. See AGATE.

Twenty-sixth species. Heliotrope.

Which see.

Twenty-seventh species. Plasma.

The usual colour is intermediate between grass and leek-green, and of different degrees of intensity. It occurs in indeterminably angular pieces, which have a rough earthy crust. Internally its lustre is glistening. It is intermediate between semitransparent and strongly translucent, hard, brittle, frangible without great difficulty, and not particularly heavy.

Twenty-eighth species. Chrysoprase.

Which see.

Twenty-ninth species. Flinty Slate.

This has been divided into two sub-species, common flinty slate, and Lydian stone.

Thirtieth species. Cat's Eye.

The principal colour is grey, of which it presents many varieties. It occurs in blunt-edged pieces, in rolled pieces, and likewise massive. Internally, it is shining; usually translucent, and sometimes also semitransparent. It is hard, easily frangible, and not particularly heavy.

Its geognostic situation is unknown. It is imported from Ceylon and the coast of Malabar; and is usually cut for ring-stones. Some of the varieties are highly valued.

Thirty-first species. Prehnite.

The colours are various shades of green, white, and yellow. It is sometimes massive and sometimes chrystallized in oblique four-sided tables. Externally, the chrystals are smooth and shining; internally, inclining to glistening and pearly.

Prehnite is translucent, sometimes passing into semi-transparent and transparent: it is hard, easily frangible, and not very heavy.

Thirty-second species. Zeolite.

This species is divided by Werner into five sub-species, 1. Mealy zeolite; 2. Fibrous zeolite; 3. Radiated zeolite; 4. Foliated zeolite; 5. Cubic zeolite.

All the different sub-species are natives of Scotland.

Thirty-third species. Cross Stone.

The colour is a greyish-white. It occurs chrystallized, either in broad rectangular four-sided prisms, or in twin chrystals. The chrystals are mostly small, and aggregated on one another. Both the internal and the external lustre is shining, inclining to splendent or glistening.

The cross-stone is translucent passing to transparent semi-hard, easily frangible, and not particularly heavy. It has hitherto been found only in mineral veins, and in agate-balls.

Thirty-fourth species. Agate Stone.

The colour is a perfect azure blue, of different shades. It is found massive, disseminated, and in rolled pieces. The lustre is glistening and glimmering. It is translucent on the edges, pretty hard, brittle, easily frangible, and not particularly heavy. See AGATE.

FOURTH GENUS.

CLAY *Genus.*

Species 1.—Jasper
Species 2.—Opal.
Species 3.—Pitch Stone.
Species 4.—Obsidian.
Species 5.—Pearl Stone.
Species 6.—Pumice Stone.

Seventh species. Felspar.

Is divided into four sub-species; compact felspar, common felspar, adularia, and Labradore stone. Fig. 15.

Eighth species. Pure Clay.

Is snow white, with occasionally a yellowish tinge, and occurs in kidney-shaped pieces, which have no lustre.

Ninth species. Porcelain Earth.

The colour is generally a reddish-white, of various degrees of intensity. It occurs massive and disseminated; its particles are fine and dusty, slightly cohering, and feeling fine and light.

Tenth species. Common Clay.

This is divided into six sub-species, as follows.

1. Loam. 2. Potters' clay is of two kinds, earthy and slaty. 3. Pipeclay. 4. Variegated clay, commonly white red and yellow; striped, veined, and spotted. It occurs massive, is passing into friable, feels a little greasy, and adheres somewhat to the tongue. 5. Clay stone, commonly grey or red, with various intermediate tints. 6. Slate clay.

Species 11.—Polier, or polishing Stone.
Species 12.—Tripoli.
Species 13.—Alum Stone.
Species 14.—Alum Earth.
Species 15.—Alum Slate.
Species 16.—Bituminous Shale.

Seventeenth species. Drawing Slate, or Black Chalk.

Its colour is a greyish-black, with a tinge of blue; it occurs massive, is opaque, colours and writes, is soft, mild, easily frangible, feels meagre but fine, and is rather light.

It is found in primitive mountains in France, Germany, Iceland, Scotland, and the Hebrides. When of a middling degree of hardness, it is used for drawing.

Eighteenth species. Whet Slate.

The common colour is greenish-grey, it is massive; internally, weakly glimmering, semi-hard, feels rather greasy, and it is not particularly brittle or heavy.

Nineteenth species. Clay Slate.

Its principal colour is grey, of which there are many varieties. It occurs massive; internally, its colour is glistening, the substance opaque, soft, and easily frangible. When spilt into thin and firm tables, it is used for roofing houses, and other purposes.

Twentieth species. Lepidolite.

Its colour is a kind of peach-blossom, red, verging on lilac-blue, and occurs massive. Its internal lustre is glistening; it is translucent, soft, easily frangible, and easily melts before the blowpipe. Hitherto it has only been found in Moravia, where it lies in gneiss. See MICA

Twenty-first species. Mica, or Glimmer.

Its common colour is grey, of great variety of shades.

Twenty-second species. Pot Stone.

Its colour is a greenish-grey, of different degrees of intensity; is massive; lustre, internally, glistening and pearly, translucent on the edges; soft, feels greasy, and is very difficultly frangible.

Twenty-third species. Chlorite,

Which see.

Twenty-fourth species. Horenblende,

Which see.

Twenty-fifth species. Basalt.

See BASALT.

Twenty-sixth species. Wacke.

The colour is a greenish-grey, of various degrees of intensity. It occurs massive and vesicular, is dull, somewhat glimmering, opaque, usually soft, more or less easily frangible, and not particularly heavy.

Twenty-seventh species. Clink Stone

Is commonly of a dark greenish-grey colour, always massive, and occurring in irregular columns, and tabular distinct concretions. It is usually translucent on the edges, brittle, easily frangible, and when struck with a hammer, sounds like a piece of metal.

It is said to belong to the floetz trap formation, and generally rests on basalt.

Twenty-eighth species. Lava.

Is divided into two sub-species.

1. Slag lava is a of greyish-black colour, passing into other shades.

2. Foam lava is of a dark greenish-grey colour, occurs small and fine, vesicular; externally, glimmering, slightly translucent on the edges, brittle, easily frangible, and light.

Twenty-ninth species. Green Earth.

Its colour is a celaden green, of various degrees of intensity. It occurs massive, in angular and globular pieces, and also disseminated. Internally, it is dull, streak glistening, very soft, easily frangible, and light.

It is principally found in amygdaloid, in Saxony, Bohemia, Scotland, and other places, and is used by painters.

Thirtieth species. Lithomage.

Is divided into two sub-species.

1. Friable lithomage, or rockmarrow, is snow-white, or yellowish-white, occurs massive, as a crust, and disseminated.

2. Indurated lithomage is most commonly white, of which it presents several varieties; is massive; internally, dull; streak shining.

Thirty-first species. Rock Soap.

Is of a brownish or pitch-black colour, massive and disseminated, dull, oqaque, does not soil, writes like drawing-slate, is easily frangible, and adheres strongly to the tongue.

Thirty-second species. Yellow Earth.

The colour is ochre-yellow, of different degrees of intensity.

To the clay genus, likewise, belong adhesive slate, float-stone, pinite, and umber.

FIFTH GENUS.
TALC *Genus.*

Species 1.—Bole.
Species 2.—Native Talc Earth.
Species 3.—Meerschaum.
Species 4.—Fuller's Earth.
Species 5.—Neaphrite.
Species 6.—Steatite.
Species 7.—Serpentine, which see.
Species 8.—Schiller-Stone.
Species 9.—Talc.
Species 10.—Asbest. See *Asbestos.*
Species 11.—Cyanite, which see.

Twelfth species. Actynolite.

Is divided into the following sub-species:

1. Asbestous actynolite is of a greenish-grey colour, occurs massive, disseminated, and in capillary chrystals; is internally glistening, translucent on the edges, soft, brittle, not easily frangible, nor particularly heavy. It is found in mineral beds in Saxony, and other parts of Germany.

2. Common actynolite is generally of a green leek-colour, passing into other shades of the same; it occurs massive, and likewise chrystallized in very oblique six-sided prisms, is splendent externally semi-hard, rather brittle, and not easily frangible.

It is found in beds in primitive mountains, in Saxony, Switzerland, Norway, and Scotland.

3. Glassy actynolite is principally of mountain-green colour, of various degrees of intensity.

SIXTH GENUS
CALC *Genus.*

First species. Rock Milk.

Its colour is yellowish-white; it is composed of dully, dusty particles, generally weakly cohering, feels meagre, soils very much, and is very light.

Second species. Chalk.

Its colour is principally all yellowish-white: it occurs massive, disseminated, and as crust over flint.

Third species. Lime-Stone.

Is divided into several sub-species:

1. Compact lime-stone is of two varieties, common compact lime-stone, and roe-stone. The former is generally of a grey colour, but is frequently veined, zoned, striped, or clouded.

2. Foliated limestone is likewise of two kinds, granular limestone, and calc spar.

3. Fibrous limestone, is of two varieties, common fibrous limestone, and fibrous limestone, or calc sinter.

4. Pea-stone is commonly yellowish-white, massive, internally dull, opaque or translucent on the edges; soft, very easily frangible

Species 4.—Schaum, or foaming earth.
Species 5.—Slate spar.
Species 6.—Brown spar.
Species 7.—Rhomb spar See *Spar.*
Species 8.—Schaalstone
Species 9.—Stink-stone.
Species 10.—Marle.

Eleventh species. Bituminous marle slate.

Its colour is intermediate between greyish and brownish-black; it is massive, from glimmering to shining, fragments slaty, usually soft, not very brittle, easily frangible, and streak shining. It is found in beds along with the oldest floetz limestone, and contains much copper intermixed with it, on account of which it is usually smelted in Thuringia.

Twelfth species. Calc tuff.

The colour is yellowish-grey; it is generally perforated or marked with the impressions of other substances, also amorphous, ramose, and corroded.

Thirteenth species. Arragonite.

The principal colours are greenish-grey, and iron-grey. It occurs chrystallized in perfect equiangular six-sided prisms; the lustre is glistening, passing into shining, and is vitreous; it is semihard, brittle, not particularly heavy, and phurphuresces a little. It was first discovered in the province of Arragon, whence its name, imbedded in gyps.

Fourteenth species. Appatite.

The usual colours are white, green, blue and red; it generally occurs chrystallized, the radical form of which is the equiangular six-sided prism. Externally it is splendent, internally shining and resinous. It is commonly transparent semihard, brittle, easily frangible, and occurs in tin veins, &c. in Saxony, Bohemia, and in Cornwall. It has been confounded with schorl, &c. See fig. 20.

Fifteenth species. Asparagus or spargel stone.

Sixteenth species. Boracite.

Its colours are yellowish, smoke, and greyish white, passing to asparagus green; it occurs in chrystallized cubes, with the edges and angles truncated, internally shining, commonly semitransparent, semihard, brittle, and easily frangible. Hitherto it has been discovered only at Luneburg in Hanover.

Seventeenth species. Fluor

Which see.

Eighteenth species. Gyps.

This is divided into the following sub-species:

1. Gyps earth is of a yellowish-white colour, passing into some allied shades, is intermediate between fine scaly and dusky, dull and feebly glimmering, soils a little, feels meagre but soft and fine, and is light. It is found, though rarely, in gyps countries.

2. Compact gyps, is commonly ash grey, passing into smoke and yellowish-grey, is massive, internally dull, feebly translucent on the edges, very soft, frangible without great difficulty, and is employed in architecture and sculpture, under the name of alabaster.

3. Foliated gyps is commonly white, grey, or red, presenting spotted, striped, and veined colour delineations.

4. Fibrous gyps is principally white, grey, and red, with various shades of each.

Gyps, when burnt, forms an excellent cement, and is used for many ornamental purposes.

Nineteenth species. Selenite

Its principal colour is snow-white, passing into other neighbouring shades.

Twentieth species. Cube Spar.

The colour is milk-white with various allied shades.

SEVENTH GENUS.

BARYTE *genus.*

First species. Witherite.

Is commonly of a light yellowish-grey colour, generally massive, but sometimes chrystallized in six sided prims, or double six-sided pyramids.

Second species. Heavy spar or baryte.

See BARYTES.

EIGHTH GENUS.

STRONTIAN *genus.*

First species. Strontian.

The usual colour is intermediate between asparagus and apple-green; it occurs most commonly massive, but sometimes chrystallized in a circular six-sided prism. The lustre of the principal fracture is shining, of the cross fracture glistening. It occurs along with lead-glance, heavy spar, &c. at Strontian in Argyleshire.

Second species. Celestine

Is divided into two sub-species:

1. Fibrous celestine, is of an intermediate colour, between indigo-blue and blueish-grey; it occurs massive and in plates, and also chrystallized, shewing a tendency to prismatic distinct concretions; is translucent, soft or semihard, easily frangible, and pretty heavy.

2. Foliated celestine, is of a milky-white colour, falling into blue; it occurs massive, and also chrystallized in six sided tables intersecting each other. It has a glistening lustre, is strongly translucent, softish, not particularly brittle, easily frangible, and hard. It occurs sometimes in sulphur beds, and is found very finely chrystallized in Sicily, and likewise near Bristol.

CLASS II.

FOSSIL SALTS.

The substances included in this class are confined to those which are found in a natural state only; and the greater part of them appear to be formed by the agency of water, air, &c. The distinguishing characters of fossil salts are, their taste and easy solution. They resemble each other so closely, that the term *saline consistence* is used to express whatever relates to hardness, tenacity, and frangibility.

Species 1.—Natron, or natural soda.
Species 2.—Natural nitre,
Species 3.—Natural rock-salt.
Species 4.—Natural sal-ammoniac.
Species 5.—Natural Epsom salt.
Species 6.—Natural Glauber salt.
Species 7.—Natural alum.
Species 8.—Hair salt.

Ninth species. Rock Butter.

The colour is light-yellow or greyish-white. It occurs massive and tuberose, is translucent, has a saline consistence, or sweetish-sour astringent taste, and feels a little greasy. It oozes out of fissures of rocks of alum slate, and is found in Lusatia, Thuringia, Denmark, Siberia, and near Paisley in Scotland.

Tenth species. Natural Vitriol

Is divided into the three following sub-species, viz. iron, copper, and zinc vitriol.

Here it must be remarked, that borax, though so well known by name, is without a place in the Wernerian system, as it is uncertain whether or not it occurs in a solid state. It is most probable that it occurs only in solution in certain lakes. See BORAX.

The new genus stallite, of which only one species, cryolite, has been found in Greenland, seems properly to come under this head.

CLASS III.

INFLAMMABLE FOSSILS.

Fossils belonging to this class are light, brittle, mostly opaque, yellow, brown, or black, seldom chrystallized, and never feels cold. They are more nearly allied to the metallic than to the earthy or saline classes.

FIRST GENUS.

SULPHUR *genus.*

First species. Natural sulphur.

It contains the two following sub-species:

1. Common natural sulphur, is of the colour the name expresses, but of different degrees of intensity.

2. Volcanic natural sulphur is of the colour the name imports, but with a considerable tinge of green.

SECOND GENUS.

BITUMINOUS *genus.* See BITUMENS.

First Species. Brown Coal. See COAL.

THIRD GENUS.

GRAPHITE *genus.*

First species. Glance Coal.

This is divided into two sub-species:

1. Conchoidal glance coal is of an iron-black colour, of different degrees of intensity, occurs massive and vesicular, internally shining, bordering sometimes on semihard, brittle, easily frangible, and light.

2. Slaty glance coal is of a dark iron-black colour, occurs massive, is shining and glistening, soft, very easily frangible, light, and intermediate between sectile and brittle.

Second species. Graphite.

This contains two sub-species:

1. Scaly graphite is commonly of a dark steel-grey colour.

2. Compact graphite is rather blacker than the preceding, is internally glimmering with a metallic lustre.

Third species. Mineral charcoal.

The colour is a greyish-black. It occurs in small angular and somewhat cubical-shaped pieces, is glimmering, with a silky lustre, soils strongly, is soft, and light. It is found in thin layers in different kinds of coal, and is widely disseminated.

FIFTH GENUS.

RESIN *genus.* See RESINS.

First species. Amber.

This is divided into the two following sub-species:

1. White amber is of a straw-yellowish colour. It occurs massive, and sometimes associated with the following sub-species.

2. Yellow amber is of a wax-yellow colour, passing into several neighbouring shades. It admits of a fine polish, and is cut into necklaces, bracelets, snuff-boxes, and various other articles.

Second species. Honeystone.

See MELLITE.

CLASS IV.

METALLIC FOSSILS.

FIRST, PLATINA *Genus.*

First species. Native platina.

The colour is very light steel-grey, approaching to silver-white. See PLATINA.

SECOND GENUS. *Gold.*

First species. Native gold.

This is divided into two sub-species:

1. Gold yellow native gold is of a perfect colour, corresponding to its name.

2. Brass-yellow native gold is principally of the colour of brass, occurs disseminated, capillary, moss-like, reticulated, and in leaves, also chrystallized in thin six-sided cubes, and is rather lighter than the preceding.

3. Greyish-yellow native gold is of a brass-yellow colour falling into steel-grey, occurs in very small flattish grains like platina.

THIRD GENUS. *Mercury,* which see.

Species 1.—Native mercury, or quicksilver.
Species 2.—Natural amalgam.
Species 3.—Mercurial horn-ore, or corneous mercury.
Species 4.—Mercurial liver-ore, or mercurial hepaticore.
Species 5.—Cinnabar.

FOURTH GENUS. *Silver.*

First species. Native silver.

Common native silver is of the colour the name expresses. It occurs massive, disseminated, in pieces, plates, and membranes, as well as in other forms. It is soft, perfectly malleable, common flexible, and very heavy when pure. See CHEMISTRY.

Species 2.—Antimonial silver.
Species 3.—Arsenical silver.
Species 4.—Corneous silver-ore, or horn-ore.
Species 5.—Silver-black.
Species 6.—Silver-glance.
Species 7.—Brittle silver-glance.
Species 8.—Red silver-ore.
Species 9.—White silver-ore.
Species 10.—Black silver-ore.

FIFTH GENUS. *Copper,* which see.

First species. Native copper.

The colour is copper-red, but frequently tarnished.

Second species. Copper glance.

Compact copper-glance is usually of a dark lead-colour, passing into blackish-grey.

Third species. Variegated copper-ore.

Its colour, when dug, is intermediate between copper-red and pinchbeck-brown, but it soon becomes tarnished. It occurs massive, disseminated in plates, membranes, and chrystallized in octahedrons.

Species 4.—Copper pyrites.
Species 5.—White copper-ore.

Sixth species. Grey copper-ore, or Fahl ore.

The most common colour is steel grey: it occurs massive, disseminated, and also chrystallized in tetrahedrons, octahedrons, and garnet dodecahedrons.

Species 7.—Copper black.
Species 8.—Red copper ore.
Species 9.—Tile oar.
Species 10.—Copper azure.
Species 11.—Malachite.

Eleventh species. Malachite, which see.

Twelfth species. Copper-green.

The principal colour is verdigris-green, of different degrees of intensity.

Thirteenth species. Iron-shot copper-green.

Earthy iron-shot copper-green is usually of an olive-green colour: occurs massive, and disseminated.

Fourteenth species. Copper-emerald.

The colour is an emerald-green. It occurs in chrystallized six-sided prisms, which are externally and internally shining.

Fifteenth species. Copper-mica.

Is usually of an emerald-green colour: it occurs massive, disseminated, and occasionally chrystallized in very thin six-sided tables. It is soft, sectile, not very brittle, nor particularly heavy; and has hitherto been found only in veins in Cornwall, where it passes under the unscientific name of foliatic arseniate of copper.

Sixteenth species. Lenticular ore.

The colour is sky-blue, sometimes passing into verdigris green.

Seventeenth species. Oliven ore.

Foliated oliven ore is of a perfect olive-green: seldom occurs massive, usually in drusy crusts, and in small chrystals.

SIXTH GENUS. *Iron.*

First species. Native iron

Is of a light steel-grey colour, inclining to silver-white: it has hitherto been found only ramose; internally it is intermediate between glimmering and glistening, with a perfect metallic lustre, and a hackly fracture. It is between soft and semihard, perfectly malleable, common flexible, difficultly frangible, and uncommonly heavy. Hitherto it has been found

only in loose masses on the surface of the earth, and is a rare production.

Second species. Iron pyrites.

Common iron pyrites is usually of a perfect bronze-yellow colour: it occurs massive, disseminated, in membranes, and also chrystallized in cubes, octahedrons, dodecahedrons, icosahedrons, and leuzite chrystals.

Third species. Magnetic pyrites

Is of an intermediate colour between bronze-yellow and copper-red: it occurs massive and disseminated.

Fourth species. Magnetic iron stone.

Common magnetic iron-stone is of an iron-black colour: is massive, disseminated, and also chrystallized in cubes, octahedrons, and garnet dodecahedrons, and rectangular four-sided prisms. It is externally shining; internally between splendent and glistening, with a metallic lustre; is intermediate between hard and semihard, brittle, and heavy. It occurs most frequently in primitive mountains. When pure, it affords excellent bar iron.

Fifth species. Iron glance.

Common iron glance is usually of a dark steel grey colour, with several different shades. It commonly occurs massive and disseminated, and also chrystallized in flat, double, three-sided pyramids, and in double three-sided pyramids.

Sixth species. Red iron-stone.

Red iron froth. The colour is intermediate between cherry-red and brownish-red. It occurs commonly friable, massive, sometimes coating and disseminated, and is composed of sealy particles, which are glimmering, and have a semi-metallic lustre.

Seventh species. Brown iron-stone.

Brown iron froth is of an intermediate colour between steel-grey and clove-brown, and is between friable and solid. It occurs massive, coating, spumous, &c. and is composed of scaly particles, shining and glistening, with a metallic lustre. It soils strongly, feels greasy, and is very light.

Eighth species. Sparry iron-stone.

The principal colour is a light yellowish grey, which, on exposure to the hair or heat, changes into brown or black. It occurs massive, disseminated, with pyramidal impressions, in plates, and chrystallized. It is chiefly confined to the primitive and floetz mountains.

Ninth species. Black iron-stone.

Compact black iron-stone, is of an intermediate colour between bluish-black, and dark steel grey.

Tenth species. Clay iron-stone.

Reddle is of a light brownish-red, passing into cherry-red: it occurs only massive; soils strongly, and writes, is sectile, easily frangible, and rather heavy. It is chiefly found in the newer clay-slate, and is produced pretty abundantly in Germany and Siberia. The coarser varieties are used by the carpenter, the finer by the painter, under the name of red chalk

Eleventh species. Bog iron-ore.

Morass ore is of a yellow-brown colour, sometimes friable, sometimes coherent, and occurs massive.

Twelfth species. Blue iron-earth.

When fresh it is whitish, but soon becomes of an indigo-blue colour, of different degrees of intensity.

Thirteenth species. Green iron-earth.

Friable green iron-earth is of a siskin-green colour, occurs massive and disseminated, is more or less cohering, soft, fine, easily frangible, and intermediate between particularly heavy and heavy.

Fourteenth species. Cube ore.

The colour is olive-green, of different degrees of intensity; it occurs massive, and chrystallized in small cubes.

SEVENTH GENUS. *Lead.*

First species. Lead glance.

Common lead glance is of a fresh lead-grey colour, of different degrees of intensity; it occurs massive, disseminated, in membranes, &c. and also chrystallized in cubes, octahedrons, four-sided prisms, six-sided prisms, and three-sided tables. It is soft, sectile, externally easily frangible, and uncommonly heavy; and is found in veins and beds in primitive, transitive, and floetz mountains. It is most frequently worked as an ore of lead, but sometimes as an ore of silver.

Species 2.—Blue-lead ore.
Species 3.—Brown-lead ore.
Species 4.—Black-lead ore.
Species 5.—White-lead ore.
Species 6.—Green-lead ore.
Species 7.—Red-lead ore.
Species 8.—Yellow-red ore.

Ninth species. Lead vitriol, or vitriol of lead.

The colour is yellowish-grey and greyish-white; it occurs only chrystallized in octahedrons of different figures.

Tenth species. Lead earth

Coherent lead earth is usually of a yellowish-grey colour; it occurs massive, is internally glimmering, and usually opaque.

EIGHTH GENUS. *Tin.*

First species. Tin pyrites.

The colour is intermediate between steel-grey and brass-yellow; it occurs massive and disseminated.

Second species. Tin stone.

The most common colour is blackish-brown.

Third species. Cornish tin ore, or wood tin.

The most usual colour is hair-brown, of different degrees of intensity; it occurs usually in rolled pieces.

NINTH GENUS. *Bismuth.*

First species. Native bismuth.

Its colour is silver-white, with an incli-

nation to red; it occurs massive disseminated in leaves, reticulated, and chrystallized in small four-sided tables.

Second species. Bismuth glance.

The colour is a light lead-grey; it occurs massive, disseminated, and in acicular and capillary chrystals.

Third species. Bismuth-ochre.

The colour is a straw-yellow, passing into other neighbouring shades.

TENTH GENUS. *Zinc.*

First species. Blende.

Yellow blende is of a dark wax and sulphur yellow colour; it usually occurs massive and disseminated.

Second species. Calamine.

The general colour is yellowish-grey, which passes into other neighbouring shades; it occurs massive, disseminated, cellular, corroded, &c.

ELEVENTH GENUS. *Antimony.*

First species. Native antimony.

The colour is perfect tin-white; it occurs massive disseminated, reniform, and probably chrystallized.

Species 2.—Grey.
Species 3.—Black.
Species 4.—Red.
Species 5.—White antimony ore.
Species 6.—Antimony-ochre.

TWELFTH GENUS. *Cobalt.*

First species. White cobalt ore.

When fresh fractured the colour is usually tin-white; it occurs massive, disseminated &c.

Second species. Grey cobalt ore.

On the fresh fracture its colour is light steel grey, inclining to white, but it becomes tarnished by exposure.

Third species. Cobalt glance.

The colour is a silver white, slightly inclining to reddish: it is commonly massive and disseminated, sometimes chrystallized in different forms; is externally splendent, internally between shining and glistening, and has a metallic lustre. It is semihard, brittle, not very easily frangible; and when struck with steel, emits an arsenical smell. It is found in veins in various formations, in the different mine countries of the continent of Europe; and from it the greatest part of the cobalt in commerce is obtained, which is highly useful in the manufacture of glass, and as a pigment.

Fourth species. Black cobalt ore.

Earthy black cobalt ore is of an intermediate colour between brownish and bluish-black.

Fifth species. Brown cobalt ochre

Is of a liver-brown colour, passing sometimes into other neighbouring shades; it occurs massive and disseminated.

Sixth species. Yellow cobalt ochre.

Is usually of a dirty straw-yellow, occurs massive, frequently much corroded.

Seventh species Red cobalt ochre.

Cobalt crust is of a peach blossom-red colour.

THIRTEENTH GENUS. *Nickel.*

First species Copper nickel.

Is of a red copper-colour of different degrees of intensity.

Second species. Nickel ochre

Is of an apple-green colour, occurs always as a coating or efflorescence.

FOURTEENTH GENUS. *Manganese.*

First species. Grey manganese ore.

Radiated grey manganese ore is of a dark steel grey colour, occurs massive, disseminated, and chrystallized in prisms of different varieties.

Second species. Black manganese ore.

Is of an intermediate colour between brownish-black and dark-greyish black, occurs massive, disseminated, and in octahedral chrystals.

Third species. Red manganese ore

Is of a light rose-red colour, occurs massive and disseminated.

FIFTEENTH GENUS. *Molybdena.*

First species. Molybdena.

Its colour is a fresh burning lead-grey; it occurs usually massive and disseminated, but also chrystallized in six-sided tables, and short six-sided prisms.

SIXTEENTH GENUS. *Arsenic.*

First species. Native arsenic.

When fresh broken it is of a light whitish lead-grey colour, but it speedily tarnishes; it occurs massive, disseminated, reniform, and in plates, with various impressions.

Second species. Arsenic pyrites.

Common arsenic pyrites is, when fresh, of a silver-white colour, but soon acquires a yellowish tarnish.

Third species. Orpiment

Red orpiment is of an aurora-colour, of different degrees of intensity: it occurs massive, disseminated in membranes.

Fourth species. Arsenic bloom.

The colour is of a reddish-white and snow-white; it occurs as a coating, in small balls, &c.

SEVENTEENTH GENUS. *Scheele.*

First species Tungsten.

The colour is usually yellowish and greyish-white, which pass into several other neighbouring shades.

Second species. Wolfram

Is of an intermediate colour between dark greyish-black and brownish-black; it occurs massive, and also chrystallized in broad six-sided prisms; and rectangular four-sided tables.

EIGHTEENTH GENUS. *Menachine.*

First species. Menachanit.

Is of a greyish-black colour, inclining to iron-black, occurs only in small flattish angular grains.

Second species. Octrahedrite.

Its colour passes from indigo-blue to many other shades; it occurs only chrystallized.

Third species. Rutile

Is of a dark blood-red colour, of various degrees of intensity; it occurs always chrystallized in four-sided and six-sided prisms.

Fourth species. Nigrine

Is of a dark brownish-black colour, passing to velvet-black; it occurs in larger and smaller angular grains, and in rolled pieces.

Fifth species. Iserine.

Is of an iron-black colour, somewhat inclining to brownish black; it occurs usually in small obtuse angular grains, and in rolled pieces, internally glistening, with a semi-metallic lustre, is completety opaque, hard, brittle, and retains its colour in the streak.

NINETEENTH GENUS. *Uran.*

First species. Pitch ore

Is usually of a velvet-black colour; it occurs almost always massive and disseminated.

Second species. Uran mica.

The principal colour is a grass-green, passing into various allied shades; it occurs sometimes in membranes, but commonly chrystallized in rectangular four-sided tables.

Third species. Uran Ochre.

Friable uran ochre is usually of a straw-yellow colour; it generally occurs as coating or efflorescence on pitch ore.

TWENTIETH GENUS. *Sylvan.*

First species. Native Sylvan.

Is of an intermediate colour between white and silver-white: occurs massive, and disseminated, and also chrystallized.

Second species. Graphic ore.

Its colour is a light steel-grey: it occurs massive and chrystallized; externally is splendent, internally glistening.

Third species. Yellow Sylvan ore

Is of a silver-white colour, inclining to brass-yellow; it occurs disseminated, and chrystallized in very small, and rather broad four-sided prisms.

Fourth species. Black Sylvan

Is of an intermediate colour between iron-black, and blackish lead-grey; it occurs massive, and in small, thin, and longish six-sided tables.

TWENTY-FIRST GENUS. *Chromium.*

First species. Acicular, or Needle ore.

Its colour is dark-steel-grey: occurs in imbedded acicular chrystals: internally shines with a metallic lustre, is soft, not very brittle, heavy, and is always accompanied with chrone, ochre, and sometimes with native gold. It is found in Siberia.

Second species. Chrome ochre.

Is of a verdigris-green, passing through several neighbouring shades; it occurs massive disseminated, and in membranes; is dull, soft, not very heavy, and is found with the preceding species

Explanation of the Plates.

PLATE XXXV.

FIG. 1. The Icosahedron.
2. The Dodecahedron.
The Hexahedron, as
3. Cube.
4. Rhomb.
5. Rectangular tetrahedral prism.
6. Oblique-angular tetrahedral prism.
7. Oblique-angular tetrahedral prism, in which the terminal planes are set obliquely on the lateral planes.
8. Equiangular hexahedral prism.
9. Tetrahedron, or simple three-sided pyramid.
10. Double three-sided pyramid, in which the lateral planes of the one pyramid are set on the lateral edges of the other.
11. Octahedron.
12. Simple six-sided pyramid.
13. Double six-sided pyramid, in which the lateral planes of the one pyramid are set on the lateral planes of the other.
14. Double six-sided pyramid, in which the planes of the one pyramid are set obliquely on those of the other, so that the common base forms a zig-zag line.
15. Rectangular four-sided table.
16. Oblique-angular four-sided table.
17. Equiangular six-sided table.
18. Lengthened six-sided table.
19. and 20. Common lens.

Alterations of the Fundamental Figures by Truncation.

21. Cube truncated on all its angles.

PLATE XXXVI.

22. Cube truncated on all its edges.

By Bevelment.

23. The cube bevelled on all its edges.
24. Three-sided prism having its lateral edges bevelled.
25. Oblique-angular four-sided prism bevelled on its extremities.
26. Six-sided table, with bevelled terminal planes.
27. Octahedron, with bevelled angles.

By Acumination.

28. Cube, with the angles acuminated by three planes which are set on the lateral plan.
29. Cube, with the angles acuminated by three planes which are set on the lateral edges.
30. Rectangular four-sided prism acuminated by four planes, which are set on the lateral planes.
31. Equiangular six-sided prism, acuminated on both extremities by six planes, which are set on the lateral planes.

32. Four-sided prism acuminated on both extremities by four planes, which are set on the lateral edges.
33. Six-sided prism, acuminated on both extremities by three planes, which are set on the alternate lateral planes.
34. Six-sided prism, acuminated on both extremities by three planes, which are set on the alternate lateral edges.
35. Double eight-sided pyramids, acuminated on both extremities by four planes, which are set on the alternate lateral edges.

MINIATURE, a delicate kind of painting, distinguished by the smallness of the figures, its being performed with dots or points, instead of lines; by the faintness of the colouring; its requiring to be viewed very near; and by its being usually done on ivory.

MINIMUM, in the higher geometry, the least quantity attainable in a given case. See MAXIMUM.

MINISTER, a person who preaches, performs religious worship in public, administers the sacraments, &c.

MINISTER, *of state*, a person to whom a sovereign prince intrusts the administration of the government.

MINISTER, *foreign*, is a person sent into a foreign country to manage the affairs of his province, or of the state to which he belongs. Of these there are two kinds: those of the first rank are embassadors and envoys extraordinary, who represent the persons of their sovereigns. The ministers of the second rank are the ordinary residents.

MINOR, in law, is an heir, either male or female, before they arrive at the age of twenty-one; during the minority of such, they are usually incapable of acting for themselves.

MINOR, in logic, the second proposition of a regular syllogism.

MINSTREL, in ancient customs, certain persons who combined the character of poet and musician, and whose profession it was to wander about the countries they inhabited, singing panegyrical songs and verses on their occasional benefactors, accompanying them with some musical instrument.

MINT, the place in which the king's money is coined. See COINING.

MINUTE, in geometry, the sixtieth part of degree of a circle.

Minutes are denoted by one acute accent, thus ('); as the second, or sixtieth part of a minute, is by two such accents, thus (".); and the third by three ('''), &c.

MINUTE of time, the sixtieth part of an hour.

MIRACLE, is defined by Dr. Samuel Clark to be a work effected in a manner different from the common and regular method of Providence, by the interposition either of God himself, or some intelligent agent superior to man. The writer, now cited, maintains, that miracles are neither the effects of natural causes, nor of superior created intelligences acting from themselves alone; but that they are always to be ascribed to a divine interposition; *i. e.* that they are never wrought, but either immediately by God himself, or by such other beings as he commissions and empowers to perform them. In proof of this proposition he alleges, that the same arguments which prove the existence of superior created intelligences, do much more strongly conclude against their acting out of their proper sphere. Further, the supposition of the power, of any created agents to work miracles of themselves in this lower world, is contradicted by the observation and experience of all ages; there being, in fact, no proper evidence of the truth of any miracles, but such as may be fitly ascribed to the Deity. The stress usually laid on what is termed the evidence of miracles in favour of the Christian system is certainly too great. The effect of such interpositions is evidently compulsory, not persuasive. This is manifest from their whole history; and particularly so from that part of it which describes their commencement. An ignorant and idolatrous people were at once, as it were, forced into an assembly representative of the true church of God; and a constant succession of miracles was necessary to keep them in this state. This was a very different thing from persuasion; indeed, miracles are expressly said to be "for those who believe not." And, indeed, down to the latest period of their being wrought we find them so generally productive of a hardening and irritating effort on the minds of those who witnessed them, that, on one occasion, at least, *He*, who hath the controul of the universe, is said to have seen it to be necessary to abstain from doing mighty works among the people "*because of their unbelief.*" Nor is this to be wondered at when we consider that the grand end of miracles from first to last, was to shadow forth the nature of the great work of human redemption, effected by Omnipotence, and its application to the regeneration, and consequent salvation of man; for to every exhibition of this wonderful plan of mercy, the human mind has always manifested its aversion.

MIRROR. See OPTICS.

MISCHIEF. Malicious mischief is an injury of such a gross nature, to personal property, that although it is not done with a felonious intention, or an intent to steal, the law has inflicted punishment upon it by various statutes. By statute 6, George I. c. 23, the wilfully and maliciously tearing, cutting, spoiling, or defacing, the garments of any person passing in the streets or highways, and assaulting, with intent to do so, is felony. And there are other acts which relate to the prevention of setting fire to out-houses with corn, damaging fish-ponds, trees planted in gardens, cutting down sea-banks, hop binds, setting fire to mines preventing persons from buying corn, setting fire to goss, furze, &c.; wilfully burning engines in mines, fences in enclosures, breaking into houses of the Plate Glass Company, with intent to destroy utensils; breaking into houses to cut or destroy cloth, serge, linen, &c. in the loom, and other similar offences.

MISCHNAH, or MISNAH, the code or collection of the civil law of the Jews. The Jews pretend that when God gave the written law to Moses, he gave him also another not written, which was preserved by tradition among the doctors of the synagogue, till Rabbi Judah, surnamed the Holy, seeing the danger they were in, through their dispersion, of departing from the traditions of their fathers, judged it proper to reduce them to writing. The Misnah

is divided into six parts: the first relates to the distinction of seeds in a field, to trees, fruits, tythes, &c.; The second regulates the manner of observing festivals; the third treats of women, and matrimonial cases; the fourth of losses in trade, &c. the fifth is on obligations, sacrifices, &c.: and the sixth treats of the several sorts of purification.

MISDEMEANOUR. A crime or misdemeanour is an act committed or omitted, in violation of a public law, either forbidding or commanding it.

MISLETOE. See Viscum.

MISNOMER, the using of one name for another. Where a person is described so that he may not be certainly distinguished and known from other persons, the omission, or in some cases the mistake of the name shall not avoid the grant. But in actions and indictments, &c. the misnomer may be pleaded, and will abate the suit or indictment.

MISPRISION, is generally understood to be of all such high offences as are under the degree of capital, but bordering thereon, and it is said that a misprision is contained in every treason and felony whatsoever; and that if the king please, the offender may be proceeded against for the misprision only.

MISSIONARIES, are those persons who are sent by any Christian church into Pagan or infidel countries, for the purpose of teaching the natives the Christian religion.

The following is a list of the leading institutions among the Protestant churches which have sent out and supported missions among the heathen. The Corporation for the propagation of the gospel in New England, and the adjacent parts of America, erected in 1649. Of this Society the Hon. Mr. Boyle was Governor about 3 years.

The Society in London for promoting Christian knowledge, instituted 1698.

The Society for the Propagation of the Gospel in Foreign Parts, incorporated 1701.

The Society in Scotland for propagating Christian knowledge, incorporated 1709.

The Royal Danish Mission College.

The Moravians, or United Brethren, 1732.

The Methodist Missionary Society, 1786.

The Baptist Missionary Society, instituted 1792.

The London Missionary Society, instituted 1795.

The Edinburgh (now the Scottish) Missionary Society, instituted 1796.

The Church of England Missionary Society instituted 1799.

The American Board of Commissioners for Foreign Missions, instituted 1810.

The Baptist American Board of Commissioners for Foreign Missions, instituted 1814.

MISSIVE, something sent to another, as missive letters; meaning letters sent from one to another upon business, in contra-distinction to letters of gallantry, points of learning, dispatches, &c.

MITCHELLA, in botany, so named from John Mitchell, M. D. a physician, in Virginia, a genus of the tetrandria monogynia class and order. The cor. is 1-petalled; stigmas 4; berry trifid, 2-seeded. There is one species, an herb of N. America.

MITE, a small coin formerly current, equal to about one third part of a farthing. It also denotes a small weight used by the moneyers. It is equal to the twentieth part of a grain, and is divided into twenty-four doits.

Mite. See Acarus.

MITRE, a sacerdotal ornament worn on the head by bishops, and certain abbots, on solemn occasions; being a sort of cap, pointed, and cleft at top. The high priest among the Jews wore a mitre or bonnet on his head. The inferior priests among the Jews had likewise their mitres, but in what respect they differed from that of the high priest is uncertain. Some contend that the ancient bishops wore mitres, but this is by no means certain. Those young women among the primitive Christians who professed a state of virginity, and were solemnly consecrated thereto, wore a purple and golden mitre as a badge of distinction.

MITTIMUS, a writ by which records are transferred from one court to another. This word is also used for the precept directed to a gaoler, under the hand and seal of a justice of the peace, for the receiving and safe keeping a felon, or other offender, by him committed to gaol.

MIZEN, in the sea-language, is a particular mast or sail. The mizen-mast stands in the sternmost part of the ship. Its length is by some accounted the same with the height of the main-top-mast, from the quarter-deck; or half the length of the main-mast, and half as thick. The sail which belongs to the mizen-mast, is called the mizen-sail: and when the word mizen is used at sea, it always means the sail.

MINIUM, in botany, a genus of the cryptogamia musci class and order. Nat. order of mosses: capsule with a lid; calyptre smooth; bristle from a terminating tubercle: male flowers headed, or discoid. M. *hygrometricum* is the most remarkable species. If the fruit-stalk be moistened at the bottom, the head makes three or four turns; and if the head be moistened, it turns the contrary way.

MOAT, or Ditch, in fortification, a deep trench dug round the rampart of a fortified place. The brink next the rampart is called the scarp; and the opposite one, the counterscarp. A dry moat round a large place, with a strong garrison, is preferable to one full of water, because the passage may be disputed inch by inch. In the middle of dry moats, there is sometimes another small one, called a cunette; which is generally dug so deep, till they find water to fill it.

MODE, in logic, called also syllogistic mood, a proper disposition of the several propositions of a syllogism, in respect of quantity and quality.

Mode, in philosophy, denotes the manner of a thing's existence.

Mode, in music, a particular manner of constituting the octave; or, the melodious constitution of the octave, as it consists of seven essential sounds, besides the key of fundamental.

MODEL, in a general sense, an original pattern, proposed for any one to copy or imitate. This word is particularly used in building, for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better conducting and executing some great work, and to give an idea of the effect it will have

They also use models in painting and sculpture; whence, in the academies, they give the term model to a naked man or woman, disposed in several postures, to afford an opportunity to the scholars to design him in various views and attitudes. Models in imitation of any natural or artificial substance, are most usually made by means of moulds composed of plaster of Paris. When a model is to be taken, the surface of the original is first to be greased, in order to prevent the plaster from sticking to it. The original is then to be laid on a smooth table, previously greased, or covered with a cloth, to prevent the plaster sticking to it; then surround the original with a frame or ridge of glazier's putty, at such a distance from it as will admit the plaster to rest upon the table, on all sides of the subject for about an inch, or as much as is sufficient to give the proper degree of strength to the mould. A sufficient quantity of plaster is then to be poured as uniformly as possible over the whole substance, until it is every where covered to such a thickness as to give a proper substance to the mould, which may vary in proportion to the size. The whole must then be suffered to remain in this condition till the plaster has attained its hardness. When the frame is taken away, the mould may be inverted, and the subject removed from it; and when the plaster is thoroughly dry, let it be well seasoned.

MODILLIONS, in architecture, ornaments in the corniche of the Ionic, Corinthian, and Composite columns. They are little inverted consoles, or brackets, in form of an S, under the soffit of the corniche, seeming to support the projecture of the larmier, though in reality they are no more than ornaments.

MODULATION, in music, the art of conducting harmony, in composition, or extemporary performance, through those keys and modes which have a due relation to the fundamental, or original key.

MODULE. See Architecture.

MODUS DECIMANDI, in law, is where money, land, or other valuable consideration, has been given, time out of mind, to the minister or parson of any certain place, in the room of tithes.

MOERHINGIA, mossy chickweed, in botany, a genus of the octandria digynia class of plants, the flower of which is composed of four short, undivided petals; and its fruit is a subglobose capsule, with one cell, in which are contained numerous roundish seeds. There is one species.

MOHAIR, in commerce, the hair of a kind of goat, frequent about Angora, in Turkey; the inhabitants of which city are all employed in the manufacture of camblets, made of this hair.

MOISTURE, a term sometimes used to denote animal fluids, the juices of plants, or dampness of the air, or other bodies.

MOLE. See Talpa.

MOLE-CRICKET. See Gryllus.

MOLLUGO, in botany, a genus of the triandria trigynia class and order. Nat. ord. caryophyllei. Calyx, five-leaved; corolla, none; capsule, three-celled, three-valved. There are six species, annuals of warm countries.

MOLLUSCA, in natural history, the second order of the Linnæan class vermes. They are naked; furnished with tentacula, or arms; for the most part inhabitants of the sea; and by their phosphoreous quality, illuminate the dark abyss of the waters. This order, comprised of simple animals furnished with limbs, is distinguished in the following way: A, mouth placed above; B, mouth placed before; C, mouth placed before; body with a lateral perforation; D, mouth before: body surrounded with feelers on the fore part; E, mouth before, body furnished with arms; F, mouth before: body furnished with peduncles or feet; G, mouth placed beneath, and generally central.

MOLOSSES, in commerce, the thick fluid matter remaining after the sugar is made, resembling syrup. See Sugar.

MOLTING, the change of feathers, hairs, or horns, in birds and beasts.

MOLYBDATES, in chemistry, salts formed from the molybdic acid and the earths, alkalies, &c. They are mostly colourless, and soluble in water; they have a metallic taste. The prussiate of potash throws down from several of them a light brown coloured precipitate.

MOLYBDENUM. A metal which has not yet been reduced into masses of any magnitude; but has been obtained only in small separate globules, in a blackish brilliant mass. This may be effected by making its acid into a paste with oil, bedding it in charcoal in a crucible, and exposing it to an intense heat. The globules are grey, brittle, and extremely infusible. By heat it is converted into a white oxide, which rises in brilliant needle-formed flowers, like those of antimony. Nitric acid readily oxidizes and acidifies the metal. Nitre detonates with it, and the remaining alkali combines with its oxide.

Molybdenum unites with several of the metals, and forms brittle or friable compounds. No acid acts on it but the nitric and nitromuriatic. Several acids act on its oxide, and afford blue solutions. See Acid (Molybdic.)

The sp. gr. of molybdenum is 8.611. When dry molybdate of ammonia is ignited in a crucible with charcoal powder, it is converted into the brown oxide of the metal. This has a crystallized appearance, a copper-brown colour, and a sp. gr. of 5.66. It does not form salts with acids. The deutoxide is molybdous acid, which see.

MOMENT, in the doctrine of infinites, denotes the same with infinitesimal.

Moment, *momentum*, in mechanics, signifies the same with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter, multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity.

MONADELPHIA, (from *μονος alone*, and *αδελφια* a *brotherhood;*) a "single brotherhood." The —— of the 16th class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers; in which all the stamina, or male organs of generation, are united below into one body or cylinder, through which passes the pointal or female organ. See Botany.

MONANDRIA, (from *μονος alone*, and *ανηρ man* or *husband,)* the name of the first class in Linnæus's sexual system; consisting of plants with hermaphrodite flowers, which have only one stamen or male organ.

MONARCHY, a government in which the supreme power is invested in a single person. There are several kinds of monarchies, as where the monarch is invested with an absolute power, and is accountable to none but God. Another kind of monarchy is that which is limited, where the supreme power is virtually in the laws, though the majesty of government and the administration is vested in a single person. Monarchies are also either hereditary, where the regal power descends immediately from the possessor to the next heir by blood; or elective, where the choice depends upon all who enjoy the benefit of freedom, or upon a few persons in whom the constitution vests the power of election.

MONAS, a genus of vermes, order infusoria. The generic character is, worm invisible to the naked eye, most simple, pellucid, resembling a point. There are five species.

MONEY, a substance, commonly metal, and generally of a determined shape and weight, to which public authority has affixed a certain value to serve as a medium in commerce. Money is usually divided into real or effective; and imaginary, or money of account.

Real money includes all coins, whether of gold, silver, copper, or the like. Imaginary money, or money of account, is that which never existed, or at least, which does not exist in real specie; but is a denomination invented or retained to facilitate the stating of accounts, by keeping them still on a fixed footing, not to be changed like current coins.

No person is obliged to take in payment any money which is not lawful metal, that is, of silver and gold, except for sums under sixpence. But it was decided in 1790, that bank-notes were considered as money, and therefore a proper tender in payment.

English Money *of account*, is the pound, shilling, and pence; the pound contains twenty shillings, and the shilling twelve pence.

The old Scotch Money *of account* was the pound, shilling, and penny; the pound containing twenty shillings, being equivalent to one shilling and eightpence English; and the shilling containing twelve pennies, equal to a penny English. There is also among them an account of marks, the mark being equivalent to one shilling 1⅓ penny English: of this last kind they had formerly a silver coin.

Money *bringing into court*. In some actions at law the defendant is allowed to pay a sum into court, which he contends is the fair amount of the plaintiff's just demand, and the plaintiff will afterwards proceed at his peril. This can only be done where the damages can readily be ascertained in money.

MONKEY. See Simia.

MONOCHORD, a musical instrument, composed of one string, used to try the variety and proportion of sounds. It is formed of a rule, divided and sub-divided into several parts, on which there is a moveable string stretched upon two bridges at each extreme. In the middle between these is a moveable bridge, by means of which, in applying it to the different divisions of the line, the sounds are found to bear the same proportion to each other as the division of the line, cut by the bridge.

MONOCULUS, in natural history, a genus of insects of the order Aptera. Legs four to eight, formed for swimming, and very long; body covered with a crest, or shell, divided into segments; antennæ sometimes four, sometimes two, and sometimes without any; four feelers, in continual motion when swimming, the hind ones very small, and hook-shaped. There are about 50 species, separated into sections. A. With a single eye, and crustaceous body. B. With a single eye, and bivalve shell; antennæ branched. C. With a single eye, and bivalve shell; antennæ simple. D. With a single eye, and bivalve shell; antennæ tufted at the tip. E. With a single eye, and univalve shell; antennæ two. F. Shell univalve; two eyes placed beneath. G. Shell bivalve; eyes two, placed on the back. The greater part of the monoculi are very small water insects, requiring the assistance of the microscope for the investigation of their particular organs. To this there is, however, an exception in the M. *polyphemus*, which inhabits India. This is distinguished by the title of the Molucco crab, or king crab, and grows sometimes to the length of four feet. In this species the eyes, instead of being approximated, as is required in the Linnæan generic character, are extremely distant from each other, being situated towards the sides of the shell. "The whole structure of this animal is very remarkable and particularly his eyes, which are between the fourth and last pair of claws on each side, reckoning from his mouth, and excluding the small pair there placed, are inserted the rudiments of another pair, or a claw broken off on each side at the second joints or elbow; on these extremities are the eyes like those of the horns of snails; but under the covert of a thick and opaque shell nature in that place has wonderfully contrived a transparent lantern, through which the light is conveyed."

MONODON, the *narwhal*, in natural, history a genus of mammalia of the order cetæ. Generic character: tooth (sometimes two teeth) in the upper jaw, projecting straight forward, long and spiral; spiracle on the head. The only species of this genus is M. *monoceros*, or the unicorn narwhal; this is found in northern seas, and generally of the length of twenty feet from the mouth to the tail; from a socket in the upper jaw on one side, a tooth somewhat resembling a horn grows, in a perfectly straight direction, and a wreathed or screw-like form, to the length of six, and occasionally nine or ten feet, of a light yellow colour, and terminating in a sharp point, a circumstance by which it is discriminated from every other species of whales. The incipient protrusion of a second tooth on the other side of the jaw is generally perceivable, and in some instances, though rarely, both advance to maturity. The narwhals subsist principally upon flat fish. They are seldom observed in the open sea, and frequent the unfrozen spots near the coast of the arctic regions. They are taken by the Greenlanders in great abundance by the harpoon; their flesh is eaten prepared in various ways, and the oil and intestines are also articles in great request. The tendons are split into thin fibres, serving the purposes of thread, and the teeth are used sometimes for hunting horns, and more frequently as pillars and gate-posts in houses.

These horns were formerly considered as indicative of royal state and magnificence, being employed as the ornaments of palaces.

MONOECIA, from *μονος alone*, and *οικια a house*: the name of the 21st class of Linnæus's sexual method. See BOTANY.

MONOGRAM, a character or cypher, composed of one, two, or more letters, interwoven; being a kind of abbreviation of a name, anciently used as a seal, badge, arms, &c. The use of arms is very ancient, as appears from Plutarch, and from some Greek medals of the time of Philip of Macedon and Alexander his son. The Roman labarum bore the monogram of Jesus Christ, which consisted of two letters, a P placed perpendicularly through the middle of an X, as we find it on many medals in the time of Constantine, these being the two first letters of the word ΧΡΙΣΤΟΣ. Thus under the eastern empire it is usual to find MIK, which are the monogram of Mary, Jesus, Constantine.

MONOGYNIA from *μονος alone*, and *γυνη a woman*: the name of the first order or subdivision in the first 13 classes of Linnæus's sexual method; consisting of plants, which have only one style, or female organ.

MONOTONY, an uniformity of sound, or a fault in pronunciation, when a long series of words are delivered in one unvaried tone.

MONSOON, in physiology, a species of trade wind, in the East Indies, which for six months blows constantly the same way, and the contrary way the other six months. However, it ought to be observed, that the points of the compass from whence the monsoons blow, as well as the times of their shifting, differ in different parts of the Indian ocean. The cause of monsoons is this: when the sun approaches the northern tropic, there are countries, as Arabia, Persia, India, &c. which become hotter, and reflect more heat than the seas beyond the equator, which the sun has left; the winds therefore, instead of blowing from thence, to the parts under the equator, blow the contrary way; and, when the sun leaves those countries, and draws near the other tropic, the winds turn about, and blow on the opposite point of the compass.

MONTH, in chronology, the twelfth part of a year. An astronomical month is that which is governed either by the motion of the sun or moon, and is consequently of two kinds, solar and lunar: a solar month is that time in which the sun seems to run through a whole sign, or the twelfth part of the ecliptic. The real mean quantity of a solar month is 30 days, 10 hours, 29 minutes, 5 seconds. A lunar month is that space of time which the moon takes up in performing its course through the zodiac, or that measured by the motion of the moon round the earth; and is of 3 kinds, viz. periodical, synodical, and that of illumination. The lunar periodical month, is the space of time wherein the moon makes her round through the zodiac, or wherein she returns to the same point, being 27 days, 7 hours, 43 minutes, and 5 seconds. The lunar synodical month, called also absolutely the lunar month and lunation, is the space of time between two conjunctions of the moon with the sun; or the time it takes from one conjunction with the sun to the next; or from one new moon to another.

A civil or political month, consists of a certain number of days according to the laws and customs of the different countries wherein it is used, either having no regard to the solar or lunar months, as those of the Egyptians in their equal year; of the Romans in the year of Romulus, &c.; or coming pretty near to the solar astronomical month, as the Julian, or else the lunar astronomical as the Jewish, Turkish, and others.

Civil solar months, are such civil months as are accommodated to the astronomical months, or those which are to consist alternately of thirty and thirty-one days, excepting one month of the twelve, which, for every fourth year, consisted of thirty days, and for the other years of twenty-nine. This form of civil months was introduced by Julius Cæsar; but under Augustus the sixth month, till then, from its place, called Sextilis, was denominated Augustus, in honour of that prince; and to make the compliment yet the greater, a day was added to it, so that it now consists of thirty-one days, to make up for which a day was taken from February, so that from thenceforward it only consisted of twenty-eight days, and every fourth year of twenty-nine: though before it had ordinarily consisted of twenty-nine days, &c. and such are the civil or calender months which now obtain throughout Europe.

Civil lunar months are to consist alternately of twenty-nine and thirty days: thus will two civil months be equal to two astronomical ones, abating for the odd minutes, and consequently the new moon will be hereby kept to the first day of each such civil month, for a long time together. However, to make them keep constantly pace with the civil months, at the end of each nine hundred and forty-eight months, a month of twenty-nine days must be added; or else every thirty-third month must consist of thirty days. This was the month in civil or common use among the Jews, Greeks, and Romans, till the time of Julius Cæsar.

MONTIA, water chickweed, a genus of the trigynia order, in the triandria class of plants; and in the natural method ranking with those two of which the order is doubtful. There is one species.

MOOD, or *Mode*, in grammar, the different manner of conjugating verbs, serving to denote the different affections of the mind.

MOON. See ASTRONOMY.

MOONSTONE. This is the purest felspar hitherto found. It occurs in Ceylon and Switzerland; colour white; sometimes with a shade of yellow, green, or red.

MOORING, in the sea-language, is the laying out the anchors of a ship in a place where she can ride secure. Mooring across, is laying out on each side; and mooring along, is to have an anchor in a river and a hawser on shore.

MORAVIANS, HERRNHUTTERS, or UNITAS FRATRUM, in church history, a denomination of Christians, concerning whose origin, history, and character, various contradictory reports have been published. The church of the United Brethren is episcopal, and their church government is conducted with great form and regularity. Questions of dispute are settled by ballot, and in cases

of real or supposed importance are often decided by lot. The lot is deemed a solemn appeal to heaven, and is made use of with great seriousness. They have œconomies, or choir-houses, where they live together in community: the single men and single women apart, widows and widowers apart, each under the superintendance of elderly persons of their own class. The Moravians are very strict in their attention to the youth of both sexes, and never suffer them to come together or to marry without the previous consent of the church; and as the lot must be cast to sanction their union, each receives his partner as a divine appointment. Though the Moravians are united in one body, they are by no means illiberal in their views towards other christians, who hold what they conceive to be the essentials of religion, and pay divine adoration to Jesus Christ. In doctrine they appear to be inclined to Sabellianism. They address all their prayers to Jesu, or the Lamb, and they have been accused, not without reason, of adopting a phraseology in their hymns and prayers not consistent with the rules of decency and chastity. They are, however, a very harmless and unoffending people. They appear to be Arminians in opposition to Calvinism, and they reject the use of the term trinity, and some other popular terms and phrases.

MORDANT. In dyeing, the substance combined with the vegetable or animal fibre, in order to fix the dye stuff. It also usually modifies the colour.

MORDELLA, a genus of insects of the order coleoptera. The antennæ are thread-shaped and serrated: the head is deflected under the neck: the pappi are elevated, compressed, and obliquely blunted; and the elytra are bent backwards near the apex. There are six species.

MORMYRUS, a genus of fishes of the branchiostegeous order, the generic character is, head smooth; teeth numerous, notched; aperture of the gills linear, without a cover; gill membrane with one ray; body scaly. There are three species. The kannume has the tail bifid, obtuse; dorsal fin with 63 rays It inhabits the Nile.

MOROCCO, *maroquin*, in commerce, a fine kind of leather prepared of the skin of an animal of the goat-kind, and imported from the Levant, Barbary, &c.

MOROXYLATES, in chemistry, a genus of salts, of which there are two species, viz. 1. The moroxylate of lime found on the bark of mulberry-trees, chrystallized in short needles. Its taste resembles succinic acid. When heated it swells and emits a vapour which irritates the organs of smell. Its solution precipitates acetate of lead, nitrate of silver, and nitrate of mercury. 2. M. of ammonia, obtained by pouring carbonate of ammonia into the solution of the moroxylate of lime. This solution when evaporated, yields chrystals of moroxylate of ammonia in long, slender prisms.

MOROXYLIC *acid*, discovered by Dr. Thompson on the bark of the *morus alba* or white mulberry, growing at Palermo in Sicily. It has the taste of succinic acid; is not altered by exposure to the air; but dissolves readily in water and alcohol. It does not precipitate the metallic solutions like its salt.

MORTALITY, *bills of*, registers of the number of deaths or burials in any parish or district. The establishment of bills of mortality in great Britain, originated in the frequent appearance of the plague, which formerly made great devastations in this country, and an abstract of the number of deaths was published weekly, to shew the increase or decrease of the disorder, that individuals might not be exposed to unfounded alarms, but have some means of judging of the necessity of removal, or of taking other precautions, and government to be informed of the propriety or success of any public measures relating to the disorder.

The London bills of mortality are founded upon the reports of the sworn searchers, who view the body after decease, and deliver their report to the parish clerk. The parish clerks are required under a penalty for neglect, to make a weekly return of burials, with the age and disease of which the person died; a summary of which account is published weekly; and on the Thursday before Christmas-day, a general account is made up for the whole year.

The total number of parishes now comprehended in the London bills of mortality is 146. They are divided into the ninety-seven parishes within the walls, sixteen parishes without the walls, twenty-three out-parishes in Middlesex and Surrey, and ten parishes in the city and liberties of Westminster. They give the ages at which the persons die, and a list of the diseases and casualties by which their death was occasioned, but little dependence canbe placed on the list of diseases, except with respect to some of the most common and determinate. These bills would afford the means of ascertaining the state of population with sufficient precision, if the proportion of annual deaths to the number of the living could be accurately determined

MORTAR, a preparation of lime and sand mixed up with water, which serves as a cement, and is used by masons and bricklayers in building of walls of stone and brick. The best mortar for resisting water is made by mixing with lime, puzzolano, a volcanic sand brought from Italy. Basaltes may be substituted in its stead.

Mortar, in chemistry and pharmacy, an utensil very useful for the division of bodies by percussion, trituration, &c. Mortars are of different shapes and sizes, and the matter intended to be broken in them is struck with a pestle made of wood, iron, or marble, according to the different degrees of hardness.

Mortar, *piece*, a short piece of ordnance, considerably thick and wide; serving to throw bombs, carcasses, fire-pots, &c.

In shooting with mortars, the following general rules should be always observed. 1. To measure the distance of the object aimed at. 2. That the bombs be of equal weight, otherwise the shots will vary. 3. That the carriage be on an exact level, to prevent its leaping. 4. That the powder with which the piece is charged, be always of the same strength and quantity. 5. That the charge be equally rammed down. 6. That the wads be always of wood, tompions, or oakum. 7. That the fusees be fresh made the days on which they are to be used; and that

they be of a composition proportionable to the range of the shot in the air, so that the bomb may break at the very moment of, or soon after its fall; which composition must be such as not to be extinguished, though it fall in water, but continue burning till the bomb breaks.

MORTGAGE, signifies a pawn of lands or tenements, or any thing immoveable, laid or bound for money borrowed, to be the creditor's for ever, if the money be not paid at the day agreed upon. Mortgages are neither in fee, or for term of years, and the mortgager was formerly considered as tenant at will to the mortgagee, but he is now considered to have no legal estate whatever in the land. The last and best improvement of mortgages is the mode now adopted, where the mortage is made for a term of years, that the mortgager if he has also the fee covenants to convey the fee to the mortgager and his heirs, or any person whom he may appoint, in case of default in payment of the money. Although after breach of the condition, the estate is absolute at common law in the mortgagee; yet a right of redemption subsists in equity, which is called the equity of redemption, from the benefit of which the heir of the mortgager cannot be excluded by any covenant, provided the original intent is to mortgage the estate, and not to sell it at first. Although therefore the mortgage is forfeited, yet a court of equity will allow the mortgager at any reasonable time, to recal or redeem the estate, paying the principal, interest, and costs. This, however, is not allowed if the mortgagee has been twenty years in possession. The heir at law may have the mortgage redeemed out of the personal assets in the first place, as far as they will extend. This privilege is also allowed to the person to whom land mortgaged is devised. Where a mortgager conceals prior incumbrances upon making a second mortgage, he loses the equity of redemption.

MORTISE, or MORTOISE, in carpentry, &c. a kind of joint, wherein a hole of a certain depth is made in a piece of timber, which is to receive another piece called a tenon.

MORTMAIN, signifies an alienation of lands and tenements, to any guild, corporation, or fraternity, and their successors, as bishops, parsons, vicars, &c. which may not be done without the king's licence, and the lord of the manor; or of the king alone, if it is immediately holden of him.

MORUS, the MULBERRY-TREE, a genus of the tetrandria order, in the monœcia class of plants; and in the natural method ranking under the 53d order, scabridæ. The male calyx is quadripartite; and there is no corolla: the female calyx is tetraphyllous; there is no corolla: two styles; the calyx like a berry, with one seed. There are seven species, viz. 1. The *nigra*, or common black fruited mulberry-tree, rises with an upright, large, rough trunk, dividing into a branchy and very spreading head, rising 20 feet high or more. 2. The *alba*, or white mulberry-tree, rises with an upright trunk, branching 20 or 30 feet high. There is a variety with purplish fruit. 3. The *papyrifera*, or paper mulberry-tree of Japan, grows 20 or 30 feet high; having large palmated leaves, some trilobate, others quinquelobed· and monœcious flowers, succeeded by small black fruit. 4. The *rubra*, or red Virginia mulberry-tree, grows 30 feet high; and has large reddish berries. 5. The *tinctoria*, dyer's mulberry, or fustic, has oblong leaves, more extended on one side at the base, with axillary thorns. It is a native of Brasil and Jamaica. 6. The *Tartarica*, or Tartarian mulberry, has ovate oblong leaves, equal on both sides, and equally serrated. It abounds of the banks of the Wolga and the Tanais. 7. The *Indica* or Indian mulberry, has ovate oblong leaves, equal on both sides, but unequally serated. Considered as fruit-trees, the nigra is the only proper sort to cultivate here; the trees being not only the most plentiful bearers, but the fruit is larger and much finer-flavoured than that of the white kind.

Mulberry-trees are noted for their leaves affording the principal food of that valuable insect the silk worm. The leaves of the alba, or white species, are preferred for this purpose in Europe; but in China where the best silk is made, the worms are said to be fed with those of the morus Tartarica. The advantages of white mulberry trees are not confined to the nourishment of worms: they may be cut every three or four years like sallows and poplar-trees to make faggots; and the sheep eat their leaves in winter, before they are burnt. This kind of food, of which they are extremely fond, is very nourishing; it gives a delicacy to the flesh, and a fineness and beauty to the wool.

The *papyrifera*, or paper-mulberry, is so called from the paper chiefly used by the Japanese being made of the bark of its branches. The leaves of this species also serve for food to the silk-worm, and it is now cultivated with success in France. It thrives best in sandy soils, grows faster than the common mulberry, and at the same time is not injured by the cold.

MOSAIC, or MOSAIC-WORK, an assemblage of little pieces of glass, marble, precious stones, &c. of various colours, cut square, & cemented on a ground of stucco, in such a manner as to imitate the colours of painting.

MOSCHUS, musk, a genus of quadrupeds of the order pecora: the generic character is, horns none; front teeth in the lower jaw eight: tusks solitary, in the upper jaw exserted.

1. *Moschus moschiferus*, Tibetian musk. The size and general appearance of this animal resemble those of a small roe-buck. It measures about three feet three inches in length, about two feet three inches in height from the top of the shoulders to the bottom of the fore-feet, and two feet nine inches from the top of the haunches to the bottom of the hind feet. The upper jaw is considerably longer than the lower, and is furnished on each side with a curved tusk about two inches long. These tusks are of a different form from those of any other quadruped; being sharp-edged on their inner or lower side, so as to resemble in some degree a pair of small crooked knives: their substance is a kind of ivory, as in the tusks of the babyrussa and some other animals. The general colour of the whole body is a kind of deep iron-grey. the tips of the hairs being of a ferruginous cast. The remainder blackish, growing much paler or whiter towards the roots. The female is smaller than the male, and wants the tusks; it has also two small teats

They are hunted for the sake of their well-known perfume: which is contained in an oval receptacle about the size of a small egg, hanging from the middle of the abdomen, and peculiar to the animal. This receptacle is found constantly filled with a soft unctuous, brownish substance, of the most powerful and penetrating smell and which is no other than the perfume in its natural state As soon as the animal is killed the hunters cut off the receptacle or musk-bag, and tie it up ready for sale. As musk is an expensive drug, it is frequently adulterated by various substances. As a medicine it is held in high estimation in the Eastern countries, and has now been introduced into pretty general use, especially in those disorders which are commonly termed nervous: and in convulsive and other cases, it is often exhibited in pretty large doses with great success.

2. *Moschus Indicus*, or the Indian musk. This species is rather larger than the common or Tibetian musk, of the colour mentioned in the specific character, with the head shaped like that of a horse, upright oblong ears, and slender legs.

3. *Moschus pygmæus*, or the pigmy musk, is considerably smaller than a domestic cat, measuring little more than nine inches from the nose to the tail. Its colour is bright bay, white beneath, and on the insides of the thighs. Its shape is beautiful, and the legs are so slender as not to exceed the diameter of a swan-quill; the head is rather large, and the aspect mild. It is a native of many parts of the East Indies and the Indian Islands, and is said to be most common in Java.

MOSQUE, a temple or place of religious worship among the Mahometans. All mosques are square buildings, generally built with stone; before the chief gate there is a square court, paved with white marble, and low galleries round it, whose roof is supported by pillars. In these galleries the Turks wash themselves before they go into the mosque. In each mosque there are a great number of lamps. As it is not lawful to enter the mosque with shoes or stockings on, the pavements are covered with pieces of stuff sewed together, each wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter the mosques. About every mosque there are six high towers, called minarets, each of which has three little open galleries, one above another; whence instead of a bell, the people are called to prayer by certain officers appointed for that purpose. Most of the mosques have a kind of hospital belonging to them, in which travellers of what religion soever, are entertained during three days. Each mosque has also a place called tarbe, which is the burying place of its founders; within which is a tomb six or seven feet long, covered with green velvet or satin, at the ends of which are two tapers, and round it several seats for those who read the Koran, and pray for the souls of the deceased.

MOSS. See Muscus.

MOTACILLA, the *wagtail* and *warbler*, a genus of birds of the order of passeres, distinguished by a straight weak bill of a subulated figure, a tongue lacerated at the end, and very slender legs.

1. The *alba* or white wagtail, frequents the sides of ponds and small streams, and feeds on insects and worms. The head, back, and upper and lower side of the neck as far as the breast are black; in some the chin is white, and the throat marked with a black crescent; the breast and belly are white. The tail is very long, and always in motion.

2. The *flava*, or yellow wagtail, migrates in the north of England, but in Hampshire, continues the whole year. The male is a bird of great beauty; the breast, belly, thighs, and vent-feathers, being of a most vivid and lovely yellow. The colours of the female are far more obscure than those of the male: it wants also those black spots on the throat.

3. The *regulus*, or gold-crested wren, is a native of Europe, and of the correspondent latitudes of Asia and America. It is the least of all the European birds, weighing only a single drachm. Its length is about four inches and a half, and the wings when spread out measure little more than six inches. On the top of its head is a beautiful orange coloured spot, called its crest which it can hide, with pleasure.

4. The *sutoria*, or taylor-bird, is a native of the East Indies. It is remarkable for the art with which it makes its nest, seemingly in order to secure itself and its young, in the most perfect manner possible, against all danger from voracious animals. It picks up a dead leaf, and sews it to the side of a living one; its slender bill is the needle, and its thread is formed of some fine fibres: the lining is composed of feathers, gossamer, and down.

5. The *luscinia*, or nightingale, exceeds in size the hedge-sparrow. The bill is brown; the irides are hazel; the head and back pale tawny, dashed with olive; the tail is of a deep tawny red; the under parts pale ash colour, growing white towards the vent; the quills are cinereous brown. The male and female are very similar. This bird the most famed of the feathered tribe for the variety, length, and sweetness of its notes, is supposed to be migratory. The female builds in some low bush or quickset hedge, well covered with foliage, for such only this bird frequents; and lays four or five of a greenish brown. The nest is composed of dry leaves on the outside, mixed with grass and fibres, lined with hair or down within, though not always alike. The female alone sits on and hatches the eggs, while the male not far off regales her with his delightful song, but as soon as the young are hatched he commonly leaves off singing, and joins with the female in the task of providing for and feeding them.

6. The *modularis*, or hedge-sparrow, a well-known bird, has the back and wing-coverts of a dusky hue, edged with reddish brown; rump of a greenish-brown; throat and breast of dull-ash-colour; the belly a dirty white; and the legs of a dull flesh-colour. The note of this bird would be thought pleasant, did it not remind us of the approach of winter.

7. The *phœnicurus*, or redstart, is somewhat less than the red-breast; the forehead is white; the crown of the head, hind part of the neck and back, are deep blue-grey; the cheeks and throat black; the breast, rump, and sides, red; and the belly is white; the two middle tail feathers are brown; the rest red; and the legs are black. The wings are brown in both sexes. This bird is migratory; coming hither in spring, and departing in autumn about October.

Their song has no great strength; yet it is agreeable enough; and they will, if taught young, imitate the notes of other birds, and sing by night frequently as well as in the daytime.

8. The *rubecula*, or red-breast, is universally known. It builds not far from the ground if in a bush; though sometimes it fixes on an outhouse, or retired part of some old building. The nest is composed of dried leaves, mixed with hair and moss, and lined with feathers. The eggs are of a dusky white, marked with irregular reddish spots: and are from three to seven in number. Insects are their general food; but in defect of these they will eat many other things. No bird is so tame and familiar as this; closely attending the heels of the gardener when he is using his spade, for the sake of worms; and frequently in winter entering houses where windows are open, when they will pick up the crumbs from the table while the family is at dinner. Above 150 other species, besides varieties, are enumerated by ornithologists.

MOTE, in law-books, signifies court, meeting, or convention, as a ward mote, burghmote, swain mote, &c.

MOTH. See Phalæna.

MOTION, has been defined to be a "change of place," or the act by which a body corresponds with different parts of space at different times. We are principally acquainted with two sorts of motion in the beings that surround us; one is the motion by which an entire body is transferred from one place to another, as that of a stone when it falls, or of a ship under sail. But, besides this, there is another kind of motion, which, though not so obvious, is yet not less common nor important. This is a motion of the parts of bodies among themselves, which though sometimes the object of our senses, yet in other cases we require the aid of reflection to be convinced of its existence. It is by this imperceptible motion that plants and animals grow, and by which the greatest number of the compositions and decompositions throughout the globe take place. The particles of the most solid bodies are also continually changing their situations. Heat expands, and cold contracts the size of all bodies. Now, we know from experience, that the temperature of bodies is constantly varying, consequently, the particles must be in continual agitation, in order to adapt themselves to the size of the body.

In considering motion, several circumstances must be attended to:

1. The force which impresses the motion.
2. The quantity of matter in the moving body.
3. The velocity and direction of the motion.
4. The space passed over by the moving body.
5. The time employed in going over this space.
6. The force with which it strikes another body that is opposed to it.

In a mechanical sense, every body, by its inertia, resists all change of state. If at rest, it will not begin to move of itself; and if motion is communicated to it by another body, it will continue to move for ever uniformly, except it is stopped by an external agent. It is true, we do not see any instances of bodies continuing to move for ever, after being once put in motion; but the reason of this is, that all the bodies which we see are acted upon in such a manner, as to have their motion gradually destroyed by friction, or the rubbing of other bodies upon them. For, if you diminish the friction by any means, the motion will continue much longer; but as it is impossible to destroy it entirely, it diminishes, and at last destroys, all motions on the surface of the earth. To put a body in motion, therefore, there must be a sufficient cause. These causes are called motive powers, and the following are those generally used in mechanics: the action of men and other animals, wind, water, gravity, the pressure of the atmosphere, and the elasticity of fluids and other bodies.

The velocity of motion is estimated by the time employed in moving over a certain space, or by the space moved over in a certain time. To ascertain the degree of this swiftness or velocity, the space run over must be divided by the time. For example: suppose a body moves over 1000 yards in 10 minutes, its velocity will be 100 yards per minute. If we would compare the velocity of two bodies A and B, of which A moves over 54 yards in 9 minutes, and B 96 yards in 6 minutes, the velocity of A will be to that of B, in the proportion of 6 (the quotient of 54 divided by 9) to 16 (the quotient of 96 divided by 6.)

To know the space run over, the velocity must be multiplied by the time; for it is evident, that if either the velocity or the time is increased, the space run over will be greater.

A body in motion must every instant tend to some particular point. It may either tend always to the same point, in which case the motion will be in a straight line: or it may be continually changing the point to which its motion is directed, and this will produce a curvilinear motion.

If a body is acted upon only by one force, or by several in the same direction, its motion will be in the same direction in which the moving force acts; as the motion of a boat which a man draws to him with a rope. But if several powers, differently directed, act upon it at the same time, as it cannot obey them all, it will move in a direction somewhere between them. This is what is called the composition and resolution of motion, and is of the utmost importance in mechanics.

Suppose a body A, plate XXVI, fig. 3, to be acted upon by another body in the direction AB, while at the same time it is impelled by another in the direction AC, then it will move in the direction AD; and if the lines AB, AC, are made of lengths proportionate to the forces, and the lines CD, DB, drawn parallel to them, so as to complete the parallelogram ABDC, then the line which the body A will describe, will be the diagonal AD; and the length of this line will represent the force with which the body will move.

If we know the effect which the joint action of two powers has upon a body, and the force and direction of one of them, it is easy to find that of the other. For, suppose AD to be the direction and force with which the body moves, and AB to be one of the impelling forces, then, by completing the parallelogram, the other power AC is found.

Motion is said to be accelerated, if its velocity continually increases; to be uniformly accelerated, if its velocity increases equally in equal times.

Motion is said to be retarded, if its velocity continually decreases; and to be uniformly retarded, if its velocity decreases equally in equal times.

If you suppose a body to be put in motion by a single impulse, and moving uniformly, to receive a new impulse in the same direction, its velocity will be augmented, and it will go on with the augmented velocity.

If at each instant of its motion it receives a new impulse, the velocity will be continually increasing; and if this impulse is always equal, the velocity will be uniformly accelerated. The regularly increasing velocity with which a body falls to the earth, is an instance of accelerated motion, which is caused by the constant action of gravity.

To illustrate the doctrine of accelerated motion, let us suppose that, in the triangle ABC, fig. 4, AB expresses the time which a body takes to fall, and BC the velocity acquired at the end of the fall. Let AB be divided into a number of equal parts, indefinitely small, and from each of these divisions suppose lines, as DE, drawn parallel to BC; it is evident that those lines will express the velocities of the falling body in the several respective points of time, each being greater than the other, by a certain quantity of increase, which follows from the nature of the triangle. Now, the spaces described in the same time, are in proportion to the velocities; and the sum of the spaces described in all the small portions of time, is equal to the space described from the beginning of the fall. But the sum of all the lines parallel to BC, taken indefinitely near to each other, constitutes the area of the triangle. Therefore the space described by a falling body, in the time expressed by AB, with an uniformly accelerated velocity, of which the last degree is expressed by BC, will be represented by the area of the triangle ABC.

Let us now suppose that gravity ceased to act, and that the body moved during another portion of time, EF, equal to AB, with the acquired velocity represented by BC. As the space moved over is found by multiplying the velocity by the time, the rectangle CF will represent the space moved over in this second portion of time, which is twice the triangle ABC, and consequently twice the space it moved over with the accelerating velocity in the same time. But if we suppose gravity still to act, besides the space CF, which it would have moved over by its acquired velocity, we must add the triangle CGH, for the effect of the constant action of gravity; therefore, in this second portion of time, the body moves over three times the space as in the first. And as the velocities of falling bodies are in proportion to the spaces run over, it follows, that the velocities in each instant increase, as the numbers 1, 3, 5, 7, 9, &c.

It is found by experiment, that a body falling from a height, moves at the rate of $16\frac{1}{12}$ feet in the first second; and, as has been shewn above, acquires a velocity of twice that, or $32\frac{1}{6}$ feet in a second. At the end of the next second, it will have fallen $64\frac{1}{3}$ feet, the space being as the square of the time; the square of 2 is 4, and 4 times $16\frac{1}{12}$ is $63\frac{1}{3}$. By the same rule you may find, that in the third second it will fall 144 feet; in the next 256 feet, and so on. It is to be understood, however, that by this velocity is meant what bodies would acquire, if they were to fall through a space where there was no air; for its resistance considerably diminishes their velocity in falling. It has been already shewn, that if two forces act uniformly upon a body, they will cause it to move in a straight line; but if one of the forces is not uniform, but either accelerating or retarding, the moving body will describe a curve line.

The force with which a body moves, or which it would exert upon another body opposed to it, is always in proportion to its velocity multiplied by its weight, or quantity of matter. This force is called the momentum of the body: for if two equal bodies move with different velocities, it is evident that their forces, or momenta, are as their velocities; and if two bodies move with the same velocity, their momenta are as the quantities of matter; therefore, in all cases, their momenta must be as the products of their quantities of matter, and their velocities. This rule is the foundation of mechanics.

In consequence of the vis inertiæ of matter all motion produced by one force only acting upon a body, must be rectilinear; for it must receive some particular direction from the power that impressed it, and must retain that direction until it is changed by some other power. Whenever, therefore, we see a body moving in a curvilinear direction, we may be certain that it is acted upon by two forces at least. When one of the two forces ceases to act, the body will move again in a straight line. Thus a stone in a sling is moved round by the hand, while it is pulled towards the centre of the circle, which it describes, by the string: but when the string is let go, the stone flies off in a tangent to the circle.

Every body moved in a circle has a tendency to fly off from its centre, which endeavour of receding is called the centrifugal force: and it is opposed to the centripetal force; or that which, by drawing bodies towards the centre, makes them revolve in a curve. These two forces are called together central forces.

The centre of gravity of a body is that point about which all the parts of a body do in any situation exactly balance each other. Hence, if a body is suspended or supported by this point, the body will rest in any position in which it is put. Also, whatever supports that point bears the weight of the whole body; and while it is supported, the body cannot fall. We may therefore consider the whole weight of a body as centered in this point.

The common centre of gravity of two or more bodies is the point about which they would equiponderate, or rest, in any position.

If a line is drawn from the centre of gravity of a body, perpendicular to the horizon, it is called the line of direction; because it is the line that the centre of gravity would describe, if the body fell freely.

It is the property of this line, that while it falls within the base upon which the body stands, the body cannot fall; but if it fall without the base, the body will tumble. Thus the inclining body ABCD, fig. 5, whose cen-

tre of gravity is E, stands firmly on its base CDIK, because the line of direction EF falls within the base. But if a weight, as ABGH, is laid upon the top of the body, the centre of gravity of the whole body and weight together is raised to L; and then, as the line of direction LD falls without the base at D, the centre of gravity is not supported, and the whole body and weight will tumble down together.

The broader the base, and the nearer the line of direction is to the middle or centre of it, the more firmly does the body stand. On the contrary, the narrower the base, and the nearer the line of direction is to the side of it, the more easily may the body be overthrown, a less change of position being sufficient to remove the line of direction out of the base in the latter case than in the former.

From what has been said, it plainly appears, that if a plane CD on which a heavy body is placed, was elevated at C, the body would slide down upon the plane, whilst the line of direction falls within the base; but it would tumble or roll down when that line falls without the base. Thus the body A, fig. 6, would only slide down, whilst the body B would roll down upon it. If a body is suspended freely from different centres, its centre of gravity will be in the intersection formed by lines drawn from those centres perpendicular to the horizon. Hence we obtain an easy practical method of finding the centre of gravity of any irregular plane figure. Suspend it by any point, with the plane perpendicular to the horizon, and from the point of suspension hang a plumb-line, and draw a line upon the body where the string passes over; do the same for any other point of suspension, and where the two lines meet must be the centre of gravity; for the centre of gravity being in each line, it must be at the point where they intersect.

Motion, *spontaneous* or *muscular*, is that performed by the muscles at the command of the will.

Motion, *natural* or *involuntary*, that effected, without any such command, by the mere mechanism of the parts, such as the motion of the heart, pulse, &c.

Motion, *intestine*, the agitation of the particles of which a body consists.

Motion, in music, the manner of beating the measure, to hasten or slacken the time of the words or notes.

MOVEMENT, in mechanics, a machine that is moved by clock-work.

MOULD, or **Mold**, in the mechanic arts, &c. a cavity cut with a design to give its form or impression to some softer matter applied therein, of great use in sculpture, foundery, &c.

Moulds, in the manufacture of paper, are little frames composed of several brass or iron wires, fastened together by another wire still finer. Each mould is of the bigness of the sheet of paper to be made, and has a rim or ledge of wood to which the wires are fastened; these moulds are more usually called frames, or forms.

Moulds *for leaden bullets*, are little iron-pincers, each of whose branches terminates in an hemispherical concavity, which when shut, form an entire sphere: in the lips or sides where the branches meet, is a little jet or hole through which the melted lead is conveyed.

Moulds, *glaziers'*. The glaziers have two kinds of moulds, both serving to cast their lead. In the one they cast the lead into long rods or canes fit to be drawn through the vice, and the grooves formed therein; this they sometimes call ingot-mould. In the other they mould those little pieces of lead a line thick, and two lines broad, fastened to the iron-bars; these may be also cast in the vice.

Moulds, among plumbers, are the tables whereon they cast the sheets of lead. These they sometimes call simple tables; besides which they have other real moulds wherewith they cast pipes without soldering.

Moulds, used in basket-making are very simple, consisting ordinarily of a willow, or osier, turned or bent into an oval, circle, square, or other figure, according to the baskets, panniers, hampers, hats, and other utensils intended. On these moulds they make or more properly measure all their work, and accordingly they have them of all sizes, shapes, &c.

Moulds, among tallow-chandlers, are of two kinds; the first for the common dipped candles, being the vessel wherein the melted tallow is disposed, and the wick dipped; this is of wood, of a triangular form, and supported on one of its angles, so that it has an opening of near a foot at top; the other, used in the fabric of mould candles, is of brass, pewter, or tin; here each candle has its several moulds.

Mould, among gold-beaters, a certain number of leaves of vellum, or pieces of guts, cut square, of a certain size, and laid over one another, between which they put the leaves of gold and silver, which they beat on the marble with the hammer. They have four kinds of moulds, two whereof are of vellum, and two of gut: the smallest of those of vellum consists of forty or fifty leaves, the largest contains an hundred; for the others, each contains five hundred leaves. The moulds have all their several cases, consisting of two pieces of parchment, serving to keep the leaves of the mould in their place, and prevent their being disordered in beating.

Mould, in agriculture, a loose kind of earth, every where obvious on the surface of the ground, called also natural or mother-earth; by some also loam.

MOULDINESS, a term applied to bodies which corrupt in the air, from some hidden principle of humidity therein; and whose corruption shews itself by a certain white down, or lanugo, on their surface, which, viewed through a microscope, appears like a kind of meadow, out of which arise herbs and flowers, some only in the bud, others full blown, and others decayed, each having its root, stalk, and other parts.

MOULDING, any thing cast in a mould, or that seems to have been so, though in reality it were cut with a chisel, or the axe.

Mouldings, in architecture, projectures beyond the naked wall, column, wainscot, &c. the assemblage of which forms cornices door-cases, and other decorations of architecture.

MOUNTAINS. Elevations consisting chiefly of clay, sand, or gravel, are called hills. Those which consist chiefly of stone are called mountains. Mountains are divided into primeval, that is, of equal date with the formation of the globe, and secondary or alluvial. Among primeval, those of granite hold the first place. The highest mountains and

most extensive ridges throughout the globe are of that kind; as the Alps and Pyrenees in Europe; the Altuischan, Uralian, and Caucasus, in Asia; and the Andes, in America. The highest of them never contain metallic ores; but some of the lower contain ores of copper and tin. The granite next the ore always bounds in mica. Petrefactions are never found in these primeval mountains.

That the formation of these mountains preceded that of vegetables and animals, is justly inferred from their containing no organic remains, either in the form of petrefaction or impression. Naturalists are agreed, that granites were formed by chrystallization. This operation probably took place after the formation of the atmosphere, and the gradual excavation of the bed of the ocean, when the dry land appeared. For, by means of the separation of the aeriform fluids which constitute the atmosphere, the evaporation of part of the water into the atmosphere, and the gradual retreat of the remainder, the various species of earths, before dissolved or diffused through this mighty mass, were disposed to coalesce; and among these the siliceous must have been the first, as it is the least soluble; but as the siliceous earth has an affinity to the other earths with which it was mixed, some of these must have united in various proportions, and thus have formed, in distinct masses, the feltspar, schorl, and mica, which compose the granite. Calcareous earth enters very sparingly into the composition of this stone; but as it is found in schorl, which is frequently a component part of granite, it follows that it must be one of the primitive earths, and not entirely derived from marine exuviæ, as some have supposed. Quartz can never be supposed to be a product of fire; for in a very low heat it bursts, cracks, and loses its transparency, and in the highest degree of heat that we can produce, is infusible, so that in every essential point it is different from glass, to which some have compared it. As granite contains earths of every genus, we may conclude, that all the simple earths are original.

Mountains which consist of limestone or marbles of a granular or scaly texture, and not disposed in strata, seem also to have preceded the creation of animals, for no organic traces are found in them. Some of those which consist of argillaceous stones, and some of the siliceous, contain also no organic remains.

Alluvial mountains are evidently of posterior formation, as they contain petrefactions and other vestiges of organic substances, and these are always stratified. Mountains, as to structure, are entire, stratified, and confused. Entire mountains are formed of huge masses of stone, without any regular fissures, and are mostly homogeneous. The stratified mountains are those whose mass is regularly divided by joints or fissures: these are called horizontal, rising, or dipping. Homogeneous stratified mountains consist chiefly of stones of the argillaceous genus, or of the fissile compound species of the siliceous genus, as metallic rock; sometimes of lime-stone of a granular or scaly texture, in which no animal vestiges appear. This limestone reposes on the argillaceous or siliceous strata: sometimes the argillaceous are covered with masses of granite, sometimes of lava. These mountains, particularly those of gneiss, metallic rock, and horn-stone, are the chief seat of metallic ores Heterogeneous, or compound stratified mountains, consist of alternate strata of various species of stones, earth, sands, &c. The limestone here is always of the laminar, and not of the granular or scaly kind; and when it contains any ore, it is placed between its laminæ. Coal, bitumen, petrefactions, and organic impressions, are found in these mountains; also salts and calamine.

There are other mountains, which cannot properly be called stratified, as they consist only of three immense masses, the lowest granite, the middle argillaceous, and the upper limestone. Metallic ores are found in the argillaceous part, or between it and the limestone.

Confused mountains consist of stones heaped together without order, their interstices filled with clay, sand, and mica. They scarcely ever contain any ore. Besides these, there are many mountains in different parts of the world, which derive their origin from volcanoes; but of these it will be necessary to treat in a succeeding article. The height of mountains is usually calculated by means of the barometer. For this purpose two columns of mercury, or barometers, are provided, and one is kept at the foot of the mountain while the other is carried to its summit. The highest mountains are those which are situated at or near the equator; and the Andes are generally allowed to be the highest of these.

The line of congelation, or of perpetual frost, on mountains, is calculated at 15,400 feet, at or near the equator; at the entrance of the temperate zone, at 13,428; on Teneriff, at 1000; in Auvergne (lat. 45) 6,740; with us (lat. 52) 5,740. On the Andes, vegetation ceases at 14,697 feet; and on the Alps, at 9,585. The air is so dry in these elevated situations, that M. d'Arcet observed, that on the Pic de Midi, one of the Pyrenees, salt of tartar remained dry for an hour and a half, though it immediately moistened in the same temperature at the bottom of the mountain.

MOUNTING, in military affairs, signifies going upon duty. Thus, mounting a breach, is running up to it; mounting the guard, is going upon guard; and mounting the trenches, is going upon duty in the trenches; but mounting a cannon, mortar, &c. is the setting it on its carriage, or the raising its mouth.

MOUSE. See Mus.

MOUTH. See ANATOMY.

MUCILAGE, a glutinous matter obtained from vegetables, transparent and tasteless, soluble in water, but not in spirit of wine. It chiefly consists of carbon, hydrogen, and a small quantity of oxygen.

MUCUS, a fluid secreted by certain glands, and serving to lubricate many of the internal cavities of the body. In its natural state it is generally limpid and colourless; but from certain causes, will often assume a thick consistence and whitish colour like pus. Strong sulphuric acid and water, diluted sulphuric acid, and caustic alkaline lixivium and water, will serve to distinguish pus from mucus; the vitriolic acid separates it from coagulable lymph and alkaline lixivium from serum. Hence, when a person has any expectorated matter, the decomposition of which he wishes

to ascertain, let him dissolve it in vitriolic acid, and in caustic alkaline lixivium; and let him add pure water to both solutions. If there is a fair precipitation in each, he may be assured that some pus is present. But if there is a precipitation in neither, it is a certain test that the mixture is entirely mucus. If the matter cannot be made to dissolve in alkaline lixivium by time and trituration, we have also reason to believe that it is pus.

MUCUS, *nasal:* this name is given to a liquid which is secreted in the cavities of the nose and is discharged outwardly; either by the nostrils in the form of drops, or in that of masses more or less thick; or by the fauces when it descends by the posterior part of the nasal cavities, in which it is thrown out by spitting. The nasal mucus is at first liquid, clear and limpid, a little viscid and adhesive, without smell, of a saline and acrid taste. This liquid, being always exposed to the air which continually passes through the nostrils is constantly thicker, more viscid, and more adhesive, than the tears, and the carbonate of soda which it contains, whilst the latter contains only soda, announces that the air deposits in it a part of the carbonic acid which it contains, especially as it is expired out of the lungs. When it becomes thick in the air, frequently assumes in it the form of small, dry, brilliant, and, as it were, micaceous plates. The nasal mucus experiences no real petrifaction in the air. Water does not dissolve it. Acids thicken it when they are concentrated and employed in small proportions; but when we add a larger quantity, they redissolve, and give it different shades of colour. The mucus of the nostrils maintains the softness of the membranaceous sides of the nasal cavities. It moderates the too great sensibility of the nervous papillæ; stops and fixes the odorous bodies, and blunts their too great activity. It likewise purifies the air that is respired, by taking from it the pulverulent particles which it carries along with it, and which would be more hurtful in the lungs.

MUFFLE. A small earthen oven, made and sold by the crucible manufacturers. It is to be fixed in a furnace, and is useful for cupellation, and other processes which demand access of air.

MUFTI, or **Muphti**, the chief of the ecclesiastical order, or primate, of the musselman religion. The authority of the mufti is very great in the Ottoman empire; for even the sultan himself, if he would preserve any appearance of religion, cannot, without hearing his opinion, put any person to death, or so much as inflict any corporal punishment. In all actions, especially criminal ones, his opinion is required by giving him a writing, in which the case is stated under feigned names, which he subscribes with the words, *He shall*, or *shall not, be punished.* Such outward honour is paid to the mufti, that the grand seignior himself rises up to him, and advances seven steps to meet him, when he comes into his presence. The election of the mufti is solely in the grand seignior, who presents him with a vest of rich sables, &c.

MUGIL, *mullet*, a genus of fishes of the order abdominales. The generic character is, lips membranaceous; the inferior carinated within: teeth none; at the corners of the mouth an inflicted callus: gill membrane with six curved rays: body fleshy; scales large; dorsal fins two.

Gmelin notices only five species. Shaw mentions nine. *M. cephlaus*, or the common mullet is generally about 14 inches in length, and is found not only in the Northern and Mediterranean Seas, but in the Indian and Western Oceans. The mullets collect in multitudes almost close to the shores, thrusting their heads into the soft muddy bottoms in quest of aquatic insects. On the approach of summer, they ascend rivers, to a considerable distance from the sea, in order to deposit their ova. They are regarded by many as excellent food, but are not often seen at the tables of the opulent.

MULBERRY. See Morus.

MULE, in zoology, a mongrel kind of quadruped, usually generated between an ass and a mare, and sometimes between a horse and a she-ass. The mule is a sort of a monster, of a middle nature between its parents, and therefore incapable of propagating its species; so careful is nature to avoid filling the world with monsters. Mules are chiefly used in countries where there are rocky and stony roads, as about the Alps, Pyrenees, &c. See Equus.

MULES, among gardeners, denote a sort of vegetable monsters produced by putting the farina fecundans of one species of plant into the pistil or utricle of another. The carnation and sweet-william being somewhat alike in their parts, particularly their flowers, the farina of the one will impregnate the other, and the seed so enlivened will produce a plant differing from either.

MULLER, or **Mullar**, a stone flat and even at the bottom, but round at top, used for grinding of matters on a marble.

MULLERIA, a genus of the class and order diadelphia decandria. Pericarp elongated, fleshy, necklace-form, with one-seeded globules. There is one species, a tree of Surinam.

MULLET, or **Mollet**, in heraldry, a bearing in form of a flat, or rather of the rowel of a spur, which it originally represented.

MULLUS, *surmullet*, a genus of fishes of the order thoracici. Gen. char. head compressed, scaly; mouth bearded; gill-membrane three-rayed; body covered with subdeciduous scales.

Gmelin reckons six, Shaw thirteen species. 1. *Mullus ruber*, the red surmullet, is principally found in the Mediterranean and north seas, where it arrives at the length of twelve or fifteen inches; its colour is a rose-red, tinged with olive-colour on the back, and of a silvery cast towards the abdomen. It is generally considered as a very delicate fish, and is celebrated for having been the fashionable object of Roman luxury, and for which enormous sums are reported to have been sometimes given. The Romans practised a singular refinement in luxury, by first bringing the fish alive to the table in a transparent vessel, in order that the guest might contemplate the beautiful, and rapid changes of its evanescent colours during the time of its gradual expiration; after which it was prepared for their repast.

MULTILATERAL, in geometry, is applied to those figures which have more than four sides or angles, more usually called polygons.

MULTINOMIAL, or **Multinomial roots**, in mathematics, such roots as are composed of many names, parts, or members; as, $a + b + d + c$, &c. See Root.

MULTIPLE, in arithmetic, a number which comprehends some other several times, thus 6 is a multiple of 2.

Multiple ratio, or **proportion**, is that which is between multiples. If the less term of the ratio is an aliquot part of the greater, the ratio of the greater to the less is called multiple, and that of the less to the greater submultiple. A submultiple number is that contained in the multiple; thus the numbers 1, 2, and 3, are submultiples of 9. Duple, triple, &c. ratios, as also subduples, subtriples, &c. are so many species of multiple and submultiple ratios.

MULTIPLYING-GLASS, in optics, one wherein objects appear increased in number. It is otherwise called a polyhedron, being ground into several planes, that make angles with each other; through which the rays of light issuing from the same point undergo different refractions, so as to enter the eye from every surface in a different direction.

MUM, a kind of malt liquor, much drunk in Germany, and chiefly brought from Brunswick, which is the place of most note for making it.

MUMMY. See Embalming.

MUNICIPAL, in the Roman civil laws, an epithet which signifies invested with the rights and privileges of citizens.

Municipal, among us, is applied to the laws that obtain in any particular city or province; and those are called municipal officers who are elected to defend the interests of cities, to maintain their rights and privileges, and to preserve order among the Roman citizens.

MURÆNA, the *eel*, a genus of fishes of the order apodes. Gen. char. head smooth; nostrils tubular; gill membrane ten-rayed; eyes covered by the common skin; body round, smooth; and mucous spiracle behind the head or pectoral fins. There are five species according to Shaw. Gmelin enumerates nine. *M. anguilla*, or the common eel, is particularly distinguished by the steadiness and uniformity of its colours; an olive brown on the back, and silvery lustre on the sides and beneath; but more expressively still by the great elongation of its under jaw. Its general size is from two to three feet; it is slow in its growth, and considered as very long-lived. Its usual food consists of insects, worms, and the eggs of other fishes. It is viviparous, producing great numbers at a birth; but of a very diminutive size. It continues generally during the day in its hole in the banks, which it furnishes with two avenues to facilitate its escape and security. By night it ranges for food. In winter it appears to be ingulphed in mud, and remains in this state of seclusion and tranquillity, if not torpor, till the return of spring invites it to a renewal of its excursions.

M. conger, or the conger eel, is generally darker above, and more splendid beneath than the former species. It grows to its largest size in the Mediterranean, where it is sometimes found ten feet long, and of the weight of a hundred pounds. It is found in the North and American seas also: It occasionally, particularly in the spring, makes excursions into rivers, and is found in vast abundance in the Severn. Congers are extremely voracious, devouring immense quantities of the smaller fishes, and of crabs before the shell of the latter is completely formed and hardened.

MURDER, or **Murther**. See Homicide.

MUREX, in natural history a genus of univalve or simple shells, without any hinge, formed of a single piece, and beset with tubercles or spines. The mouth is large and oblong, and has an expanded lip, and the clavicle is rough. The clavicle of the murex is in some species elevated, in others depressed; and the mouth is sometimes dentated, and at others smooth; the lip also in some is digitated, in others elated, and in some laciniated; and the columella is in some smooth, in others rugose.

Murex, in zoology, a genus of insects belonging to the order of vermes testacea. This animal is of the snail kind: the shell consists of one spiral valve, rough, with membranaceous furrows; and the aperture terminates in an entire canal, either straight or somewhat ascending. From a species of murex on the coasts of Guayaquil and Guatimala in Peru, a liquor is extracted, which dyes cottons, silks, and wool of a beautiful permanent colour. The shell which contains it adheres to the rocks that are washed by the sea. It is of the size of a large walnut.

MURIATES, in chemistry, a genus of salts formed from the muriatic acid with certain bases. When heated they melt, and are volatilized, without undergoing decomposition: they are soluble in water; effervesce with sulphuric acid, and white acrid fumes of muriatic acid are disengaged; when mixed with nitric acid they exhale the odour of oxymuriatic acid.

MURIATIC ACID, the **Hydrochloric** of the French chemists. Let 6 parts of pure and well dried sea salt be put into a glass retort, to the beak of which is luted, in a horizontal direction, a long glass tube artificially refrigerated, and containing a quantity of ignited muriate of lime. Upon the salt pour at intervals 5 parts of concentrated oil of vitriol, through a syphon funnel, fixed air-tight, in the tubulure of the retort. The free end of the long tube being recurved, so as to dip into the mercury of a pneumatic trough, a gas will issue, which on coming in contact with the air, will form a visible cloud, or haze, presenting, when viewed in a vivid light, prismatic colours. This gas is muriatic acid. When received in glass jars over dry mercury, it is invisible, and possesses all the mechanical properties of air. Its odour is pungent and peculiar. Its taste acid and corrosive. Its specific gravity, according to Sir H. Davy, is such, that 100 cubic inches weigh 39 grains, while by estimation, he says, they ought to be 38.4 gr. By the latter numbers the specific gravity, compared to air, becomes 1.2590. By the former number the density comes out 1.2800

If an inflamed taper be immersed in it, it is instantly extinguished. It is destructive of animal life; but the irritation produced by it on the epiglottis scarcely permits its descent into the lungs. It is merely changed

in bulk by alterations of temperature; it experiences no change of state. When potassium, tin, or zinc, is heated in contact with this gas over mercury, one-half of the volume disappears, and the remainder is pure hydrogen. On examining the solid residue, it is found to be a metallic chloride. Hence muriatic acid gas consists of chlorine and hydrogen, united in equal volumes.

The marine acid in commerce has a straw colour; but this is owing to accidental impurity; for it does not obtain in the acid produced by the impregnation of water with the aeriform acid. The muriatic acid is one of those longest known, and some of its compounds are among those salts with which we are most familiar.

MURRAIN, or GARGLE, a contagious disease among cattle, principally caused by a hot dry season, or rather by a general putrefaction of the air, which begets an inflammation of the blood, and a swelling in the throat, that soon proves mortal, and is communicated from one to another, though it generally goes no farther than to those of the same kind. The symptoms of this disease are a hanging down and swelling of the head, abundance of gum in the eyes, a rattling in the throat, a short breath, palpitation of the heart, staggering, a hot breath, and a shining tongue.

MUS, the *rat*, a genus of mammalia of the order glires. Gen. char. fore-teeth, upper, wedge-formed; three grinders almost always each side each jaw; clavicles in the skeletons. There are forty-six species, of which the following are the most remarkable.

M. zibethicus, or the musk rat, is as large as a small rabbit, and very common in Canada; and resembles the beaver in the shape of its body, and in its instincts and character. It lives in society, and constructs its habitation with great skill and art, about two feet in diameter, and stuccoed within with particular neatness, on the border of some lake or stream. On the outside it is covered with a matting of rushes, compacted with great closeness, to preclude moisture. These animals live on roots and herbage, which, however, they do not store up in their houses, but make excursions for as they are demanded during the winter; in summer they make long progresses in pairs. They have attached to them a strong odour of musk; and walk and run with great awkwardness; are easily tamed, and highly valued for their fur.

M. decumanus, or the Norway rat, is imagined to have been imported into Europe from India, and in this country has almost extirpated the black rats, which formerly abounded in it. It subsists not only on grain and fruits, but frequently attacks poultry and rabbits, as well as various other animals. It is about nine inches long in the body, and nine more in the tail; will swim with considerable ease; is in the highest degree prolific, producing occasionally even eighteen young at a time, and breeding not unfrequently three times a year.

M. rattus, or the black rat, is considerably smaller than the former, and in this country has been nearly annihilated by it. Its habits are almost precisely similar to those of the former. It is supposed to come from the same countries; but is thought to be a native of North America also. It is reported by travellers, that in various parts of Germany it is sometimes taken and domesticated, and, having a bell put round its neck, is thus almost invariably found to alarm all others of its species from the vicinity.

M. amphibius, or the water rat, inhabits both the temperate and cold climates of Europe and Asia, frequenting the banks of rivers, in which it burrows. It subsists on frogs, and roots, and other vegetable substances; swims with great speed, and can remain under water a considerable time. It is never known to infest houses.

M. lemmus, or the leming These animals are sometimes five inches long in the body, and in some countries, (as Siberia), only three. They abound in the mountainous districts of Norway and Lapland. In their general habits they are not particular, residing in a dispersed manner. On certain occasions, however, they descend into the plains in innumerable and formidable multitudes.

M. œconomus, or the œconomic rat, resembles the leming in the circumstance of irregular migrations. These are met with particularly in Siberia, burrowing with the greatest skill, and forming considerable magazines of provisions. They are about five inches and a quarter in their whole length. In their migrations they swim over rapid rivers, preserving a course directly to the west, and experiencing extreme fatigue and peril, to which immense numbers of them become victims. A single party has been so numerous as to take two hours in passing before the astonished spectator. Scarcity of food is supposed the grand impulse to these progresses. The inhabitants of Kamtschatka rob the hoards of these animals in winter.

M. cricetus, or the hamster, is a species of the pouched rats, and the sole European species of that description. The pouches are one on each side of the mouth, and when filled, are like two blown bladders. These animals are found in Poland and Russia, and are extremely injurious by the quantities of grain which they devour, and carry off for their autumnal store in their pouches. The structure of their habitations is very curious. The females arrange their mansions differently from the males, and never reside with them. As winter approaches, they seclude themselves completely, and enjoy their stores, which are generally consumed when winter reigns in full rigour, about which time they roll themselves up and continue till spring in a state of profound slumber, or torpor. Their bodies are cold, the fat coagulated, and their limbs stiffened, and they may be opened without awaking them. The heart beats only fifteen times in a minute, while in the summer its pulsations are 150 in the same time. The waking of the hamsters from their lengthened sleep is very gradual, occupying sometimes no less than two hours. These animals are unsocial, fierce, and malignant. They attack every weaker creature, and very frequently destroy each other.

M. musculus, or the common mouse, inhabits almost every part of the world, is shy and timid, but not ferocious. It produces generally from six to ten at a birth, and breeds several times in a year. Its skin is sleek, and its eyes

are bright and lively; its limbs are neatly formed, and its movements are extremely agile. It is occasionally seen of perfect whiteness. It haunts the habitations of man, from which it is scarcely ever found at any considerable distance, and in which it commits no trifling depredations.

M. sylvaticus, or the long-tailed field-mouse, is somewhat larger than the former, and of a yellowish brown colour. It feeds on acorns, fruits, and grain, and lays up magazines in its burrow for the winter. It is found principally in dry grounds: is common in all the temperate regions of Europe, and is particularly abundant and destructive in France, where it is stated to commit very great waste. Under a scarcity of the usual supplies, these animals are supposed to destroy each other.

M. messorius, or the harvest mouse, is the smallest of British quadrupeds, weighing only the sixth part of an ounce. Its nest is most artificially platted of the blades of wheat, and is of the size of a cricket ball, the opening to it being closed up so skilfully, as to be almost imperceptible. Such is its compactness, that it may be rolled over the table without derangement. One found of this description contained eight young, and appeared completely full without the dam. In the winter these animals burrow deep in the earth, but their favourite habitation is the corn-stack.

M. socialis, social mouse. The social mouse is a native of the Caspian deserts between the Volga and the Yaik, and the country of Hiscania. It lives in low sandy situations, in large societies; the ground in many places being covered with the little hillocks formed by the earth cast out in forming the burrows, which are about a span deep, with eight or more passages. The animals are always observed to live in pairs, or with a family; they are fond of tulip roots, which form a principal article of their food.

M. typhlus, blind rat. This is perhaps one of the largest and most remarkable of its tribe, measuring between seven and eight inches in length, and being entirely destitute both of eyes and tail,

MUSA, the *plantain tree*, a genus of the monœcia order, in the polyandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. There are three species.

1. *Musa paradisiaca*, is cultivated in all the islands of the West Indies, where the fruit serves the Indians for bread; and some of the white people also prefer it to most other things, especially to the yams and cassada bread. The plant rises with a soft stalk 15 or 20 feet high; the lower part of the stalk is often as large as a man's thigh, diminishing gradually to the top, where the leaves come out on every side: these are often eight feet long, and from two to three broad, with a strong fleshy mid-rib, and a great number of transverse veins running from the mid-rib to the borders. This tree is cultivated on a very extensive scale in Jamaica, without the fruit of which, the island would not be habitable, as no species of provision could supply their place.

2. *Musa sapientum*, the banana tree. This species differs from the preceding in having its stalks marked with dark purple stripes and spots. The fruit is shorter, straighter, and rounder; the pulp is softer, and of a more luscious taste. It is never eaten green; but when ripe it is very agreeable, either eaten raw or fried in slices as fritters; and is relished by all ranks of people in the West Indies. Both these plants were carried to the West.

2. *Musa troglodytarum*, has a scarlet spathe and scarlet berry, but not eatable.

MUSCA, in natural history, the *fly*, a genus of insects of the order diptera: mouth with a soft exserted fleshy proboscis, and two equal lips; sucker furnished with bristles; feelers two, very short; antennæ generally short. This is a very numerous genus, not fewer than a thousand species have been enumerated. They are divided into sections; *viz.* A. with short feelers; and B. without feelers. These sections are again separated into others. The larva in the different tribes of flies differs far more in habit than the complete insects, some being terrestrial, and others aquatic. Those of the common kinds are emphatically distinguished by the title of maggots, and spring from eggs deposited on various putrid substances. Several of the aquatic kinds are of singularly curious formation, and exhibit wonderful examples of the provision ordained by nature for the preservation of even the meanest of animals. The general form of the pupa is that of an oval, differently modified, according to the species, and formed by the external skin of the larva. Some species cast their skin before their change into the pupa state. One of the most remarkable species is *M. chamæleon*, which is a large black fly, with a broad, flattish abdomen, having the sides of each segment yellow, forming so many abrupt semi-bands across that part. It proceeds from an aquatic larva, two inches and a half in length, which is common in stagnant waters in the summer months, and passes into its chrysalis state without casting its skin, which dries over it. *M. tenax* is a remarkable insect, about the size of a drone, of a brown colour, with transparent wings. It proceeds from a larva of a very singular appearance, being a long-tailed brown maggot, about three quarters of an inch in length, which is seen in muddy stagnant waters, drains, and other places of the dirtiest description. The feet are wonderfully calculated for enabling the animal to climb perpendicular places, in order to seek some proper situation to undergo its change into chrysalis, being very broad, and beset on their under surface with numerous small hooked claws. The larva commonly changes to a pupa about the end of August, the skin contracting and drying round the body. After remaining in this state about a fortnight, it gives birth to the complete insect. It is common in the month of September, and is often mistaken for a drone. Among the bristly flies is the *M. canaria*, or common blow-fly, which deposits its eggs on animal flesh, either fresh or putrid. The larva, or maggots, hatch in the space of a few hours. When full grown, which happens in eight or ten days, they are of a yellowish colour, with a slight tinge of pale red. When the animal changes to a pupa, the skin dries round it, and the whole assumes a completely oval form, and a reddish colour. In ten days after the fly emerges.

M. vivipara greatly resembles the preceding, and is found in similar situations, but is viviparous, disclosing small ready-formed larvæ instead of eggs, which in this species are hatched internally.

MUSCI, in botany, *mosses*, one of the seven families, into which Linnæus divided all vegetables. The characteristics of mosses are, anthers without filaments; male flower constituted by the presence of the anthers, placed apart from the female, either on the same or distinct roots; female flower deprived of the pistillum; the seeds devoid of both lobes, and proper coverings. These plants constitute the second order of the class cryptogamia. This order is subdivided into eleven genera, from the presence or absence of the calyx, which in these plants is a veil that is placed over the tops of the stamina, and denominated calyptra, from the sexes of the plants, which bear male and female flowers, sometimes on the same, sometimes on distinct roots, and from the manner of growth of the female flowers, which are sometimes produced singly, sometimes in bunches or cones.

Musci, is also the name of the fifty-sixth order in Linnæus's Fragments of a Natural Method, consisting of genera, which are exactly those of the second order in the class cryptogamia. These plants resemble the pines and firs, and other evergreens in that class, in the form and disposition of their leaves, and manner and growth of the female flowers, which are generally formed into a cone. They frequently creep and extend themselves like a carpet upon the ground, trees and stones, collected into bunches or tufts. Few of the mosses are annual plants; being mostly perennial and evergreens. Their growth is slow; though preserved dry several years, they resume their original verdure upon being moistened. They delight in a cool moist situation, and northerly exposure, where they are screened from the sun. The roots are fibrous, slender, branched, and short. The stems and branches are cylindric, and weak, creeping on the ground, and striking root on every side.

MUSCICAPA, or FLY-CATCHER, a genus of birds belonging to the order of passeres. The bill is flatted at the base, almost triangular, notched at the upper mandible, and beset with bristles; the toes, generally, divided as far as their origin. There are 97 species; the most remarkable are:

1. The *grisola*, or spotted fly-catcher, about five inches and three quarters long. The head is large, of a brownish hue, spotted obscurely with black: the back is of a mouse-colour; the wings and tail are dusky; the breast and belly white. It is a bird of passage; appears here in the spring, breeds with us, and departs in September. It lays four or five pale eggs marked with red. It feeds on insects, and collects them on the wing.

2. The *flabellifera*, or fan-tailed fly-catcher, is in length six inches and a half: the head is black, which colour descends on the back part lower than the nape, whence it passes forward in a narrow collar to the throat; the chin, throat, and sides of the neck are white. This species inhabits the southern isles of New Zealand; where it is seen constantly hunting after insects, and flies always with its tail in shape of a fan.

3. The *caribonensis*, or cat-bird, is somewhat larger than a lark; length eight inches; bill black; the upper parts of the body and wings are of a deep brown; the under ash-coloured; the crown of the head is black; the tail is blackish; and the legs are brown. This species is found in Virginia.

4. The *rubicolius*, purple-throated fly-catcher, is about the size of a blackbird; the whole plumage is black, except the chin, throat, and fore part of the neck, on which is a large bed of beautiful crimson, inclining to purple; the legs are black. These birds inhabit Cayenne and other parts of South America. They feed on fruits and insects; and are lively birds, always in action.

MUSCLE, See ANATOMY.

MUSCLES, *Insertion and force of the*. Plate XXVI figs. 3 and 9. The all-wise Author of nature has furnished animals with limbs, moveable about the joints by means of muscular cords, inserted near the joint or centre of motion. In order to calculate the force of any muscle, we are to consider the bones as levers; and then the power or force of the muscle will be always to the resistance or weight it is capable of raising, as the greater distance of the weight from the centre of motion is to the lesser distance of the power. Hence, it being found by experiments, that a robust young man is able to suspend a weight R, equal to twenty-eight pounds, when the arm is extended in a supine and horizontal situation, we have this proportion, viz. the force of the muscle I D is to the weight R, = 28 lb, as the distance D C is to the distance I C. But it is found, that D C, the length of the cubit and hand, is more than twenty times greater than I C, the distance of the muscle from the centre of motion. Therefore the force of the muscle I D. must be more than twenty times greater than the weight R, or more than 28 × 20 = 560 lb.

Again, to find the force which the biceps and brachiæus muscles exert, when the humerus D A is perpendicular to the horizon, we are first to consider what weight a man is capable of sustaining in this posture, viz. R = 35 pounds, and next the quantity of the distances C B, C I, which in this case are as 16 to 1. Therefore the force of these muscles is to the weight R = 35 pounds, as the distance C B = 16 is to the distance I C = 1; or the force is equal to 560, as before.

But what appears most wonderful is, the force of the muscles that move the lower jaw; which, when taken altogether, do not in a man exceed the weight of 1 pound, and yet exert a force equal to 534 pounds, and in mastiff-dogs, wolves, bears, lions, &c. their force is vastly superior, so as to break large bones, as they practise daily in their feeding.

MUSES, certain fabulous divinities amongst the Pagans, supposed to preside over the arts and sciences: for this reason it is usual for the poets, at the beginning of a poem, to invoke these goddesses to their aid. Some reckon the muses to be no more than three, viz. Mneme, Aœde, and Melete; that is, memory, singing, and meditation: but the most ancient authors, and particularly Homer and Hesiod, reckon nine, viz. Clio, which means glory; Euterpe, pleasing; Thalia, flourishing; Melpomene, attracting; Terpsichore, rejoicing the heart;

Erato, the amiable; Polyhymnia, a multitude of songs; Urania, the heavenly; and Calliope, sweetness of voice. To Clio, they attributed the invention of history; to Melpomene, tragedy; to Thalia, comedy; to Enterpe, the use of the flute; to Terpsichore, the harp; and to Erato, the lyre and lute; to Calliope, heroic verse; to Urania, astrology; and to Polyhymnia, rhetoric.

MUSEUM, a collection of rare and interesting objects, selected from the whole circle of natural history and the arts, and deposited in apartments or buildings, either by the commendable generosity of rich individuals, general governments, or monarchs, for the inspection of the learned and the great mass of the public. The term which means, literally, a study, or place of retirement, is said to have been applied originally to that part of the Royal Palace at Alexandria appropriated for the use of learned men, and the reception of the literary works then extant. According to ancient writers, they were formed into classes or colleges, each of which had a competent sum assigned for their support; and we are further informed, that the establishment was founded by Ptolemy Philadelphus, who added a most extensive library.

MUSHROOM. See AGARICUS.

MUSIC, a science which teaches the properties, dependencies, and relations of melodious sounds; or the art of producing harmony and melody by the due combination and arrangement of those sounds.

The ancient writers on this science differ greatly as to its object and extent. In general, they give to it a much wider latitude than that which it obtains with us. Under the name of music they comprehended not only the melodious union of voices and instruments, but also the dance, gesture, poetry, and even all the other sciences. Hermes defines music to be the general knowledge of order; which was also the doctrine of Plato, who taught that every thing in the universe was music.

Music, however, properly so called, only concerns the due order and proportion of sounds; and is divided into two parts, the theoretical and the practical. Theoretical music comprehends the knowledge of harmony and modulation; and the laws of that successive arrangement of sound by which air, or melody, is produced. Practical music is the art of bringing this knowledge and those laws into operation, by actually disposing of the sounds, both in combination and succession, so as to produce the desired effect; and this is the art of composition: but practical music may, in fact, be said to extend still further, and to include not only the production of melodious and harmonious composition, but also its performance; and to such a facility in execution, and nicety of expression, has this department of practical music arrived at the present day, that its professors, generally speaking, hold a truly respectable rank in the various list of modern artists; and are highly, as well as most deservedly esteemed by all lovers and patrons of musical taste and ingenuity.

MUSSÆNDA, a genus of the pentandria monogynia class and order. The cor. is funnel-form; stigma 2, thickish; berry oblong, inferior; seeds disposed in four rows. There are three species, shrubs of China.

MUSK. This substance is secreted into a bag, situated in the umbilical region of the quadruped called moschus moschifer. Its colour is brownish red; its feel unctuous; its taste bitter; and its smell aromatic and intensely strong. It is partially soluble in water, which acquires its smell: and in alcohol, but that liquid does not retain the odour of musk.

MUSKET, a fire-arm borne on the shoulder, and used in war. The length of a musket is fixed at 3 feet 8 inches from the muzzle to the pan, and it carries a ball of 29 to 2 pounds.

In fortification, the length of the line of defence is limited by the ordinary distance of a musket-shot, which is about 120 fathoms.

MUSKETOON, a kind of short thick musket, the bore of which is the thirty-eighth part of its length: it carries five ounces of iron, or seven and a half of lead, with an equal quantity of powder. This is the shortest sort of blunderbus.

MUSLIN, a fine thin sort of cotton cloth, which bears a downy nap on its surface. There are several sorts of muslins brought from the East Indies, and more particularly from Bengal.

MUST, the juice of grape, composed of water, sugar, jelly, gluten, and bitartrate of potash. From a French wine pipe of *must*, the Marquis de Bullion extracted half an ounce of sugar, and 1-16th of an ounce of tartar. Proust says, the muscadine grape contains about 30 per cent. of a peculiar species of sugar. By fermentation, it forms wine.

MUSTELA, the *otter*, a genus of quadrupeds of the order feræ: the generic character is, foreteeth upper six, erect, acuter, distinct; lower; six, obtuser, crowded, placed within; tongue smooth.

M. lutra, common otter. The common otter is found in almost every part of Europe, as well as in the colder regions of Asia; inhabiting the banks of rivers, and feeding principally on fish. The length of the otter is nearly two feet from nose to tail, and of the tail about 16 inches. Its colour is a deep brown, with a small light-coloured patch on each side the nose, and another under the chin. The otter shews great sagacity in forming its habitation: it burrows under ground on the banks of some river or lake, and always makes the entrance of its hole under water, working upwards to the surface of the earth: and before it reaches the top, makes several holts or lodges, that in case of high floods it may have a retreat, for no animal affects lying drier; and then makes a minute orifice for the admission of air. The otter is naturally a very fierce animal; and when hunted with dogs, as is sometimes the practice, will inflict very severe wounds on its antagonists. The female produces four or five young at a birth; this commonly happens early in the spring. The young otters, if taken at a very early age, may be successfully tamed, and taught by degrees to hunt for fish, and bring them to their master.

2. *M. lutreola*. the smaller otter, very much resembles the common otter, but is smaller; the body is of a dusky colour, but with a considerable cast of tawny. In size it falls short of the common otter, measuring about a foot in length. Its fur is very valuable, and next in beauty to that of the sable.

3. *M. lutris*, the sea otter, is the largest of

the otters, measuring about 3 feet from the nose to the tail, and the tail 13 inches. The colour of this species is a deep, glossy, brownish black, the fur being extremely soft and very fine; on the forehead is generally a cast of greyish or silver colour. According to Mr. Pennant, it is one of the most local animals we are acquainted with, being entirely confined between lat. 44 and 60 north; and between east long. from London. 126. to 150.; inhabiting, in great abundance, Bering's islands, Kamtschatka, the Aleutian and Fox islands, between Asia and America.

4. *M. fero*, ferret, has eyes red and fiery. It inhabits Africa. In Europe it is tamed to catch rabbits, rats, &c. It procreates twice a year, and brings forth from six to eight at a time.

M. erminea, stoat: inhabits Europe, the cold parts of Africa, Asia, and China. Body about ten inches long; hair short, which in northern climates becomes white, except the outer half of the tail, which remains black. The fur is very valuable.

MUSTER, in a military sense, a review of troops under arms, to see if they be complete, and in good order; to take an account of their numbers, the condition they are in, viewing their arms and accoutrements, &c.

MUSTER *roll*, a specific list of the officers and men in every regiment, troop, or company, which is delivered to the inspecting field-officer, muster-master, regimental or district pay-master (as the case may be) whereby they are paid, and their condition is known.

MUTE. If any person being arraigned on any indictment or appeal for felony, &c. shall upon such arraignment stand mute, or will not answer directly to the felony, he shall be convicted of the offence, and the court shall thereupon award judgment and execution, in the same manner as if he had been convicted by verdict or confession.

MUTILLA, a genus of insects, of the order hymenoptera; the generic character is, antennæ filiform; feelers four; the articulations obconic, seated on the tip of the lip; jaw membranaceous at the tip, lip projecting obconic; wings in most species obconic; body pubescent, thorax retuse behind; sting pungent, concealed. The *M. helvola* inhabits the Cape of Good Hope.

MUTINY, in a military sense, to rise against authority. Any officer or soldier who shall presume to use traitorous or disrespectful words against the king, or who shall behave himself with contempt or disrespect towards the general, or other commander-in-chief of the forces, or shall speak words tending to their hurt or dishonour, is guilty of mutiny; or, who shall begin, excite, cause, or join in, any mutiny or sedition; or, who, being present at any mutiny or sedition, does not use his utmost endeavours to suppress the same, or coming to the knowledge of any mutiny, or intended mutiny, does not, without delay, give information to his commanding officer, is guilty of mutiny.

MUTULE. See ARCHITECTURE.

MYA, the *gaper*, in zoology; a genus belonging to the order of vermes testacea, the characters of which are these. It has a bivalve shell gaping at one end; the hinge, for the most part, furnished with a thick, strong, and broad tooth, not inserted into the opposite valve. This animal is an ascidia. There are about twenty-five species. *M. declivis* has a brittle, semi-transparent shell, sloping downwards near the open end; the hinge slightly prominent. It is found about the Hebrides, where the fish is in great esteem. *M. margaritifera*, is found in mountainous rivers, and about cataracts. It is about five inches long, and half as many broad; and it is noted for producing mother of pearl and pearls; the latter is said to be a disease of the fish, analogous to the stone in the human body.

MYCTERIA, the JABIRU, a genus of birds belonging to the order of grallæ. The bill is long, bending upwards, and acute; the nostrils are small and linear; there is no tongue; and the feet have four toes. There are two species.

M. Americana, or the American jabiru, is nearly six feet in length. It abounds in the levels of Cayenne, and other parts of South America, feeds upon fish, of which it devours immense quantities, and builds in vast trees, laying only two eggs. It is extremely wild; and when young, is used for food.

M. Asiatica is likewise a very large bird, inhabits the East Indies, and feeds on snails.

MYOPES. Those who by a natural defect have the cornea and crystalline humour too convex, are called myopes. This figure, which increases the quantity of refraction, tends to render the rays of such pencils as are formed in the eye more convergent, so that the point where these same rays meet is on this side of the retina. Myopes see distinctly those objects only which are near, which send towards the eye rays more divergent, and thereby less disposed to converge, through the effect of refraction in the crystalline and other humours. This imperfection is remedied by the use of a glass slightly concave.

MYOXUS, *dormouse*, a genus of quadrupeds of the order glires: the generic character is, front-teeth two, the upper cuneated, the lower compressed; grinders four in each jaw; vibrissæ long; tail cylindric, villose, thicker towards the end; legs of equal length, fore-feet tetradactylous. These animals feed only on vegetables, and burrow in the ground, in which they continue during the winter in a torpid state. They are nocturnal, sleeping in their habitations the greater part of the day; they carry food to their mouths with their fore-paws, setting erect; and advance by leaps of several feet at a time, instead of walking. There are four species.

M. glis, or the fat, dormouse is found in Germany and Russia, and has much of the manners of a squirrel, haunting trees and feeding on fruits and nuts which it stores for its winter consumption. It was highly valued by the Romans as an article of food. It is six inches long to the tail, which is about four. It is not easily tamed.

M. muscardinus, or the common dormouse, is nearly of the size of a mouse, and inhabits thick hedges, making its nest in the hollow of some tree. It forms a hoard for the winter, during which it is for the greater part abstinent and torpid. It occasionally is roused by the intervention of temperate days, recurs to its stock, and then returns to its slumbers, till spring recovers it to daily exertion.

MYRICA, *gale* or *sweet-willow*, a genus

of the tetrandria order, in the diœcia class of plants; and in the natural method ranking under the 5th order, amentaceæ.

1. The *gale*, Dutch myrtle, or sweet-willow, grows naturally upon bogs in many places both of Scotland and England. It rises about four feet high.

2. The *cerifera*, wax-bearing myrica, or candleberry myrtle, is a native of North America. It is a small tree, about 10 or 12 feet high, with crooked stems branching forth near the ground irregularly.

There is a variety of this species of lower growth, with shorter but broader leaves, and of equal fragrance. This grows commonly in Carolina; where the inhabitants collect from its berries a wax of which they make candles, and which occasions its being called the candleberry tree. It delights in a moist soil.

MYRISTICA, *nutmeg-tree*, a genus of the diœcia syngenesia class and order. Nat. ord. of lauri. Calyx trifid; corolla none; male, filament columnar; anthers terminating, united; female, capsule superior, drupaceous, two valved; nut involved in an aril, called the mace. There are three species, of which *M. aromatica*, aromatic or true nutmeg-tree, grows to a considerable size in the East Indies.

MYRMECOPHAGA, the *ant-eater*, in natural history, a genus of Mammalia, of the order Bruta. Generic character: no teeth; tongue extensile and cylindric; mouth elongated into a form somewhat tubular; body covered with hair. They subsist on insects, and particularly that species of them from which they are designated. Thrusting their tongue into a nest of ants, the glutinous substance which exudes from it, serves to attach to it inextricably numbers of these insects, and when the animal perceives, by the exquisite feelings of the papillæ, that he has secured a sufficient number, he withdraws his tong and swallows his victims. There are seven species.

MYRMELEON, a genus of insects of the order neuroptera: the generic character is, mouth furnished with jaws, teeth two; feelers four, elongated; stemmata none; antennæ elevated, of the length of the thorax; wings deflected; tail of the male furnished with a forceps consisting of two straightish filaments. Of this genus the species history is best understood is the myrmeleon formicaleo of Linnæus, whose larva has long been celebrated by naturalists for its wonderful ingenuity, in preparing a kind of pitfal or deceptive cavity for the destruction of such insects as happen unwarily to enter it. The myrmeleon formicaleo, in its complete or fly state, bears some resemblance to a small dragon-fly, from which, however, it may readily be distinguished by its antennæ.

MYROXYLUM, a genus of the monogynia order, in the decandria class of plants. The calyx is campanulated; the superior petal larger than the rest; the germ is longer than the corolla; the legumen monospermous. There is but one species, the Peruiferum, a native of Peru and the warmer part of Africa. It is this shrub that yields the balsam of Peru, which is said to be extracted from it by coction in water. This balsam, as brought to us, is nearly of the consistence of thin honey, of a reddish brown colour inclining to black, and an agreeable aromatic flavour.

MYRRH, a gummy resinous concrete juice. The plant from which this substance is obtained, is not certainly known. According to Bruce, it belongs to the genus mimosa, and grows in Abyssinia and Arabia. It is in the form of tears. Colour reddish-yellow, sometimes transparent, but more frequently opaque. Taste brittle and aromatic. Does not melt when heated, and burns with difficulty. With water it forms a yellow solution. The solution in alcohol becomes opaque when mixed with water. By distillation it yields oil.

MYRTUS, the *myrtle*; a genus of the monogynia order, in the icosandria class of plants; and in the natural method ranking under the 19th order, hesperidæ. The calyx is quinquefid, superior; there are five petals; the berry is dispermous or trispermous. There are between fifty and sixty species. This genus is composed of small trees and shrubs; flowers some solitary, with two scales at the base; in others forming opposite corymbs or panicles, axillary or terminating. The *M. communis*, common myrtle, is a native of Asia, Africa, and the south of Europe. The *pimento*, or allspice tree, is about thirty feet in height, and two in circumference. It is a native of New Spain, and the West Indies. The flavour and fruit have an highly aromatic fragrance.

MYSTERY. This is a relative term and is of much the same import as the word *interpretation*, or the term antitype, and always refers to some obscure hint that went before, either by word, thing, or action, of which it is the real intent or meaning. Every emblematical speech or action, contains some hidden meaning beyond that which is first presented to the senses, and that internal, or secret *meaning*, once made known to us, the parable is explained, and every idea of secrecy, intricacy, or doubt is removed.

MYTHOLOGY, the history of the fabulous gods and heroes of antiquity, with the explanations of the mysteries or allegories couched therein. Lord Bacon thinks, that a great deal of concealed instruction and allegory was originally intended in most part of the ancient mythology. He observes, that some fables discover a great and evident similitude, relation, and connection, with the thing they signify, as well in the structure of the fable, as in the meaning of the names whereby the persons or actors, are characterised.

The same writer thinks it may pass for a further indication of a concealed and secret meaning, that some of these fables are so absurd and idle in their narration, as to shew an allegory even afar off; but the argument of most weight upon this subject he takes to be this, that many of these fables appear by no means to have been invented by the persons who relate them. He looks on them not as the product of the age, nor invention of the poets, but as sacred relics, as he terms them, gentle whispers, and the breath of better times, that from the tradition of more ancient nations came at length into the flutes and trumpets of the Greeks. He concludes

that the knowledge of the early ages was either great or happy; great if they by design made this use of trope and figure; of happy, if whilst they had other views, they afforded matter and occasion to such noble contemplations.

MYTILLUS, the *mussel*, a genus of insects of the vermes testacea class and order. Animal allied to an ascida; shell bivalve, rough, generally affixed by a byssus, or beard of silken filaments; hinge mostly without teeth, with generally a subulate, excavated, longitudinal line. There are between fifty and sixty species.

M. margaritiferus, which inhabits the American and Indian Seas, is about eight inches long, and something broader; the inside is beautifully polished, and produces true mother-of-pearl, and frequently the most valuable pearls. *M. edulis* inhabits Europe and Indian sea, found in large beds, adhering to other bodies by means of a long silky beard: the fish affords a rich food, but is often noxious to the constitution.

MYXINE, the *hag*: a genus of insects belonging to the order of vermes intestina. It has a slender body, carinated beneath, mouth at the extremity, cirrated: the two jaws pinnated; an adipose or rayless fin round the tail and under the belly. *M. glutinosa*, about eight inches long. It inhabits the ocean; enters the mouths of fish when on the hooks of lines that remain a-tide under water, and totally devours the whole, except the skin and bones.

N.

N, Or *n*, the thirteenth letter, and tenth consonant of our alphabet: it is a liquid, the sound of which is formed by forcing the voice strongly through the mouth and nostrils; being at the same time intercepted by applying the tip of the tongue to the fore-part of the palate, with the lips open. It suffers no consonant immediately after it, in the beginning of words and syllables; nor any before it, except *g*, *k*, and *s*, as in *gnaw*, *know*, *snow*, &c. as a numeral N stands for 900; and with a dash over it, thus $\overline{N}$ for 900,000; N, or N^{o}, stands for numero.

NABOB, properly *Nawab*, the plural of Naib, a deputy. As used in Bengal, it is the same as *Nazim*. It is also a title given to the wives and daughters of princes as well as to the princes themselves.

NABONASSAR, or *Æra of Nabonassar*, a method of computing time from the commencement of Nabonassar's reign. The epocha of Nabonassar is of the greater importance, as Ptolemy and other astronomers account their years from it.

NADIR, in astronomy, that point of the heavens which is diametrically opposite to the zenith, or point directly over our heads. The zenith and nadir are the two poles of the horizon.

NAILS, *of the fingers and toes*, consist of coagulated ablumen, with a little phosphate of lime.

NAILS, in building, &c. small spikes of iron, brass, &c. which being driven into wood, serve to bind several pieces together, or to fasten something upon them. The several sorts of nails are very numerous: as, 1. Back and bottom nails, with flat shanks to hold fast, and not open the wood. 2. Clamp-nails, for fastening the clamps in buildings, &c. 3. Clasp-nails, the heads of which, clasping and sticking into the wood, render the work smooth, so as to admit a plane over it. 4. Clench-nails, used by boat and barge-builders. 5. Clout-nails, used for nailing on clouts to axle-trees. 6. Deck-nails, for fastening of decks in ships, doubling of shipping, and floors laid with planks. 7. Dog-nails, for fastening hinges on doors, &c. 8. Flat-points, much used in shipping, and proper where there is occasion to draw and hold fast, and no conveniency of clenching. 9. Jobent nails, for nailing thin plates of iron to wood, as small hinges on cupboard doors, &c. 10. Lead-nails, for nailing lead, leather, and canvas, to hard wood. 11. Port-nails, for nailing hinges to the ports of ships. 12. Pound-nails, which are square, and are much used for pailing. 13. Ribbing-nails, principally used in ship-building, for fastening the ribs of ships in their places. 14. Rose-nails, which are drawn square in the shank, and commonly in a round tool. 15. Rother-nails, which have a full head, and are chiefly used in fastening rother-irons to ships. 16. Round-head nails, for fastening on hinges, or for any other use where a neat head is required. 17. Scupper-nails, which have a broad head, and are used for fastening leather and canvas to wood. 18. Sharp nails; these have sharp points and flat shanks, and are much used for nailing soft wood. 19. Sheathing-nails, for fastening sheathing boards to ships. 20. Square nails, which are used for hard wood, and nailing up wall-fruit. 21. Tacks, the smallest of which serve to fasten paper to wood, the middling for wool-cards, &c. and the larger for upholsterers and pumps.

Nails are said to be toughened when too brittle, by heating them in a fire-shovel, and putting some tallow or grease among them.

NAIL, is also a measure of length, containing the sixteenth part of a yard.

NAPHTHA. A native combustible liquid, of a yellowish-white colour; perfectly fluid and shining. It feels greasy, exhales an agreeable bituminous smell, and has a specific gravity of about 0.7. It takes fire on the approach of flame, affording a bright white light. It occurs in considerable springs on the shores of the Caspian Sea, in Sicily and Italy. It is used instead of oil, and differs from the petroleum obtained by distilling coal tar, only by its greater purity and lightness.

NARCISSUS, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 9th order, spathaceæ. There are six petals; the

nectarium is funnel shaped and monophyllous; the stamina are within the nectarium. There are 15 species with numerous varieties.

The bastard narcissus, or common yellow English daffodil, grows wild in great plenty in many of our woods and coppices, and under hedges, in several parts of England. Its commonness renders it of but little esteem with many; considered, however, as an early and elegant flower, of exceeding hardiness and easy culture, it merits a place in every garden, especially the double.

NARCOTICS, in medicine, soporiferous medicines, which excite a stupefaction. See Opium.

NARDUS, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the 4th order, gramina. There is no calyx; the coralla [illegible] bivalved. There are three species. This plant was [illegible] valued by the ancients both as an article of luxury and medicine. The unguentum nardinum was used at baths and feasts as a favourite perfume. Its value is evident from that passage of scripture, where our Saviour's head was anointed with a box of it, with which Judas found fault.

NARRATION, in oratory and history, a recital or rehearsal of a fact as it happened, or when it is supposed to have happened. Narration is of two kinds, either simple or historical, as where the auditor or reader is supposed to hear or read of a transaction at second hand; or artificial and fabulous, as where their imaginations are raised, and the action as it were is reacted before them.

NATIONAL DEBT. The stocks or public funds, are loans advanced to government, for which interest is regularly paid from revenues set apart for the purpose. This mode of raising supplies by levying taxes for the payment of the interest is called "The Funding System," and the loans thus raised, constitute "The National Debt."

The different funds or stocks are variously denominated, according to the terms on which they were established. Thus some are called the 3, some the 4 per cents, &c. and the manner of buying stock is, to give a specific sum for a nominal hundred. If for instance, the price of the 3 per cents. is 60*l.* this sum is paid for 100*l.* stock which yields a dividend of 3*l.* a year, that is 5*l.* per cent. per annum. When stocks are low, the interest is high, and *vice versa.* New loans are paid by instalments of 10 to 15 per cent. at stated periods and they generally comprehend different kinds, of stock, which together are called *Omnium.* If these be disposed of separately before all the instalments are paid, the different articles, are called *Scrip,* which is an abbreviation for *Subscription.*

NATRON. Native carbonate of soda, of which there are two kinds, the common and radiated. See Soda.

NATURAL HISTORY. The object of this branch of science may be divided into two heads; the first teaches us the characteristics, or distinctive marks of each individual object, whether animal, vegetable, or mineral; the second makes us acquainted with all its peculiarities, as to its habits, its qualities, and its uses. To assist in attaining the first, it is necessary to adopt some system of classification, in which individuals that agree in particular points may be arranged together. In this work we have adopted the Linnæan system, as the most simple and perfect that has been presented to the public. A knowledge of the second head is only gained by a patient investigation of each particular object. The study of natural history consists in the collection, arrangement, and exhibition, of the various productions of the earth. These are divided into the three grand kingdoms of nature, the boundaries of which meet together in the zoophytes. Minerals inhabit the interior parts of the earth in rude and shapeless masses. They are bodies concrete without life and sensation. Vegetables clothe the surface with verdure, imbibe nourishment through bibulous roots, breathe by leaves, and continue their kind by the dispersion of seed within prescribed limits. They are organized bodies, and have life, but not sensation. Animals adorn the exterior parts of the earth, respire and generate eggs; are impelled to action by hunger, affections, and pain: and by preying on other animals and vegetables, restrain within proper bounds and proportions the numbers of both. They have organized bodies, and have life, sensation, and the power of loco motion. Man, the governor and subjugator of all other beings is, by his wisdom alone, able to form just conclusions from such things as present themselves to his senses, which consist of natural bodies. Hence the first step of wisdom is to know these bodies; and to be able by marks imprinted on them by the God of nature, to distinguish them from each other, and to affix to every object its proper name. The Linnæan system is divided into five branches, each subordinate to the other; these are, class, order genus, species, and variety, with their names and characters. In this arrangement, the classes and orders are arbitrary, the genera and species are natural. Of the three grand divisions above referred to, the animal kingdom ranks highest in comparative estimation; next the vegetable, and last the mineral kingdom.

Animals enjoy sensation by means of a living organization, animated by a meddulary substance: perception by nerves; and motion by the exertion of the will. They have members for the different purposes of life; organs for their different senses; and faculties or powers for the application of their different perceptions. They all originate from an egg. Their external and internal structure, habits, instincts, and various relations to each other, will be found under the different genera.

The following is a brief abstract of the arrangement pursued by Linnæus in his division of the animal kingdom.

CLASS I. MAMMALIA.

ORDER.

Primates
Bruta
Feræ
Glires
Pecora
Belluæ
Cete

CLASS II. AVES.

ORDER.

Accipetres
Picæ
Anseres
Grallæ
Gallinæ
Passeres

CLASS III. AMPHIBIA.

ORDER.

Reptilia
Serpentes

CLASS IV. PISCES.

ORDER.

Apodes
Jugulares
Thoracici
Abdominales
Branchiostegi
Condropterygii

CLASS V. INSECTA.

ORDER.

Coleoptera
Hemyptera
Lepidoptera
Neuroptera
Hymenoptera
Diptera
Aptera

CLASS VI. VERMES.

ORDER.

Intestina
Mollusca
Tetascea
Zoophyta
Infusoria

NATURAL PHILOSOPHY, is that science which considers the powers of nature, the properties of nutual bodies, and their actions on one another. This science is necessarily of great extent, and the leading branches of it will be found treated under the following heads, viz. *Astronomy, Chemistry, Electricity, Galvanism, Hydraulics, Hydrostatics, Magnetism, Mechanics, Optics,* and *Pneumatics,* &c. See also EXPERIMENTAL PHILOSOPHY.

NAVIGATION, is the art of conducting a vessel from one port to another by observation of the heavenly bodies, calculation of the distance, or way, made daily, and by steering such a course, under guidance of the compass, as may lead, in the most direct manner, from the place quitted to the ship's destination.

The student of navigation should have a thorough knowledge of geography; especially of the divisions of the globe by the various circles and meridians by which it is intersected in theory. He ought also to be well acquainted with all relating to the needle; particularly what relates to the dip and variations, and be able to take an account of the ship's progress numerically, or, as it is termed in dead reckoning; and if he should possess some skill in geometry and trigonometry, he will find that his task is more easily performed, and that he will, in due time, render himself conspicuous in that branch of his profession.

The names of the two great divisions of navigation, are taken merely from the kind of charts made use of. Plane sailing is that in which the plane chart is made use of; and Mercator's sailing, or globular sailing, is that in which Mercator's chart is used.

Of plane sailing. As a necessary preliminary to our understanding this method of navigation, we shall here give the construction of the plane chart.

1. This chart supposes the earth to be a plane, and the meridians parallel to one another; and likewise the parallels of latitude at equal distances from one another, as they really are upon the globe. Though this method is in itself evidently false; yet, in a short run, and especially near the equator, an account of the ship's way may be kept by it tolerably well.

Having determined the limits of the chart, that is, how many degrees of latitude and longitude, or meridional distance, (they being in this chart the same), it is to contain: suppose from the lat. of 20° N. to the lat. of 71° N. and from the longitude of London in 0 deg. to the long. of 50° W.; then choose a scale of equal parts, by which the chart may be contained within the size of a sheet of paper on which it is intended to be drawn.

Make a parallelogram A B C D, Plate XXXVII, fig. 1, the length of which AB from north to south shall contain 51 degrees, the difference of latitude between the limits of 20° and 71°; add the breadth AD from east to west shall contain the proposed 50 degrees of longitude, the degrees being taken from the said scale, and this parallelogram will be the boundaries of the chart.

About the boundaries of the chart make scales containing the degrees, halves, and quarters of degrees (if the scale is large enough;) drawing lines across the chart through every 5 or 10 degrees.

On a straight slip of pasteboard, or stiff paper, let the scale of the degrees and parts of degrees of longitude, in the line AD, be laid close to the edge; and the divisions numbered from the right hand towards the left, being all west longitude.

Seek in a geographical table for the latitudes and longitudes of the places contained within the proposed limits.

Then, to lay down any places lay the edge to the pasteboard scale to the divisions on each side the chart, shewing the latitude of the place, so that the beginning of its divisions falls on the right-hand border AB; and against the divisions shewing the longitude of the given place make a point, and this gives the position of the place proposed; and in like manner are all the other places to be laid down.

Draw waving lines from one point to the other, where the coast is contiguous, and thus the representation of the lands within the proposed limits will be delineated.

Write the names to the respective parts, and in some convenient place insert a compass, and the chart will be completed.

2. The angle formed by the meridian and rhumb that a ship sales upon, is called, the ship's course. Thus, if a ship sails on the N.N.E. rhumb, then her course will be 22° 30′: and so of others.

3. The distance between two places lying on the same parallel counted in miles of the equator, or the distance of one place from the meridian of another counted as above on the parallel passing over that place, is called meridional distance; which, in plane sailing, goes under the name of departure.

4. Let A, fig. 2, denote a certain point on the earth's surface, AC its meridian, and AD the parallel of latitude passing through it, and suppose a ship to sail from A on the N. N. E. rhumb till she arrives at B; and through B draw the meridian BD, (which according to the principles of plane sailing, must be parallel to CA,) and the parallel of latitude BC; then the length of AB, viz. how far the ship has sailed upon the N.N.E. rhumb, is called her distance; AC or BD will be her difference of latitude, or nothing; CB will be her departure, or easting; and the angle CAB will be her course.

5. Since the distance, difference of latitude,

and departure, form a right-angled triangle, in which the oblique angle opposite to the departure is the course, and the other its complement; therefore, having any two of these given, we can (by plane trigonometry) find the rest; and hence arise the cases of plane-sailing, which are as follow.

Case I. Course and distance given, to find the difference of latitude and departure.

Example. Suppose a ship sales from the latitude of 30° 25′ north, N.NE. 32 miles (fig. 3). Required the difference of latitude and departure, and the latitude come to. Then (by right-angled trigonometry) we have the following analogy for finding the departure, viz.

As radius		10.00000
to the distance AC	32.	1.50515
so is the sine of the course A	22° 30′	9.58284
to the departure BC	12.25	1.08799

so the ship has made 12.25 miles of departure easterly, or has got so far to the eastward of her meridian. Then for the difference of latitude or northing the ship has made, we have (by rectangular trigonometry) the following analogy, viz.

As radius		10.00000
is to the distance AC	32	1.50515
so is the co-sine of course A	22° 30′	9.53284
to the difference of lat. AB	29.57	1.47077

so the ship has differed her latitude, or made of northing, 29.57 minutes.

And since her former latitude was north, and her difference of latitude also north; therefore,

To the latitude sailed from	30°, 25′ N
add the difference of latitude	00°, 29.57
and the sum is the latitude come to	30°, 54.57′ N.

By this case are calculated the tables of difference of latitude, and departure, to every degree, point, and quarter-point, of the compass.

Case II. Course and difference of latitude given, to find distance and departure.

Example. Suppose a ship in the latitude of 45° 25′ north, sails NE*b*N¼ easterly. fig. 4, till she comes to the latitude of 46° 55′ north: required the distance and departure made good upon that course.

Since both latitudes are northerly, and the course also northerly; therefore,

From the latitude come to	46°, 55′
subtract the latitude sailed from	45°, 25′
and there remains	01°, 30′

the difference of latitude, equal to 90 miles.

And (by rectangular trigonometry) we have the following analogy for finding the departure BD, viz.

As radius		10.00000
is to the diff. of latitude AB	90	1.95424
so is the tangent of course A	39° 22′	9.91401
to the departure BD	73.84	1.86828

so the ship has got 73.84 miles to the eastward of her former meridian.

Again, for the distance AD, we have (by rectangular trigonometry) the following proportion, viz.

As radius		10.00000
is to the secant of the course	39°, 22′	10.11176
so is the diff. of latitude AB	90	1.95424
to the distance AD	116.4	2.06600

Case III. Difference of latitude and distance given, to find course and departure.

Example. Suppose a ship sails from the latitude of 56° 50 north, on a rhumb between south and west, 126 miles, and she is then found by observation to be in the latitude of 55°, 40 north: required the course she sailed on, and her departure from the meridian. Fig. 5.

Since the latitudes are both north, and the ship sailing towards the equator; therefore,

From the latitude sailed from	56°, 50′
subtract the observed latitude	55, 10′
and the remainder	01°, 40′

equal to 70 miles, is the difference of latitude.

By rectangular trigonometry we have the following proportion for finding the angle of the course F, viz.

As the distance sailed DF	126	2.10037
is to radius		10.00000
so is the diff. of latitude FD	70	1.84510
to the co-sine of the course F	56°, 15′	9.74473

which, because she sails between south and west will be south 56° 15′ west, or SW*b*W. Then for the departure, we have (by rectangular trigonometry) the following proportion, viz.

As radius		10.00000
is to the distance sailed DF	126	2.10037
so is the sine of the course F	56°, 15′	9.91985
to the departure DE	104.8	2.02022

consequently she has made 104.8 miles of departure westerly.

Case IV. Difference of latitude and departure given, to find course and distance.

Example. Suppose a ship sails from the latitude of 44° 50′ north, between south and east, till she has made 64 miles of easting, and is then found by observation to be in the latitude of 42° 56′ north; required the course and distance made good.

Since the latitudes are both north, and the ships sailing towards the equator; therefore,

From the latitude sailed from	44°, 50′ N
take the latitude come to	42°, 56′
and there remains	01°, 54′

equal to 114 miles, the difference of latitude or southing.

In this case by rectangular trigonometry we have the following proportion to find the course KGL, fig. 6, viz.

As the diff. of latitude GK	114	2.05690
is to radius		10.00000
so is the departure KL	64	1.80618
to the tangent of course G	29°, 19′	9.74928

which, because the ship is sailing between south and east, will be south 29° 19′ east, or SSE½ east nearly.

Then for the distance, we shall have by rectangular trigonometry the following analogy, viz.

As radius		10.00000
is to the diff. of latitude GK	114	2.05690
so is the secant of the course	29°, 19′	10.05952
to the distance GL	130.8	2.11642

consequently the ship has sailed on a SSE½ east course 130.8 miles.

Case. 5. Distance and departure given, to find course and difference of latitude.

Example. Suppose a ship at sea sails from the latitude of 34° 24′ north, between north and west, 124 miles, and is found to to have made of westing 86 miles: required the course steered, and the difference of latitude or northing made good.

In this case, by rectangular trigonometry, we have the following proportion for finding the course ADB, fig. 7, viz.

As the distance AD	124	2.09342
is to radius		10 00000
so is the departure AB	86	1.93450
to the sine of the course D	43° 54'	9.84108

so the ship's course is north 33° 45' west, or NWbN¼ west nearly.

Then for the difference of latitude, we have, by rectangular trigonometry, the following analogy, viz.

As radius		10.00000
is to the distance AD	124	2.09342
so is the co-sine of the course	43°, 54'	9.85766
to the diff. of latitude BD	89.35	1.95108

which is equal to 1 degree and 29 min. nearly.

Hence, to find the latitude the ship is in, since both latitudes are north, and the ship sailing from the equator; therefore,

To the latitude sailed from	34°, 24'
add the difference of latitude	1°, 29'
the sum is	35°, 53'

the latitude the ship is in north.

CASE. 6. Course and departure given, to find distance and difference of latitude.

Example. Suppose a ship at sea, in the latitude of 24° 30' south, sails SEbS, till she has made of easting 96 miles: required the distance and difference of latitude made good on that course.

In this case by rectangular trigonometry, and by case 2, we have the following proportion for finding the distance, fig. 8, viz.

As the sine of the course G	33°, 45'	9.74474
is to the departure HM	96	1.98227
so is radius		10 00000
to the distance GM	172 8	2.23753

Then, for the difference of latitude, we have by rectangular trigonometry, the following analogy, viz.

As the tangent of course	33°, 45'	9.82489
is to the departure HM	96	1.98227
so is radius		10.00000
to the difference of lat. GH	143.7	2.15738

equal to 2°, 24' nearly. Consequently, since the latitude the ship sailed from was south, and she sailing still towards the south,

To the latitude sailed from	24°, 30'
add the difference of latitude	2°, 25'
and the sum	26°, 54'

is the latitude she is come to south.

6. When a ship sails on several courses in 24 hours, the reducing all these into one, and thereby finding the course and distance made good upon the whole, is commonly called the resolving of a traverse.

7. At sea they commonly begin each day's reckoning from the noon of that day, and from that time they set down all the different courses and distances sailed by the ship till noon next day upon the log-board; then from these several courses and distances, they compute the difference of latitude, and departure for each course (by case I of Plane Sailing ;) and these together with the courses and distances, are set down in a table, called the Traverse Table, which consists of five columns: in the first of which are placed the courses and distances; in the two next, the differences of latitude belonging to these courses, according as they are north or south: and in the two last are placed the departures belonging to these courses, according as they are east or west. Then they sum up all the northings and all the southings; and taking the difference of these, they know the difference of latitude made good by the ship in the last 24 hours, which will be north or south, according as the sum of the northings, or southings is greatest: the same way, by taking the sum of all the eastings, and likewise of all the westings and subtracting the lesser of these from the greater, the difference will be the departure made good by the ship last 24 hours, which will be east or west according as the sum of the eastings is greater or less than the sum of the westings; then from the difference of latitude and departure made good by the ship last 24 hours, found as above, they find the true course and distance made good upon the whole, by case 4 of Plane Sailing, as also the course and distance to the intended port.

Of Parallel Sailing. Since the parallels of latitude do always decrease the nearer they approach the pole, it is plain a degree on any of them must be less than a degree upon the equator. Now, in order to know the length of a degree on any of them, let PB fig. 9, represent half the earth's axis, PA a quadrant of a meridian, and consequently A a point on the equator, C a point on the meridian, and CD a perpendicular from that point upon the axis, which plainly will be the sine of CP the distance of that point from the pole, or the co-sine of CA its distance from the equator; and CD will be to AB, as the sine of CP, or co-sine of CA, is to the radius. Again, if the quadrant PAB is turned round upon the axis PB, it is plain the point A will describe the circumference of the equator whose radius is AB, and any other point C upon the meridian will describe the circumference of a parallel, whose radius is CD.

Cor. 1. Hence, because the circumference of circles are as their radii, it follows, that the circumference of any parallel is to the circumference of the equator, as the co-sine of its latitude is to radius.

Cor. 2. And since the wholes are as their similar parts, it will be, as the length of a degree on any parallel, is to the length of a degree upon the equator, so is the co-sine of the latitude of that parallel, to radius.

Cor. 3. Hence, as radius, is to the co-sine of any latitude, so are the minutes of difference of longitude between two meridians, or their distance in miles upon the equator, to the distance of these two meridians on the parallel in miles.

Cor. 4. And, as the co-sine of any parallel, is to radius, so is the length of any arch on that parallel, intercepted between two meridians, in miles, to the length of a similiar arch on the equator, or minutes of difference of longitude.

Cor. 5. Also, as the co-sine of any one parallel, is to the co-sine of any other parallel, so is the length of any arch on the first in miles, to the length of the same arch on the other in miles.

Of Mercator's Sailing. Though the meridians do all meet at the pole, and the parallels to the equator do continually decrease, and that in proportion to the co-sines of their latitudes; yet in old sea-charts the meridians were drawn parallel to one another and con-

sequently the parallels of latitude made equal to the equator, and so a degree of longitude on any parallel as large as a degree on the equator; also in these charts the degrees of latitude were still represented, as they are in themselves, equal to each other, and to those of the equator. By these means the degrees of longitude being increased beyond their just proportion, and the more so the nearer they approach the pole, the degrees of latitude at the same time remaining the same, it is evident places must be very erroneously marked down upon these charts with respect to their latitude and longitude, and consequently their bearing from one another very false. To remedy this inconvenience, so as still to keep the meridians parallel, it is plain we must protract, or lengthen, the degrees of latitude in the same proportion as those of longitude are, that so the proportion in easting and westing may be the same with that of southing and northing, and consequently the bearings of places from one another are the same upon the chart as upon the globe itself.

Let ABD, fig. 10, be a quadrant of a meridian, A the pole, D a point on the equator, AC half the axis, B any point upon the meridian, from which draw BF perpendicular to AC, and BG perpendicular to CD; then BG will be the sine, and BF or CG the co-sine, of BD the latitude of the point B; draw DE the tangent and CE the secant of the arch CD. It has been demonstrated, that any arch of a parallel is to the like arch of the equator, as the co-sine of the latitude of that parallel is to radius. Thus any arch, as a minute on the parallel described by the point B, will be to a minute on the equator, as BF or CG is to CD; but since the tringles CGB, CDE, are similar, therefore CG will be to CD as CB is to CE, *i. e.* the co-sine of any parallel is to radius, as radius is to the secant of the latitude of that parallel. But it has been just now shown, that the co-sine of any parallel is to radius, as the length of any arch on that parallel is to the length of the like arch on the equator; therefore the length of any arch on any parallel, is to the length of the like arch on the equator, as radius is to the secant of the latitude of that parallel; and so the length of any arch, on the equator, is longer than the like arch of any parallel, in the same proportion as the secant of the latitude of that parallel is to radius.

But since in this projection the meridians are parallel, and consequently each parallel of latitude equal to the equator, it is plain the length of any arch, as a minute, on any parallel, is increased beyond its just proportion, at such rate as the secant of the latitude of that parallel is greater than radius; and therefore to keep up the proportion of northing and southing to that of easting and westing, upon this chart, as it is upon the globe itself, the length of a minute upon the meridian at any parallel must also be increased beyond its just proportion at the same rate, *i. e.* as the secant of the latitude of that parallel is greater than radius. Thus, to find the length of a minute upon the meridian at the latitude of 75 degrees, since a minute of a meridian is every where equal on the globe and also equal to a minute upon the equator, let it be represented by unity; then making it as radius to the secant of 75 degrees, so is unity to a fourth number, which is 3.864 nearly; and consequently, by whatever line you represent one minute on the equator of this chart, the length of one minute on the enlarged meridian at the latitude of 75 degrees, or the distance between the parallel of 75° 00′ and the parallel of 75° 01′, will be equal to 3 of these lines, and $\frac{864}{1000}$ of one of them. By making the same proportion, it will be found that the length of a minute on the meridian of this chart at the parallel of 60°, or the distance between the parallel of 60° 00′ and that of 60° 01′, is equal to two of these lines. After the same manner, the length of a minute on the enlarged meridian may be found at any latitude; and consequently beginning at the equator, and computing the length of every intermediate minute between that and any parallel, the sum of all these shall be the length of a meridian intercepted between the equator and that parallel; and the distance of each degree and minute of latitude from the equator upon the meridian of this chart, computed in minutes of the equator, forms what is commonly called a table of meridional parts.

If the arch BD, fig. 10, represents the latitude of any point B, then, CD being radius, CE will be the secant of that latitude; but it has been shown above, that radius is to secant of any latitude, as the length of a minute upon the equator is to the length of a minute on the meridian of this chart at that latitude; therefore CD is to CE, as the length of a minute on the equator is to the length of a minute upon the meridian at the latitude of the point B. Consequently, if the radius CD is taken equal [illegible] length of a minute upon the equ[illegible] or the secant of the latitude, will be equal to the length of a minute upon the meridian at that latitude. Therefore, in general, if the length of a minute upon the equator is made radius, the length of a minute upon the enlarged meridian will be every where equal to the secant of the arch contained between it and the equator.

Hence it follows, since the length of every intermediate minute between the equator and any parallel is equal to the secant of the latitude, the radius being equal to a minute upon the equator, the sum of all these lengths, or the distance of that parallel on the enlarged meridian from the equator, will be equal to the sum of all the secants to every minute contained between it and the equator. Consequently, the distance between any two parallels on the same side of the equator, is equal to the difference of the sums of all the secants contained between the equator and each parallel: and the distance between any two parallels on contrary sides of the equator, is equal to the sum of the sums of all the secants contained between the equator and each parallel.

By the tables of meridional parts given by all the writers on this subject, may be constructed the nautical chart, commonly called Mercator's chart. See Maps.

In fig. 11, let A and E represent two places upon Mercator's chart, AC the meridian of A, and CE the parallel of latitude passing through

E; draw AE, and set off upon AC the length AB equal to the number of minutes contained in the difference of latitude between the two places, and taken from the same scale of equal parts the chart was made by, or from the equator, or any graduated parallel of the chart, and through B draw BD parallel to CE meeting AE in D. Then AC will be the enlarged difference of latitude, AB the proper difference of latitude, CE the difference of longitude, BD the departure, AE the enlarged distance, and AD the proper distance, between the two places A and E; also the angle BAD will be the course, and AE the rhumb-line between them.

Of Oblique Sailing. The questions that may be proposed on this head being innumerable, we shall only give one as a specimen.

Coasting along the shore, I saw a cape bear from me NNE: then I stood away NW*b*W 20 miles, and I observed the same cape to bear from me NE*b*E: required the distance of the ship from the cape at each station.

Geometrically. Draw the circle NW SE, figure 21, to represent the compass, NS the meridian, and WE the east and west line, and let C be the place of the ship in her first station; then from C set off upon the NW*b*W line, CA 20 miles, and A will be the place of the ship in her second station.

From C draw the NNE line CB, and from A draw AB parallel to the NE*b*E line CD, which will meet CB in B, the place of the cape, and CB will be the distance of it from the ship in its first station, and AB the distance in the second: to find which,

By Calculation;

In the triangle ABC are given AC, equal to 20 miles; the angle ACB, equal to 78° 45′, the distance between the NNE and NW*b*W lines; also the angle ABC, equal to BCD, equal to 33° 45′, the distance between the NNE and NE*b*E lines; and consequently the angle A, equal to 67° 30′.

Hence, for CB, the distance of the cape from the ship in her first station, it will be, by oblique trigonometry,

S. ABC : AC :: S. BAC · CB.

i. e. As the sine of the angle B	33° 45′	9.74473
is to the distance run AC	20 —	1.30163
so is the sine of BAC -	67 30	9.96562
to CB - - - -	33.26	1.52191

the distance of the cape from the ship at the first station. Then for AB, it will be, by oblique trigonometry,

S. ABC : AC :: S. ACB : AB.

i. e. As the sine of B -	33° 45′	9.74474
is to AC - - -	20 —	1.30103
so is the sine of C -	78 45	9.99157
to AB - - -	35.31	1.54786

the distance of the ship from the cape at her second station.

Before quitting this article, we shall briefly notice Mr. Barlow's admirable discovery of a method of counteracting the local attraction of vessels. For this discovery, Mr. Barlow received the highest reward, viz. that of 500*l.* given by the Board of Longitude. The instrument, as constructed by Mr. Barlow, is thus described. The centre of a small circular plate of iron is placed in the line of the attraction of the ship's iron, and at a proper distance behind and below the pivot of the compass needle; the position of this line having been previously ascertained, an operation now rendered easy by the tables for this purpose prepared by Mr. Barlow, and given with the instrument. When this is done, the needle will remain active and vigorous in the polar regions, and will direct itself in the true magnetic meridian, in whatever part of the world the ship may be. This effect of Mr. Barlow's invention has been established by experiments, between the 61° of south latitude, and the 81° of north latitude, by the accurate observations of Lieutenant Foster, and other naval officers.

With respect to the plate itself, it has hitherto been made double, viz. of two plates screwed together, in such a manner as to combine any strong irregular power of the one with a like weak point in the other; by which means a more uniform attraction is obtained. The plates may vary from 12 to 16 inches in diameter, according to the power of the vessel. They have a hole in their centre, through which is passed a brass socket, with a broad head, and with an exterior screw or nut, by which the two plates and an interposed piece of wood of the same size are compressed strongly together, the board being intended to increase the thickness, without adding much to the weight; and it is found that the two plates thus separated, are more powerful than when in contact. Fig. 13, plate XXXVII, shews the whole combined as in action on ship board.

Navigation Inland. This term properly comprehends whatever relates to the navigation of lakes, rivers, and canals; to the last of these, the following remarks will be confined.

The advantages derived from inland navigation are now so well known, and so universally acknowledged, that nothing need be said on that head. Whatever may be said of the inland navigation of foreign countries, it has been far surpassed by that of Britain; upwards of 2400 miles have been made in England, constituting a congeries of inland navigation not to be equalled in the world; and in the construction of which, difficulties of all kinds have been encountered, and overcome.

This amazing extent of navigation owes its merits to the vigorous and persevering efforts of the Duke of Bridgewater, and others who followed his liberal and spirited example. This great improvement in the conveyance of commodities has arrived at a high degree of perfection, and enables us to transport them even over mountains where it would appear impossible to preserve a communication, or rather a continuity of water-carriage with the subjacent plains. This is effected by the means of locks built of masonry, each of which serves as the conjunction of two different levels. The locks are made only large enough to admit the vessels employed in the business, and have two gates, one at each end. When a vessel should ascend to a superior level, the upper gate is shut, and the vessel being brought within the lock, the lower gate is also closed, and the upper one opened. By this means the water flows in, and the vessel is raised to the intended height. The upper gate is closed as soon as the vessel has passed, but the water in the lock is preserved for the purpose of letting a vessel down, which is done by shutting the upper gate after she is in the lock, and opening the lower one; so that

she is lowered gradually to the next level. The water in all cases is let in or out by means of a small hatch, making its rise and fall very gradual; else the gates would be torn from their hinges by the rush of so large a body, and the vessel would be endangered. We have instances of about twenty locks all in half a mile's distance; but there require very powerful springs to supply a due quantity of water. Sometimes canals are raised above the level of the country; and we have instances where one canal passes over another.

NAUTILUS, in zoology, a genus belonging to the order of vermes testaceæ. The shell consists of one spiral valve, divided into several apartments by partitions. There are 17 species, chiefly distinguished by particularities in their shells. The most remarkable division of the nautili is into the thin and thick-shelled kinds. The first is called nautilus papyraceus; and its shell is indeed no thicker than a piece of paper when out of the water. This species is not at all fastened to its shell; but there is an opinion, as old as the days of Pliny, that this creature creeps out of its shell, and goes on shore to feed. When this species is to sail, it expands two of its arms on high, and between these supports a membrane which it throws out on this occasion; this serves for its sail: and the two other arms it hangs out of its shell, to serve occasionally either as oars or as a steerage; but this last office is generally served by the tail. When the sea is calm, it is common to see numbers of these creatures diverting themselves in this manner; but as soon as a storm rises, or any thing gives them disturbance, they draw in their legs, and take in as much water as makes them specifically heavier than that in which they float; and they sink to the bottom. When they rise again, they void this water by a number of holes, of which their legs are full.

NAVY, the fleet or shipping of a prince or state. The management of the British navy royal, under the Lord High Admiral of Great Britain, is entrusted to principal officers and commissioners of the navy, who hold their places by patent. The principal officers of the navy are four, viz. the Treasurer, whose business it is to receive money out of the exchequer, and to pay all the charges of the navy, by warrant from the principal officers: Comptroller, who attends and comptrols all payment of wages, is to know the rates of stores, to examine and audite all accounts, &c.: Surveyor, who is to know the states of all stores, and see wants supplied, to estimate repairs, charge boatswains, &c. with what stores they receive, and at the end of each voyage to state and audite accounts: Clerk of the Acts, whose business it is to record all orders, contracts, bills, warrants, &c.

The Commissioners of the navy are five: the first executes that part of the Comptroller's duty which relates to the comptrolling the Victualler's accounts; the second, another part of the said Comptroller's duty, relating to the account of the store-keepers of the yard; the third has the direction of the navy at the port of Portsmouth; the fourth has the same at Chatham; and the fifth at Plymouth. There are also other Commissioners at large, the number more or less, according to the exigencies of public affairs; and since the increase of the royal navy, these have several clerks under them, with salaries allowed by the king.

The victualling of the royal navy had formerly been undertaken by contract, but is now managed by Commissioners, who hold their office at Somerset House, Strand.

NAZARITES, among the Jews, persons who either of themselves, or by their parents, were dedicated to the observation of Nazariteship. They were of two sorts, namely, such as were bound to this observance for only a short time, as a week or month; and those who were bound to it all their lives. All that we find peculiar in the latter's way of life is, that they were to abstain from wine and all intoxicating liquors, and never to shave or cut off the hairs of their heads. The first sort of Nazarites were moreover to avoid all defilement; and if they chanced to contract any pollution before the term was expired, they were obliged to begin afresh.

NE ADMITTAS, in law, a writ directed to the bishop, at the suit of one that is patron of a church, where, on a quare impedit, &c. depending, he is doubtful that the bishop will collate his clerk, or admit the other's clerk, during the suit between them.

NEAT, or **Net-weight**, the weight of a commodity alone, clear of the cask, bag, case, or even filth.

NEBULÆ, in astronomy. There are spots in the heavens called nebulæ, some of which consist of clusters of telescopic stars, others appear as luminous spots of different forms. The most considerable is one in the midway between the two stars on the blade of Orion's sword, marked θ by Bayer, discovered in the year 1656 by Huygens; it contains only seven stars, and the other part is a bright spot upon a dark ground, and appears like an opening into brighter regions beyond. Dr. Halley and others have discovered nebulæ in different parts of the heavens. In the "Connoisance des Temps," for 1783 and 1784, there is a catalogue of 103 nebulæ observed by Messier and Mechain. But to Dr. Herschel we are indebted for catalogues of 2000 nebulæ, and clusters of stars, which he himself has discovered. Some of them form a round compact system, others are more irregular, of various forms, and some are long and narrow. He supposes, that the milky way is the nebulæ of which our sun is one of its component parts.

Dr. Herschel has also discovered other phenomena in the heavens, which he calls *nebulous stars;* that is, stars surrounded with a faint luminous atmosphere of large extent. Those which have been thus styled by other astronomers, he says, ought not to have been so called, being either mere clusters of stars plainly to be distinguished by his large telescopes, or such nebulous appearances as might be occasioned by a multitude of stars at a vast distance. The milky way consists entirely of stars.

NEBULY, or **Nebulee**, in heraldry, is when a coat is charged with several little figures, in form of words, running within one another, or when the outline of a bordure, ordinary, &c. is indented or waved.

NECESSITY. The law charges no man with default where the act is compulsory, and not voluntary, and where there are not a con-

rent and election; and therefore if either there is an impossibility for a man to do otherwise, or so great a perturbation of the judgment and reason as in presumption of law man's nature cannot overcome, such necessity carries a privilege in itself. Necessity is of three sorts; necessity of conservation of life, necessity of obedience, and necessity of the act of God, or of a stranger.

NECESSITY *Philosophical.* This subject, which stands in direct opposition to the freedom of the human will, has occasioned much discussion among the learned. The advocates of philosophical necessity affirm that the volitions and actions of intelligent agents are produced by causes equally deciding and resistless as those which are admitted to actuate the material system of the universe. See WILL.

NECK, is that slender part situated between the head and trunk of the body. See ANATOMY.

NECTARINE. See PERSICA.

NECTARIUM, in botany, according to Linnæus, is a part of the corolla, appropriated for containing honey, that oozes from the plant, and is the principal food of bees and other insects.

NEEDLE, a very common little instrument made of steel, pointed at one end, and pierced at the other, used in sewing. The sizes are from number 1, the largest, to number 25, the smallest. In the manufacture of needles, German and Hungarian steel are of most repute. In making them, the steel is passed through a coal fire, and under a hammer, to bring it out into a cylindrical form. This done, it is drawn through the holes of a wire-drawing-iron, successively, till it has acquired the degree of fineness required. The wire is then cut into pieces of the length intended. These pieces are flatted at one end on the anvil, in order to form the head and eye: they are then put into the fire to soften them further, and thence taken out and pierced at each extreme of the flat part of the anvil, with a puncheon of well tempered steel, and laid on a leaden block to bring out, with another puncheon, the little piece of steel remaining in the eye. The corners are then filed off the square of the heads, and a little cavity filed on each side of the flat of the head; the point is then formed with a file, and the whole filed over; they are then laid to heat red hot in a charcoal fire, and when taken out hence, are thrown out into a bason of cold water to harden. When thus hardened, they are laid in an iron shovel on a fire, more or less brisk in proportion to the thickness of the needles, taking care to move them from time to time. This serves to temper them, and take off their brittleness. They are then straightened one after another with the hammer. The next process is the polishing them. To do this, they take twelve or fifteen thousand needles, and range them in little heaps against each other on a piece of new buckram sprinkled with emery dust. The needles thus disposed, emery dust is thrown over them, which is again sprinkled with oil of olives; at last the whole is made up into a roll, well bound at both ends. This roll is then laid on a polishing-table, and over it a thick plank loaded with stone, which two men work backwards and forwards a day and a half, or two days, successively; by which means the roll, thus continually agitated by the weight and motion of the plank over it, the needles within side being rubbed against each other with oil and emery, are insensibly polished. They are then taken out, and the filth washed off them with hot water and soap: they are then wiped in hot bran, a little moistened, placed with the needles in a round box, suspended in the air by a cord, which is kept stirring till the bran and needles be dry. The points are then all turned the same way, and smoothed with an emery stone turned with a wheel. They are then done up into packets of two hundred and fifty each.

NEEDLE, *magnetical,* in navigation, a needle touched with a loadstone, and sustained on a pivot or centre: on which playing at liberty, it directs itself to certain points in or under the horizon. The magnetical needle is of two kinds, viz. horizontal and inclinatory.

Horizontal needles are those equally balanced on each side the pivot that sustains them, and which playing horizontally with their two extremes, point out the north and south points of the horizon.

Inclinatory or dipping needle, a magnetical needle, so hung, as that, instead of playing horizontally and pointing out north and south, one end dips or inclines to the horizon, and the other points to a certain degree of elevation above it. See COMPASS and MAGNETISM.

NEGATIVE, in general, something that implies a negation. Thus we say, negative quantities, negative signs, negative powers, &c. See ALGEBRA.

NEGRO, a name given to a variety of the human species, who are entirely black, and are found in the torrid zone, especially in that part of Africa which lies between the tropics.

NEPA, *water-scorpion,* a genus of insects of the order hemiptera. Snout inflected; antennæ short; wings four, folding cross-wise, coriaceous on the upper part; fore legs cheliform; the other four formed for walking. There are 14 species, inhabiting stagnant waters, and preying on the smaller water insects, &c.

NEPER's RODS, or BONES, an instrument invented by J. Neper, baron of Merchiston, in Scotland, whereby the multiplication and division of large numbers are much facilitated.

NEPER'S ROD, *the construction of.* Suppose the common table of multiplication to be made upon a plate of metal, ivory, or paste-board, and then conceive the several columns (standing downwards from the digits on the head) to be cut asunder; and these are what we call Neper's rods for multiplication. But then there must be a good number of each, for as many times as any figure is in the multiplicand, so many rods of that species (i. e. with that figure on the top of it) must we have; though six rods of each species will be sufficient for any example in common affairs; there must be also as many rods of 0's.

But before we explain the way of using these rods, there is another thing to be known, viz. that the figures on every rod are written in an order different from that in the table. Thus, the little square space or division in which the several products of every column are written, is divided into two parts by a line across from the upper angle on the right to the lower on the left; and if the product is

a digit, it is set in the lower division; if it has two places, the first is set in the lower, and the second in the upper division; but the spaces on the top are not divided. Also there is a rod of digits, not divided, which is called the index-rod; and of this we need but one single rod.

Multiplication by Neper's Rods.—Lay down the index-rod; then on the right of it set a rod whose top is the figure in the highest place of the multiplicand; next to this again, set the rod whose top is the next figure of the multiplicand; and so on in order to the first figure. Then is your multiplicand tabulated for all the nine digits; for in the same line of squares standing against every figure of the index-rod, you have the product of that figure, and therefore you have no more to do but to transfer the products, and sum them. But in taking out these products from the rods, the order in which the figures stand obliges you to a very easy and small addition: thus, begin to take out the figure in the lower part, or unit's place, of the square of the first rod on the right: add the figure in the upper part of this rod to that in the lower part of the next, and so on, which may be done as fast as you can look on them. To make this practice as clear as possible, take the following example.

Example.—To multiply 4768 by 185.

Having set the rods together for the number 4768, against 5 in the index I find this number,

by adding according to the rule -	23840
Against 8 this number - -	38144
Against 3 this number - -	14304
Total product - - - -	1835680

Division by Neper's Rods.—Tabulate your divisor; then you have it multiplied by all the digits, out of which you may choose such convenient divisors as will be next less to the figures in the dividend, and write the index answering in the quotient, and so continually, till the work is done. Thus 2,179,788, divided by 6,123, gives in the quotient 356.

Having tabulated the divisor, 6,123, you see that 6,123 cannot be had in 2,179; therefore take five places, and on the rods find a number that is equal, or next less to 21,797, which is 18,369: that is, three times the divisor, wherefore set 3 in the quotient, and subtract 18,369 from the figures above, and there will remain 3,428; to which add 8, the next figure of the dividend, and seek again on the rods for it, or the next less, which you will find to be five times; therefore set 5 in the quotient, and subtract 3,0615 from 34.228, and there will remain 3,673, to which add 8, the last figure in the dividend, and finding it to be just six times the divisor, set 6 in the quotient.

NEPETA, Catmint, or Nep, a genus of the gymnospermia order, in the didynamia class of plants; and in the natural method ranking under the 42d order, verticillatæ.—There are 20 species; the most remarkable is the *cataria*, common nep, or cat-mint. This is a native of many parts of Britain, growing about hedges, and in waste places. The plant has a bitter taste, and strong smell, not unlike pennyroyal.

NEPHRITE, in mineralogy, a species of the Talc genus; it is also called *jade*, or *jade-stone*. It was formerly celebrated for its medical virtues. It is of a dark leek-green colour, verging to blue. It occurs massive in detached rounded pieces. Nephrite is found in Egypt, China, America, the islands in the Pacific Ocean, and in the Siberian mountains sometimes adhering to rocks, and sometimes in detached round pieces. It is highly prized by the Hindoos and Chinese, by whom it is made into talismans and idols, and by the Turks, who form it into sword and dagger handles.

NEPHRITIC, something that relates to the kidneys.

NEREIS, in natural history, a genus of the vermes mollusca class and order. Body long, creeping, with numerous lateral peduncles or feet on each side; feelers simple; two or four eyes. There are about 30 species, in separate divisions. *N. noctiluca*, body blue-green, with 23 segments, hardly visible to the naked eye. These are found in most seas, and are highly phosphorous, giving a lucid splendour to the waves in the evening.

NERITA, a genus of vermes testacea: the generic character is; animal a limax; shell univalve, spiral, gibbous, flattish at bottom; aperture semiorbicular or semilunar; pillar-lip transversely truncate, flattish. There are about 80 species of this genus.

NERVES. See Anatomy.

NET, a device for catching fish and fowl. The making the nets is very easy, and what every true sportsman ought to be able to do for himself. All the necessary tools are wooden needles, of which there should be several of different sizes, some round and others flat: a pair of round-pointed and flat scissars, and a wheel to wind off the thread. The packthread is to be of different strength and thickness, according to the sort of birds to be taken; and the general size of the meshes, if not for very small birds, is two inches from point to point. The nets should neither be made too deep nor too long, for they are then difficult to manage; and they must be verged on each side with twisted thread.

NETTINGS, in a ship, a sort of grates made of small ropes, seized together with rope-yarn or twine, and fixed on the quarters and in the tops; they are sometimes stretched upon the ledges from the waste-trees to the roof-trees, from the top of the forecastle to the poop; and sometimes are laid in the waste of a ship to serve instead of gratings.

NETTLE. See Urtica.

NEUTRALIZATION. When acid and alkaline matter are combined in such proportions that the compound does not change the colour of litmus or violets, they are said to be neutralized.

NEWTONIAN PHILOSOPHY, the doctrine of the universe, or the properties, laws, affections, actions, forces motions, &c. of bodies, both celestial and terrestrial, as delivered by Newton.

The chief parts of the Newtonian philosophy, as delivered by the author, except his Optical Discoveries, &c. are contained in his Principia, or Mathematical Principles of Natural Philosophy. He founds his system on the following definitions.

1. Quantity of matter is the measure of the same, arising from its density and bulk con-

jointly. Thus, air of a double density, in the same space, is double in quantity; in a double space, is quadruple in quantity; in a triple space, is sextuple in quantity, &c.

2. Quantity of motion is the measure of the same, arising from the velocity and quantity of matter conjunctly. This is evident, because the motion of the whole is the motion of all its parts: and therefore in a body double in quantity, with equal velocity, the motion is double, &c.

3. The *vis insita, vis inertiæ*, or innate force of matter, is a power of resisting, by which every body, as much as in it lies, endeavours to persevere in its present state, whether it is of rest, or moving uniformly forward in a right line.

4. An impressed force is an action exerted upon a body, in order to change its state, whether of rest or motion. This force consists in the action only; and remains no longer in the body when the action is over.

5. A centripetal force is that by which bodies are drawn, impelled, or any way tend, towards a point, as to a centre. This may be considered of three kinds, absolute, accelerative, and motive.

6. The absolute quantity of a centripetal force is a measure of the same, proportional to the efficacy of the cause that urges it to the centre.

7. The accelerative quantity of a centripetal force, is the measure of the same, proportional to the velocity which it generates in a given time.

8. The motive quantity of a centripetal force, is a measure of the same, proportional to the motion which it generates in a given time. This is always known by the quantity of force equal and contrary to it, that is just sufficient to hinder the descent of the body.

After these definitions, follow certain scholia, treating of the nature and distinctions of time, space, place, and motion, absolute, relative, apparent, true, real, &c. After which, the author proposes to shew how we are to collect the true motions from their causes, effects, and apparent differences; and vice versa, how, from the motions, either true or apparent, we may come to the knowledge of their causes and effects. In order to this, he lays down the following axioms or laws of motion.

1st law. Every body perseveres in its state of rest, or of uniform motion in a right line, unless it is compelled to change that state by forces impressed upon it.

2d law. The alteration of motion is always proportional to the motive force impressed, and is made in the direction of the right line in which that force is impressed.

3d law. To every action there is always opposed an equal re-action; or the mutual actions of two bodies upon each other, are always equal, and directed to contrary parts. Thus, whatever draws or presses another, is as much drawn or pressed by that other.

From this axiom, or law, Newton deduces the following corollaries:

1. A body by two forces conjoined will describe the diagonal of a parallelogram, in the same time that it would describe the sides by those forces apart.

2. Hence is explained the composition of any one direct force out of any two oblique ones, viz. by making the two oblique forces the sides of a parallelogram, and the diagonal the direct one.

3. The quantity of motion, which is collected by taking the sum of the motions directed towards the same parts, and the difference of those that are directed to contrary parts, suffers no change from the action of bodies among themselves; because the motion which one body loses is communicated to another.

4. The common centre of gravity of two or more bodies does not alter its state of motion or rest by the actions of the bodies among themselves; and therefore the common centre of gravity of all bodies, acting upon each other, (excluding external actions and impediments) is either at rest, or moves uniformly in a right line.

5. The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forward in a right line without any circular motion. The truth of this is evident from the experiment of a ship; where all motions are just the same, whether the ship is at rest, or proceeds uniformly forward in a straight line.

6. If bodies, any how moved among themselves, are urged in the direction of parallel lines by equal accelerative forces, they will all continue to move among themselves, after the same manner as if they had not been urged by such forces.

The mathematical part of the Newtonian Philosophy depends chiefly on the following lemmas, especially the first, containing the doctrine of prime and ultimate ratios.

Lem. 1. Quantities, and the ratios of quantities, which in any finite time converge continually to equality, and before the end of that time approach nearer the one to the other than by any given difference, become ultimately equal.

Lem. 2 shews, that in a space bounded by two right lines and a curve, if an infinite number of parallelograms are inscribed, all of equal breadth; then the ultimate ratio of the curve space, and the sum of the parallelograms, will be a ratio of equality.

Lem. 3 shews that the same thing is true when the breadths of the parallelograms are unequal.

In the succeeding lemmas it is shewn, in like manner, that the ultimate ratios of the sine, chord, and tangent, of arcs infinitely diminished, are ratios of equality; and therefore that in all our reasonings about these, we may safely use the one for the other: that the ultimate form of evanescent triangles, made by the arc, chord, or tangent, is that of similitude, and their ultimate ratio is that of equality; and hence, in reasonings about ultimate ratios, these triangles may safely be used one for another, whether they are made with the sine, the arc, or the tangent. He then demonstrates some properties of the ordinates of curvilinear figures; and shews that the spaces which a body describes by any finite force urging it, whether that force is determined and immutable, or continually varied, are to each other, in the very beginning of the motion, in the duplicate ratio of

the forces; and lastly, having added some demonstrations concerning the evanescence of angles of contact, he proceeds to lay down the mathematical part of his system, which depends on the following theorems.

Theor. 1. The areas which revolving bodies describe by radii drawn to an immoveable centre of force, lie in the same immoveable planes, and are proportional to the times in which they are described.

Theor. 2. Every body that moves in any curve line described in a plane, and by a radius drawn to a point either immoveable or moving forward with an uniform rectilinear motion, describes about that point areas proportional to the times, is urged by a centripetal force directed to that point.

Theor. 3. Every body that by a radius drawn to the centre of another body, any how moved, describes areas about that centre proportional to the times, is urged by a force compounded of the centripetal forces tending to that other body, and of the whole accelerative force by which that other body is impelled.

Theor. 4. The centripetal forces of bodies which by equal motions describe different circles, tend to the centres of the same circles; and are one to the other as the squares of the arcs described in equal times, applied to the radii of circles.

On these and such like principles depends the Newtonian mathematical philosophy. The author farther shews how to find the centre to which the forces impelling any body are directed, having the velocity of the body given; and finds that the centrifugal force is always as the versed sine of the nascent arc directly, and as the square of the time inversely: or directly as the square of the velocity, and inversely as the chord of the nascent arc. From these premises, he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this, whether the central point is near hand, or at immense distance; so that all the lines drawn from it may be taken for parallels. And he shews the same thing with regard to bodies revolving in spirals, ellipses, hyberbolas, or parabolas.

He shews, also, having the figures of the orbits given, how to find the velocities and moving powers; and indeed resolves the most difficult problems relating to the celestial bodies with a surprising degree of mathematical skill.

In the second book, Newton treats of the properties and motion of fluids, and their powers of resistance, with the motion of bodies through such resisting mediums, those resistances being in the ratio of any powers of the velocities; and the motions being either made in right lines or curves, or vibrating like pendulums.

The third book is occupied in demonstrating the frame of the system of the world; and the phenomena first considered are the following.

1. That the satellites of Jupiter, by radii drawn to his centre, describe areas proportional to the times of description; and that their periodic times, the fixed stars being at rest, are in the sesquiplicate ratio of their distances from that centre. 2. The same thing is likewise observed of the phenomena of Saturn. 3. The five primary planets, Mercury, Venus, Mars, Jupiter, Saturn with their several orbits, encompass the sun. 4. The fixed stars being supposed at rest, the periodic times of the said five primary planets, and of the earth, about the sun, are in the sesquiplicate proportion of their mean distances from the sun. 5. The primary planets, by radii drawn to the earth, describe areas no ways proportional to the times; but the areas which they describe by radii drawn to the sun are proportional to the times of description. 6. The moon, by a radius drawn to the centre of the earth, describes an area proportional to the time of description. All which phenomena are clearly evinced by astronomical observations. The mathematical demonstrations are next applied by Newton in the following propositions.

Prop. 1. The forces by which the satellites of Jupiter are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the centre of that planet, and are reciprocally as the squares of the distances of those satellites from that centre.

Prop. 2. The same thing is true of the primary planets, with respect to the sun's centre.

Prop. 3. The same thing is also true of the moon, in respect of the earth's centre.

Prop. 4. The moon gravitates towards the earth; and by the force of gravity is continually drawn off from a rectilinear motion, and retained in her orbit.

Prop. 5. The same thing is true of all the other planets, both primary and secondary, each with respect to the centre of its motion.

Prop. 6. All bodies gravitate towards every planet; and the weights of bodies towards any one and the same planet, at equal distances from its centre, are proportional to the quantities of matter they contain.

Prop. 7. There is a power of gravity tending to all bodies proportional to the several quantities of matter which they contain.

Prop. 8. In two spheres mutually gravitating each towards the other, if the matter in places on all sides, round about, and equidistant from the centres, is similar, the weight of either sphere towards the other, will be reciprocally as the square of the distance between their centres. Hence are compared together the weights of bodies towards different planets; hence also are discovered the quantities of matter in the several planets; and hence likewise are found the densities from those planets.

Prop. 9. The force of gravity, in parts downwards from the surface of the planets towards their centres, decreases nearly in the proportion of the distances from those centres.

These, and many other proportions and corollaries, are proved or illustrated by a great variety of experiments, in all the great points of physical astronomy.

NICKLE. See Chemistry.

NICOTIANA. See Tobacco.

NICTITATING *membrane,* in comparative anatomy, a thin membrane, chiefly found in the bird and fish-kind, which covers the eyes of these animals, sheltering them

from the dust or from too much light; yet is so thin and pellucid, that they can see pretty well through it.

NIDUS, among naturalists, signifies a nest, or proper repository for the eggs of birds, insects, &c. wherein the young of these animals are hatched and nursed.

NIGHT, that part of the natural day during which the sun is underneath the horizon; or that space wherein it is dusky. Night was originally divided by the Hebrews, and other eastern nations, into three parts, or watchings. The Romans, and afterwards the Jews from them, divided the night into four parts, or watches, the first of which began at sun-set and lasted till nine at night, according to our way of reckoning; the second lasted till midnight; the third till three in the morning; and the fourth ended at sun-rise. The ancient Gauls and Germans divided their time not by days but by nights; and the people of Iceland and the Arabs do the same at this day. The like is also observed of our Saxon ancestors.

NIGHT-MARE. See MEDICINE.

NIGHTINGALE. See MOTACILLA.

NIHIL DICIT, a failure in the defendant to put in an answer to the plaintiff's declaration, &c. by the day assigned for that purpose, by which omission judgment of course is had against him.

NIMBUS, in antiquity, a circle observed on certain medals, or round the head of some emperors, answering to the circles of light drawn around the images of saints.

NINTH, in music, an interval containing an octave and a tone; also a name given to the chord consisting of a common chord with the eighth advanced one note.

NIPA, a genus of the natural order of palms. The male has a spathe; the corolla is six-petalled. The female has a spathe; corolla none; drupes angular. There is one species, a native of the E. Indies. The leaves are used in making mats.

NIPPLES, in anatomy. See MAMMARY GLAND.

NISI PRIUS, in law, a commission directed to the judges of assize, empowering them to try all questions of fact issuing out of the courts at Westminster that are then ready for trial by jury. The original of which name is this: all causes commenced in the courts of Westminster-hall are, by course of the courts, appointed to be tried on a day fixed in some Easter or Michaelmas term, by a jury returned from the county wherein the cause of action arises; but with this proviso, nisi prius justiciarii ad assisas capiendas venerint: that is, unless before the day prefixed, the judges of assize come into the county in question, which they always do in the vacation preceding each Eastern and Michaelmas term, and there try the cause. And then upon the return of the verdict given by the jury to the court above, the judges there give judgment for the party for whom the verdict is found.

NITRATES, are salts formed of nitric acid, with the salifiable bases.

NITRE, commonly known by the name of *saltpetre*, is found ready formed in the East Indies, in Spain, in the kingdom of Naples, and elsewhere, in considerable quantities; but nitrate of lime is still more abundant. For the greater part of the nitre made use of is produced by a combination of circumstances which tend to compose and condense nitric acid. This acid appears to be produced in all situations, where animal matters are completely decomposed with access of air, and of proper substances with which it can readily combine. Grounds frequently trodden by cattle, and impregnated with their excrements, or the walls of inhabited places, where putrid animal vapours abound, such as slaughter-houses, drains, or the like, afford nitre by long exposure to the air.

Artificial nitre beds are made by an attention to the circumstances in which this salt is produced by nature. Dry ditches are dug, and covered with sheds, open at the sides, to keep off the rain: these are filled with animal substances—such as dung, or other excrements, with the remains of vegetables, and old mortar, or other loose calcareous earth; this substance being found to be the best and most convenient receptacle for the acid to combine with. Occasional watering, and turning up from time to time, are necessary to accelerate the process, and increase the surfaces to which the air may apply; but too much moisture is hurtful.

If the beds contain much vegetable matter, a considerable proportion of the nitrous salt will be common saltpetre; but if otherwise, the acid will, for the most part, be combined with the calcareous earth. It consists of 6.75 acid + 6 potash.

To extract the saltpetre from the mass of earthy matter, a number of large casks are prepared with a cock at the bottom of each, and a quantity of straw within, to prevent its being stopped up. Into these the matter is put, together with wood-ashes, either strewed at top, or added during the filling. Boiling water is then poured on, and suffered to stand for sometime; after which it is drawn off, and other water added in the same manner, as long as any saline matter can be thus extracted.

The crystals of nitre are usually of the form of six-sided flattened prisms, with diedral summits. Its taste is penetrating; but the cold produced by placing the salt to dissolve in the mouth, is such as to predominate over the real taste at first. Seven parts of water dissolve two of nitre, at the temperature of sixty degrees; but boiling water dissolves its own weight. 100 parts of alcohol, at a heat of 176°, dissolve only 2.9.

On being exposed to a gentle heat, nitre fuses; and in this state being poured into moulds, so as to form little round cakes, or balls, it is called *sal prunella*, or *crystal mineral*.

This salt powerfully promotes the combustion of inflammable substances. Two or three parts mixed with one of charcoal, and set on fire, burn rapidly; azote and carbonic acid gas are given off, and a small portion of the latter is retained by the alkaline residuum, which was formerly called *clyssus of nitre*. Three parts of nitre, two of subcarbonate of potash, and one of sulphur, mixed together in a warm mortar, form the *fulminating power:* a small quantity of which, laid on a fire shovel, and held over the fire

till it begins to melt, explodes with a loud sharp noise. Mixed with sulphur and charcoal it forms *gunpowder*

The uses of nitre are various. Besides those already indicated, it enters into the composition of fluxes, and is extensively employed in metallurgy; it serves to promote the combustion of sulphur in fabricating its acid; it is used in the art of dyeing; it is added to common salt for preserving meat, to which it gives a red hue; it is an ingredient in some frigorific mixtures; and it is prescribed in medicine, as cooling, febrifugal, and diuretic; and some have recommended it mixed with vinegar, as a very powerful remedy for the sea scurvy.

NITRIC-ACID. The two principal constituent parts of our atmosphere, when in certain proportions, are capable, under particular circumstances, of combining chemically into one of the most powerful acids, the nitric. If these gasses be mixed in a proper proportion in a glass tube about a line in diameter, over mercury, and a series of electric shocks be passed through them for some hours, they will form nitric acid; or if a solution of potash be present with them, nitrate of potash will be obtained. The constitution of this acid may be further proved, analytically, by driving it through a red-hot porcelain tube, as thus it will be decomposed into oxygen and nitrogen gases. For all practical purposes, however, the nitric acid is obtained from nitrate of potash, from which it is expelled by sulphuric acid.

The nitric acid is of considerable use in the arts. It is employed for etching on copper; as a solvent of tin to form with that metal a mordant for some of the finest dyes; in metallurgy and assaying; in various chemical processes, on account of the facility with which it parts with oxygen and dissolves metals; in medicine as a tonic, and as a substitute for mercurial preparations in siphylis and affections of the liver, as also in form of vapour to destroy contagion. For the purposes of the arts it is commonly used in a diluted state, and contaminated with the sulphuric and muriatic acids, by the name of *aquafortis.* This is generally prepared by mixing common nitre with an equal weight of sulphate of iron, and half its weight of the same sulphate calcined, and distilling the mixture; or by mixing nitre with twice its weight of dry powdered clay, and distilling in a reverberatory furnace. Two kinds are found in the shops, one called *double aquafortis,* which is about half the strength of nitric acid; the other simply *aquafortis,* which is half the strength of the double.

A compound made by mixing two parts of the nitric acid with one of muriatic, known formerly by the name of *aqua regia*, and now by that of *nitro-muriatic acid,* has the property of dissolving gold and platina. On mixing the two acids, heat is given out, an effervescence takes place, and the mixture acquires an orange colour. *Aqua regia* does not oxidize gold and platina. It merely causes their combination with chlorine.

With the different bases the nitric acid forms nitrates. The nitrate of barytes, when perfectly pure, is in regular octaedral crystals, though it is sometimes obtained in small shining scales. It may be prepared by uniting barytes directly with nitric acid, or by decomposing the carbonate or sulphuret of barytes with this acid. Nitrate of strontian may be obtained in the same manner as that of barytes, with which it agrees in the shape of its crystals, and most of its properties. Applied to the wick of a candle, or added to burning alcohol, it gives a deep red colour to the flame. On this account it may be useful, perhaps, in the art of pyrotechny. Nitrate of lime, the *calcareous nitre* of older writers, abounds in the mortar of old buildings, particularly those that have been much exposed to animal effluvia, or processes in which azote is set free The nitrate of ammonia possesses the property of exploding, and being totally decomposed, at the temperature of 600°; whence it acquired the name of *nitrum flammans.* The readiest mode of preparing it is by adding carbonate of ammonia to dilute nitric acid till saturation takes place.

NITROGEN, called also AZOTE, is an important elementary or undecomposed principle. As it constitutes four-fifths of the volume of atmospheric air, the readiest mode of procuring azote is to abstract its oxygenous associate, by the combustion of phosphorus or hydrogen. It may also be obtained from animal matter, subjected in a glass retort to the action of nitric acid, diluted with 8 or 10 times its weight of water.

Azote possesses all the physical properties of air. It extinguishes flame and animal life. It is absorbable by about 100 volumes of water. Its spec. gravity is 0.9722. 100 cubic inches weight 29.65 grains. It has neither taste nor smell. It unites with oxygen in four proportions, forming four important compounds. These are,

1 Protoxide of azote, or nitrous oxide.

2. Deutoxide of azote, nitrous gas, or nitric oxide.

3. Nitrous acid.

4. Nitric acid.

Nitrous oxide or *protoxide of azote,* was discovered by Dr. Priestley in 1772, but was first accurately investigated by Sir H. Davy in 1799. The best mode of procuring it, is to expose the salt called nitrate of ammonia, to the flame of an Argand lamp, in a glass retort. When the temperature reaches 400° F. a whitish cloud will begin to project itself into the neck of the retort, accompanied by the copious evolution of gas, which must be collected over mercury for accurate researches, but for common experiments may be received over water. It has all the physical properties of air. It has a sweet taste a faint agreeable odour, and is condensable by about its own volume of water, previously deprived of its atmospheric air. This property enables us to determine the purity of nitrous oxide. A taper plunged into this gas burns with great brilliancy; the flame being surrounded with a bluish halo. But phosphorus may be melted and sublimed in it, without taking fire. When this combustible is introduced into it, in a state of vivid combustion, the brilliancy of the flame is greatly increased. Sulphur and most other combustible bodies require a higher degree of heat for their combustion in it, than in either oxygen or common air. This may be

intimately combined with azote. Its sp. grav. is 1.5277. 100 cubic inches weigh 46.6 gr. It is respirable, but not fitted to support life. Sir H. Davy first shewed, that by breathing a few quarts of it, contained in a silk bag, for two or three minutes, effects analogous to those occasioned by drinking fermented liquors were produced. Individuals, who differ in temperament, are, however, as we might expect, differently affected.

Among others who have tried the effect of this gas on the nervous system, we have the name of Robert Southey. We are not acquainted with the exact time at which the poet inhaled the pleasing draught, but the effect produced was rather ominous, viz—*Giddiness*, the effect of *elevation*, and the fear of *falling*. The following is his own account of the matter:

Mr. Robert Southey could not distinguish between the first effects and an apprehension of which he was unable to divest himself. His first definite sensations were, a fulness and dizziness in the head, such as to induce a fear of falling. This was succeeded by a laugh which was involuntary, but highly pleasurable, accompanied with a peculiar thrilling in the extremities; a sensation perfectly new and delightful. For many hours after this experiment, he imagined that his taste and smell were more acute, and is certain that he felt unusually strong, and cheerful. In a second experiment, he felt pleasure still superior, and has once poetically remarked, that he supposes the atmosphere of the highest of all possible heavens to be composed of this gas.

This gas is frequently given by public lecturers to some of their audience for inhalation, in order to afford amusement to the company; but much caution ought to be observed on this head, as it has been known to prove fatal, where there was a tendency of blood to the head.

NOBILITY, a quality that ennables, and raises a person possessed of it above the rank of a commoner.

The civil state of England consists of the nobility and commonalty. The nobility are all those who are above the degree of knight, under which term is included that of a baronet; namely, dukes, marquises, earls, viscounts and barons.

NOBLE, a money of account containing six shillings and eight-pence. The noble was anciently a real coin struck in the reign of Edward III. and then called the penny of gold; but it was afterwards called a rose noble, from its being stamped with a rose.

NOCTURNAL, something relating to the night, in contradistinction to diurnal.

NOCTURNAL *arch*, in astronomy, the arch of a circle described by the sun, or a star, in the night.

NOCTURNAL, *semi, arch of the sun*, is that portion of a circle he passes over between the lower part of our meridian and the point of the horizon, wherein he arises; or between the point of the horizon wherein he sets, and the lower part of our meridian.

NOCTURNAL, NOCTURLABIUM, an instrument chiefly used at sea, to take the altitude or depression of some stars about the pole, in order to find the latitude, and hour of the night.

Some nocturnals are hemispheres, or planispheres on the plane of the equinoctial. Those commonly in use among seamen are two; the one adapted to the polar star, and the first of the guards of the little bear; the other to the pole-star, and the pointers of the great bear.

This instrument consists of two circular plates applied to each other. The greater, which has a handle to hold the instrument, is about two inches and a half diameter, and is divided into twelve parts, agreeing to the twelve months, and each month subdivided into every fifth day; and so as that the middle of the handle corresponds to that day of the year wherein the star here regarded has the same right ascension with the sun. If the instrument be fitted for two stars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour sub-divided into quarters. These twenty-four hours are noted by twenty-four teeth to be told in the night. Those at the hours twelve, are distinguished by their length. In the centre of the two circular plates is adjusted a long index, moveable upon the upper plate. And the three pieces, *viz.* the two circles and index, are joined by a rivet which is pierced through the centre with a hole, through which the star is to be observed.

"To use the Nocturnal," turn the upper plate till the long tooth, marked twelve, be against the day of the month on the under plate: then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial; and viewing the pole-star through the hole of the centre, turn the index about till, by the edge coming from the centre, you see the bright star or guard of the little bear (if the instrument be fitted to that star:) then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour circle: which may be known without a light, by counting the teeth from the longest, which is for the hour twelve.

NODE, in surgery, a tumor arising on the bones, and usually proceeding from some venereal cause.

NODES, in astronomy, the two points wherein the orbit of a planet intersects the ecliptic, whereof the node, where the planet ascends northwards, above the plane of the ecliptic, is called the ascending node, the northward node, and the head of the Dragon, and is marked thus ☊; the other node, where the plane descends to the south, is called the descending node, the southward node, or the Dragon's tail, marked thus ☋.

The line wherein the two circles intersect, is called the line of nodes. It appears from observation, that the line of the nodes of all the planets constantly changes its place, and shifts its situation from east to west, contrary to the order of the signs; and that the line of the Moon's nodes, by a retrograde motion, finishes its circulation in the compass of nineteen years; after which time, either of the nodes having receded from any point of the ecliptic, returns to the same again; and when the

Moon is in the node, she is also seen in the ecliptic.

NO-MAN'S-LAND, a space in midships, between the after-part of the belfry and the forepart of a boat, when she is stowed upon the booms, as in a deep waisted vessel.

NOMENCLATURE, a catalogue of several of the more usual words in any language, with their significations, compiled in order to facilitate the use of such words, to those who are to learn the tongue: such are our Latin, Greek, French, &c. nomenclatures.

NOMINATIVE, in grammar, the first case of nouns which are declinable.

NONAGISMAL, in astronomy, the 90th degree of the ecliptic, reckoned from the eastern term, or point. The altitude of the nonagesimal is equal to the angle of the east, and, if continued, passes through the poles of the ecliptic; whence the altitude of the nonagesimal at a given time, under a given elevation of the pole, is easily found.

NON-APPEARANCE, a default in not appearing in a court of judicature. Attorneys subscribing warrants for appearing in court are liable to attachment and fine for non-appearance. If a defendant does not appear and find bail upon a scire facias and rule given, judgment may be had against him.

NON-COMPOS-MENTIS, in law, is used to denote a person's not being of sound memory and understanding. Of these persons there are four different kinds: an idiot, a madman, a lunatic, who has lucid intervals, and a drunkard who deprives himself of reason by his own act and deed.

NONES, *nonæ*, in the Roman calendar, the fifth day of the months January, February, April, June, August, September, November, and December; and the seventh of March, July, and October. March, May, July, and October, had six days in their nones; because these alone, in the ancient constitution of the year by Numa, had 31 days each, the rest having only 29, and February 30; but when Cæsar reformed the year, and made other months containing 31 days, he did not allot them six days of nones.

NONIUS. See Vernier.

NONSUIT, in law, is where a person has commenced an action, and at the trial fails in his evidence to support it, or has brought a wrong action. There is this advantage attending a nonsuit, that the plaintiff, though he pays costs, may afterwards bring another action for the same cause, which he cannot do after a verdict against him.

NORMAL, in geometry, signifies the same with a perpendicular, and is used for a line or plane that intersects another perpendicularly.

NOSE, the primary organ of smelling. See Anatomy.

NOSTOCK, the name of a vegetable substance which seems to differ from almost all others of the same kind. It is of a greenish colour, partly transparent, and of a very irregular figure. It trembles at the touch like jelly, but does not melt like that. It is found in all sorts of soils, but most frequently in sandy ones, sometimes on the gravel of garden walks, usually after rain in the summer months.

NOTARY, is a person duly appointed to attest deeds and writings; he also protests and notes foreign and inland bills of exchange, and promissory notes, translates languages, and attests the same, enters and extends ship's protests, &c.

NOTATION, in arithmetic and algebra, the method of expressing numbers or quantities by signs or characters, appropriated for that purpose.

Notation, in music, the manner of expressing, or representing by characters, all the different sounds used in music.

NOTE is a minute, or short writing, containing some article of business; in which sense we say, promissory note, note of hand, bank note. See Bills of Exchange.

NOTES, in music, characters which by their various forms and situations on the staves, indicate the duration as well as the gravity or acuteness of the several sounds of a composition.

NOTICE in law, is the making something known that a man was or might be ignorant of before, and it produces divers effects.

NOT GUILTY, is the general issue or plea of the defendant in any criminal action or prosecution; as also in an action of trespass, or upon the case for deceits and wrongs; but not on a promise or assumpsit.

NOUN, in grammar, a part of speech, which signifies things without any relation to time: as a man, a house, sweet, bitter, &c.

NUCLEUS, in general, denotes the kernel of a nut, or even any seed inclosed within a husk. The term nucleus is also used for the body of a comet, otherwise called its head.

NOVEL, in the civil law, a term used for the constitutions of several emperors, as of Justin, Tiberius, Leo, and more particularly for those of Justinian.

Novel *assignment*, or new assignment, a term in law pleadings which it is difficult to explain to those unacquainted with practical pleading. It occurs in actions of trespass, where the form of the declaration being very general, the defendant pleads in bar a common justification; to which the plaintiff replies by stating, that he brought his action as well for a certain other trespass which he states with more particularity, as for that which is justified. This is called a new assignment.

NOVEMBER, in chronology, the 11th month of the Julian year, consisting only of thirty days; it got the name of November, as being the ninth month of Romulus's year, which began with March.

NUDE *contract, nudum pactum*, a bare promise without any consideration, and not authenticated by deed, which is therefore void in law.

NUISANCE, signifies generally any thing that does hurt, inconvenience, or damage to the property or person of another. Nuisances are of two kinds, public and private, and either affect the public or the individual. The remedy for a private nuisance is by action on the case for damages, and for a public nuisance by indictment. Amongst the nuisances which most commonly occur are the erecting of

noxious manufactures in towns, and in the vicinity of ancient houses; such as the erecting a vitriol manufactory, to the annoyance of the neighbours in general. Disorderly houses, bawdy-houses, stage booths, lotteries, and common scolds, are also public nuisances. Where the injury is merely to an individual, and not to the public, the individual only has an action; but not in the case of a public nuisance, where the private injury is merged, or lost, in that of the public, but where an individual receives a particular injury by a public nuisance. And any one aggrieved may abate, that is, pull down and remove a nuisance, after which he can have no action: but this is a dangerous attempt to take the law into one's own hands. It must be done without riot, if at all. Every continuance of a nuisance is a fresh nuisance, and a fresh action will lie.

NUMBER, a collection of several units, or of several things of the same kind, as 2, 3, 4, &c. Number is unlimited in respect of increase; but in respect of decrease it is limited; unity being the first and least number.

NUMBERS, *kinds and distinctions of.* Mathematicians, considering number under a great many relations, have established the following distinctions. Broken numbers are the same with fractions. See ARITHMETIC. Cardinal numbers, are those which express the quantity of units, as 1, 2, 3, 4, &c. whereas ordinal numbers are those which express order, as 1st, 2d, 3d, &c. Compound number, one divisible by some other number besides unity; as 12, which is divisible by 2, 3, 4, and 6. Numbers, as 12 and 15, which have some common measure besides unity, are said to be compound numbers among themselves. Cubic number, is the product of a square number by its root: such is 27, as being the product of the square number 9, by its root 3.

Determinate number, is that referred to some given unit, as a ternary or three: whereas an indeterminate one, is that referred to unity in general, and is called quantity. Homogeneal numbers, are those referred to the same unit; as those referred to different units are termed heterogeneal. Whole numbers are otherwise called integers. Rational number, is one commensurable with unity; as a number, incommensurable with unity, is termed irrational or a surd. In the same manner a rational whole number is that whereof unity is an aliquot part; a rational broken number, that equal to some aliquot part of unity; and a rational mixed number, that consisting of a whole number and a broken one. Even number, that which may be divided into two equal parts without any fraction, as 6, 12, &c. An evenly even number, is that which may be measured, or divided, without any remainder, by another even number, as 4 by 2. An unevenly even number, when a number may be equally divided by an uneven number, as 20 by 5. Uneven number, that which exceeds an even number, at least by unity, or which cannot be divided into two equal parts, 3, 5, &c. Primitive, or prime numbers, are those only divisible by unity. Prime numbers among themselves, are those which have no common measure besides unity. Perfect number, that whose aliquot parts added together make the whole number. Imperfect numbers, those whose aliquot parts, added together, make either more or less than the whole. These are distinguished into abundant and defective; an instance in the former case, is 12, whose aliquot parts 6, 4, 3, 2, 1, make 16; and in the latter case 16, whose aliquot parts 8, 4, 2, and 1, make but 15. Plain number, that arising from the multiplication of two numbers, as 6, which is the product of 3 by 2; and these numbers are called the sides of the plane. Square number, is the product of any number multiplied by itself: thus 4, which is the factum of 2 by 2, is a square number Polygonal, or polygonous numbers, the sums of arithmetical progressions beginning with unity; these, where the common difference is, 1, are called triangular numbers; where 2, square numbers; where 3, pentagonal numbers; where 4, hexagonal numbers; where 5, heptagonal numbers, &c. Pyramidal numbers, the sums of polygonous numbers, collected after the same manner as the polygons themselves, and not gathered out of arithmetical progressions, are called first pyramidal numbers: the sums of the first pyramidals are called second pyramidals, &c. If they arise out of triangular numbers, they are called triangular pyramidal numbers; if out of pentagons, first pentagonal pyramidals. From the manner of summing up polygonal numbers, it is easy to conceive how the prime pyramidal numbers are found, viz.

$\frac{(a-2)n^3+3n^2-(a-5)n}{6}$ expresses all the prime pyramidals.

NUMBER, in grammar, a modification of nouns, verbs, &c. to accommodate them to the varieties in their objects, considered with regard to number.

NUMBERS, in poetry, oratory, music, &c. are certain measures, proportions, or cadences, which render a verse, period, or song, agree able to the ear.

NUMERAL *letters,* those letters of the alphabet which are generally used for figures, as I, V, X, L, C, D, M.

NUMERATION, or NOTATION, the art of expressing in characters any number proposed in words; or of expressing in words any number proposed in characters.

NUMERICAL, or NUMERAL, something belonging to numbers, as numerical algebra is that which makes use of numbers instead of letters of the alphabet.

NUMIDIA, the *Pintado,* or *guinea-hen,* in natural history, a genus of birds of the order gallinæ. Bill strong and short, with a carunculate cere at the base, in which the nostrils are lodged; head horned with a compressed coloured callus; wattels hanging from the cheeks; tail short, and pointing downwards; body speckled. There are four species. *N. meleagris,* is of the size of a very large fowl. Its native territory is Africa. It is gregarious, having been often seen in very numerous flocks. It is now extremely common in this country. The female lays many eggs, and secreting her nest, sometimes will suddenly appear with a family of twenty young ones. It is a bird of harsh sound, and almost perpetually uttering it. The flesh of the young birds is valued, and its eggs are thought preferable to those of the common hen.

NUNCIO or NUNTIO, an ambassador from

the pope to some catholic prince or state; or a person who attends on the pope's behalf at a congress, or an assembly of several ambassadors.

NUNCUPATIVE will, denotes a last will or testament, only made verbally, and not put in writing. See WILL and TESTAMENT.

NURSERY, is a piece of land set apart for raising and propagating trees and plants, to supply the garden and other plantations.

In a nursery for fruit trees, the following rules are to be observed, 1. That the soil should not be better than that in which the trees are to be planted out. 2. That it ought to be fresh. 3. It ought neither to be too wet, nor too dry, but rather of a middling nature, though of the two extremes, dry is to be preferred. 4. It must be inclosed in such a manner, that neither cattle nor vermin may come in; and so as particularly to exclude hares and rabbits. 5. The ground being inclosed, should be carefully trenched about two feet deep, in August. In trenching the ground, cleanse it from the roots of all noxious weeds. 6. The season being come for planting, level down the trenches about the beginning of October, and then lay out the ground into quarters, which may be laid out in beds for a seminary, in which you may sow the seeds or stones of fruit. 7. And having provided yourself with stocks, the next year proceed to transplant them: draw a line across the ground, and open a number of trenches exactly straight; then take the stocks out of the seed-beds; in doing which, you should raise the ground with a spade, in order to preserve the roots as entire as possible; prune off the very small fibres, and if there are any that have a tendency to root directly downwards, such roots should be shortened. Then plant them in the trenches, if they are designed for standards, in rows three feet and a half, or four feet, from each other, and a foot and a half distant in the rows; but if for dwarfs, three feet row from row, and one foot in the row, will be a sufficient distance. These plants should not be headed or pruned at top. If the winter should prove very cold, lay some muck on the surface of the ground near their roots, taking care not to let it lie too thick near the stems of the plants, and to remove it as soon as the frost is over. In the summer season destroy the weeds, and dig up the ground every spring between the rows. See GRAFTING.

As to timber trees, nurseries should be made upon the ground intended for planting, where a sufficient number of the trees may be left standing, after the others have been drawn out to plant in other places.

NUTATION, in astronomy, a kind of tremulous motion of the axis of the earth, whereby in each annual revolution it is twice inclined to the ecliptic, and as often returns to its former position.

NUT-GALLS are excrescences formed on leaves of the oak by the puncture of an insect which deposits an egg on them. The best are known by the name of Aleppo-galls, imported for the use of dyers, calico-printers, &c. See GALLIC ACID and TANNIN.

NUTMEG, the kernel of a large fruit, not unlike the peach, the produce of the MYRISTICA, which see.

The nutmeg is separated from its investient coat, the mace, before it is sent over to us. See MACE.

NUX *vomica*, a flat, compressed, round fruit, about the breadth of a shilling, brought from the East Indies. It is found to be a certain poison for dogs, cats, &c. For a more particular account of the nature of this poison, see the article STRYCHNIA.

NYMPH, among naturalists, that state of winged insects, between their living in the form of a worm, and their appearing in the winged or most perfect state. See ENTOMOLOGY.

NYMPHÆ, are two membranaceous parts, situated on each side the rima. They are of a red colour, and cavernous structure; they vary much in size in different persons; they are contiguous to the præputium of the clitoris, and joined to the interior side of the labia.

NYMPHÆA, the *water-lily*, a genus of the monogynia order, in the polyandria class of plants; and in the natural method ranking under the 54th order, miscellanea. The corolla is polypetalous; the calyx tetraphyllous or pentaphyllous: the berry multilocular and truncated. There are six species, of which the most remarkable are: 1 and 2. The *lutea* and *alba*, or yellow and white water lilies; both of which are natives of Britain, growing in lakes and ditches. Linnæus tells us, that swine are fond of the leaves and roots of the former; and that the smoke of it will drive away crickets and blattæ, or cock-roaches, out of houses. The root of the second has an astringent and bitter taste, like those of most aquatic plants that run deep into the mud. 3. The lotus, with heart-shaped toothed leaves, a plant thought to be peculiar to Egypt, is mentioned by Herodotus. M. Savary mentions it as growing in the rivulets and on the sides of the lakes; and that there are two sorts or varieties of the plant, the one with a white, the other with a blueish flower. The calyx blows like a large tulip, and diffuses a sweet smell, resembling that of the lily. The first species produces a round root like that of a potatoe; and the inhabitants of the banks of the lake Menzall feed upon it. The rivulets in the environs of Damietta are covered with this majestic flower, which rises upwards of two feet above the water. 4. In the East and West Indies grows a species of this plant, named nelumbo by the inhabitants of Ceylon. The flowers are large, flesh-coloured, and consist of numerous petals, disposed as in the other species of water-lily, in two or more rows. The seed vessel is shaped like a top, being broad and circular above, narrow and almost pointed below. It is divided into several distinct cells, which form so many large round holes upon the surface of the fruit, each containing a single seed. With the flower of this plant, which is sacred among the heathens, they adorn the altars of their temples. The stalks, which are used as a pot-herb, are of a wonderful length.

NYSSA, a genus of the order of diœcia, in the polygamia class of plants; and in the natural method ranking under the 12th order, holoraceæ. There are two species: 1. The integrifolia, entire-leaved; and, 2. The denticulata, or serrated-leaved tupelo.

O.

O, the fourteenth letter of our alphabet. As a numeral, it is sometimes used for eleven; and with a dash over it thus Ō for eleven thousand. In the notes of the ancients, O. CON. is read opus conductum; O. C. Q. opere consilioque; O. D. M. opera, donum, munus; and O. L. O. opus locatum.

In music, the O, or rather a circle, or double CO, is a note of time called by us a semi-breve; and by the Italians circolo. The O is also used as a mark of triple time, as being the most perfect of all figures.

OAK. See QUERCUS.

OAKAM, old ropes untwisted, and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

OAR, in navigation, a long piece of wood, for moving a vessel by rowing. Oars for ships are generally cut out of fir timber, those for barges are made out of New England or Dantzic rafters, and those for boats, either out of English ash, or fir-rafters from Norway.

OAT. See AVENA.

OATH, an affirmation or denial of any thing before one or more persons, who have the authority to administer the same, for the discovery and advancement of truth and right. See AFFIDAVIT.

OBELISK, a truncated, quandrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics.

OBJECT, in philosophy, something apprehended, or presented to the mind, by sensation or by imagination.

OBJECT *glass of a telescope, or microscope*, the glass placed at the end of the tube which is next the object.

OBLATE, flatted, or shortened; as an oblate spheroid, having its axis shorter than its middle diameter, being formed by the rotation of an ellipse about the shorter axis.

OBLATENESS. See EARTH, *figure of*.

OBLIGATION, a bond containing a penalty, with a condition annexed, either for payment of money, performance of covenants, or the like. This security is called a specialty. Co. Lit. 172. See BOND, and DEED.

OBLIQUE, in geometry, something aslant, or that deviates from the perpendicular. Thus, an oblique angle, is either an acute or obtuse one; that is, any angle except a right one.

OBLIQUE PLANES. See DIALLING.

OBLONGATA MEDULLA. See ANATOMY.

OBOLUS, in antiquity, an ancient Athenian coin, worth a penny farthing. Among ancient physicians, obolus likewise denoted a weight, equal to ten grains.

OBOLARIA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The calyx is bifid; the corolla campanulated and quadrifid; the capsule unilocular, bivalved, and polyspermous; the stamina rising from the divisions of the corolla. There is one species, a herb of Virginia.

OBSERVATORY, a place destined for observing the heavenly bodies; being generally a building erected on some eminence, covered with a terrace for making astronomical observations.

The principal instruments for a fixed observatory are, a large fixed quadrant, or a circular divided instrument, chiefly for measuring vertical angles; a transit instrument; an equatorial instrument; a chronometer, or regulator; one or more powerful telescopes; a fixed zenith telescope, and a night telescope.

The quadrant, or quarter of a circle, divided into 90°, and each degree subdivided into minutes or smaller parts, has been made of various sizes; some of them having a radius even of eight or nine or more feet in length. When those quadrants do not exceed one or two, or at most three feet, in radius, they are generally fixed upon their particular stands, which are furnished with various mechanical contrivances, that are necessary to place the plane of the quadrant perpendicular to the horizon, and for all the other necessary adjustments. But large quadrants are fixed upon a strong wall.

The transit instrument consists of a telescope of any convenient length, fixed at right angles to a horizontal axis, which axis is supported at its two extremities; and the instrument is generally situated so that the line of collimation of the telescope may move in the plane of the meridian. The use of this instrument is to observe the precise time of the celestial bodies' passage across the meridian of the observatory.

To adjust the clock by the sun's transit over the meridian.—Note the times by the clock when the preceding and following edges of the sun's limb touch the cross wires. The difference between the middle time and 12 hours, shews how much the mean, or time by the clock, is faster or slower than the apparent, or solar time, for that day; to which the equation of time being applied, will show the time of mean noon for that day, by which the clock may be adjusted.

Astronomical or equatorial sector, an instrument for finding the difference in right ascension and declination between two objects, the distance of which is too great to be observed by the micrometer, was invented by Graham.

Equatorial or portable observatory: an instrument designed to answer a number of useful purposes in practical astronomy, independently of any particular observatory; it may be made use of in any steady room, and performs most of the useful problems in the science.

The principal uses of this equatorial are,

1. To find the meridian by one observation only: for this purpose elevate the equatorial circle to the co-latitude of the place, and set the declination-semicircle to the sun's declination for the day and hour of the day required; then move the azimuth and hour-circles both at the same time, either in the same or contrary directions, till you bring the centre of the cross hairs in the telescope exactly to

cover the centre of the sun; when that is done, the index of the hour-circle will give the apparent or solar time at the instant of observation; and thus the time is gained, though the sun is at a distance from the meridian; then turn the hour-circle till the index points precisely at 12 o'clock, and lower the telescope to the horizon, in order to observe some point there in the centre of your glass, and that point is your meridian mark found by one observation only: the best time for this operation is three hours before or three hours after 12 at noon.

2. To point the telescope on a star, though not on the meridian, in full day-light. Having elevated the equatorial circle to the co-latitude of the place, and set the declination-semicircle to the star's declination, move the index of the hour-circle till it shall point to the precise time at which the star is then distant from the meridian, found in tables of the right ascension of the stars, and the star will then appear in the glass. Besides these uses peculiar to this instrument, it is also applicable to all the purposes to which the principal astronomical instruments, viz. a transit, a quadrant, and an equal-altitude instrument, are applied.

Of all the different sorts of chronometers or timekeepers, a pendulum-clock, when properly constructed, is undoubtedly capable of the greatest accuracy, it being liable to fewer causes of obstruction or irregularity; therefore such machines are most recommendable for an observatory. The situation of this clock must be near the quadrant, and near the transit instrument; so that the observer, whilst looking through the telescope of any of those instruments, may hear the beats of the clock and count the seconds.

A pretty good telescope placed truly vertical in an observatory, is likewise a very useful instrument; as the aberration of the stars, latitude of the place, &c. may be observed and determined by the use of such an instrument, with great ease and accuracy.

The night telescope is a short telescope, which magnifies very little; but it collects a considerable quantity of light, and has a very great field of view; it therefore renders visible several dim objects, which cannot be discovered with telescopes of considerably greater magnifying powers, and hence it is very useful for finding out nebulæ, or small comets, or to see the arrangement of a great number of stars in one view.

The principal instruments that are at present used for marine astronomy, or for the purposes of navigation, are that incomparably useful instrument called Hadley's sextant, or quadrant, or octant; a portable chronometer; and a good telescope.

OBSIDIAN, in mineralogy, called also the Iceland agate, is found either in detached masses or forming a part of rocks. It has the appearance of black glass. It is usually invested with a grey or opaque crust. Its fracture is conchoidal. Specific gravity 2.35 nearly. Colour black, or greyish black; when in very thin pieces green. Very brittle. It melts into an opaque grey mass.

OCCULT, something secret, hidden, or invisible. The occult sciences are, magic, necromancy, cabbala, &c.

Occult, in geometry, is used for a line that is scarcely perceivable, drawn with the point of the compasses, or a leaden pencil. These lines are used in several operations, as the raising of plans, designs of building, pieces of perspective, &c. They are to be effaced when the work is finished.

OCCULTATION, in astronomy, the time a star or planet is hidden from our sight, by the interposition of the body of the moon, or of some other planet.

Occultation, *circle of perpetual*, is a parallel in an oblique sphere, as far distant from the depressed pole, as the elevated pole is from the horizon.

All the stars between this parallel and the depressed pole, never rise, but lie constantly hidden under the horizon of the place.

OCCUPANCY, in law, is a right which one acquires to a thing by being the first to gain possession of it. But this right is now chiefly done away by the English law.

OCEAN, in geography, that vast collection of salt and navigable waters, in which the two continents, the first including Europe, Asia, and Africa, and the last America, are inclosed like islands. The ocean is distinguished into three grand divisions. 1. The Atlantic Ocean, which divides Europe and Africa from America, which is generally about three thousand miles wide. 2. The Pacific Ocean, or South Sea, which divides America from Asia, and is generally about ten thousand miles over: and 3. The Indian Ocean, which separates the East Indies from Africa, which is three thousand miles over.

OCHRE, in natural history, a genus of earths, slightly coherent, and composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily diffusible in water. It is a combination of alumina and red oxide of iron.

OCTAGON, or **Octogon**, in geometry, is a figure of eight sides and angles; and this, when all the sides and angles are equal, is called a regular octagon, or one which may be inscribed in a circle.

Octagon, in fortification, denotes a place that has eight bastions.

OCTAHEDRON, or **Octaedron**, in geometry, one of the five regular bodies, consisting of eight equal and equilateral triangles. The octahedron is two pyramids put together at their bases; therefore its solidity may be found by multiplying the quadrangular base of either of them, by one third of the perpendicular height of one of them, and then doubling the product.

OCTANDRIA, the eighth class in Linnæus's sexual system; consisting of plants with hermaphrodite flowers, which are furnished with eight stamina, or male organs of generation.

OCTANT, or **Octile**, in astronomy, that aspect of two planets, wherein they are distant an eighth part of a circle, or 45°, from each other.

OCTAVE, in music, an interval containing seven degrees, or twelve semitones, and which is the first of the consonances in the order of generation.

OCTOBER, in chronology, the tenth month of the Julian year, consisting of thirty-one days: it obtained the name of October from its being the eighth month in the calendar

of Romulus. See the articles MONTH and YEAR.

ODE, in poetry, a song, or a composition proper to be sung. Among the ancients, odes signified no more than songs; but with us they are very different things. The ancient odes were generally composed in honour of their gods, as many of those of Pindar and Horace.

OESOPHAGUS, the gula, or gullet, is a membranaceous canal, reaching from the fauces to the stomach, and conveying into it the food taken in at the mouth. Its figure is somewhat like that of a funnel, and its upper part is called by anatomists the pharynx.

OESTRUS, a genus of insects of the order diptera: the generic character is, antennæ triarticulate, very short, sunk; face broad, depressed, vesicular; mouth, a simple orifice; feelers two, biarticulate, sunk; tail inflected. The genus *oestrus* or gad-fly is remarkable, like that of ichneumon, for the singular residence of its larvæ; viz. beneath the skin, or in different parts of the bodies of quadrupeds.

The principal European species is the oestrus bovis, or ox-gadfly. This is about the size of a common bee, and is of a pale yellowish-brown colour, with the thorax marked by four longitudinal dusky streaks, and the abdomen by a black bar across the middle, the tip being covered with tawny or orange-coloured hairs; the wings are pale brown, and unspotted.

The female of this species, when ready to deposit her eggs, fastens on the back of a heifer or cow, and piercing the skin with the tube situated at the tip of the abdomen, deposits an egg in the puncture; she then proceeds to another spot at some distance from the former, repeating the same operation at intervals on many parts of the animal's back. This operation is not performed without severe pain to the animal on which it is practised; and it is for this reason that cattle are observed to be seized with such violent horror when apprehensive of the approaches of the female oestrus: flying with uncontrolable rapidity, and endeavouring to escape their tormentor by taking refuge in the nearest pond; it being observed that this insect rarely attacks cattle when standing in water.

OFFENCE, is any act committed against any law. Offences are either capital or not capital. Capital offences are those for which an offender shall lose his life; not capital, where the offender may lose his lands and goods, be fined, or suffer corporal punishment, or both, but not loss of life.

OFFICE, is that function, by virtue whereof a person has some employment in the affairs of another. An office is a right to exercise any public or private employment, and to take the fees and emoluments thereunto belonging, whether public as those of magistrates, or private as of bailiffs, receivers, &c.

To offer money to any officer of state, to procure the reversion of an office in the gift of the crown, is a misdemeanor at common law, and punishable by information; and even the attempt to induce him, under the influence of a bribe, is criminal, though never carried into execution. An instance of which occurred under the administration of Mr. Addington, who prosecuted a tinman for offering a sum of money to him for a place in the customs.

Any contract to procure the nomination to an office, not within the statute 6, Edward VI, is defective on the ground of public policy; and the money agreed to be given is not recoverable.

OFFICER, a person possessed of a post or office. The great officers of the crown, or state, are the Lord High Steward, the Lord High Chancellor, the Lord High Treasurer, the Lord President of the Council, the Lord Privy Seal, the Lord Chamberlain, the Lord High Constable, the Earl Marshal.

OFFICERS, *field*, are such as command a whole regiment, as the colonel, lieutenant-colonel, and major.

OFFICERS, *general*, are those whose command is not limited to a single company, troop, or regiment; but extends to a body of forces, composed of several regiments: such are the general, lieutenant-general, major-generals, and brigadiers.

OFFICERS, *staff*, are such as, in the king's presence, bear a white staff, or wand; and at other times, on their going abroad, have it carried before them by a footman, bareheaded; such are the Lord Steward, Lord Chamberlain, Lord Treasurer, &c.

OFFICIAL, by the ancient law, signifies him who is the minister of, or attendant upon, a magistrate. In the canon law, it is especially taken for him to whom any bishop generally commits the charge of his spiritual jurisdiction; and in this sense there is one in every diocese called *officialis principialis*, whom the laws and statutes of this kingdom call chancellor. 32 Hen. VIII, 15.

OFFING, or **OFFIN**, that part of the sea a good distance from shore, where there is deep water, and no need of a pilot to conduct the ship.

OFF-SETS, are the young shoots that spring from the roots of plants; which being carefully separated, and planted in a proper soil, serve to propagate the species.

OFF-SETS, in surveying, are perpendiculars let fall, and measuring from the stationary lines to the hedge, fence, or extremity of an enclosure.

OGEE, or O. G. a moulding, consisting of two members, the one concave and the other convex; or, of a round and a hollow, like an S.

OIL. See CHEMISTRY.

OIL GAS. See GAS.

OLEA, the *olive-tree*, a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking under the 44th order, sapieriæ. The corolla is quadrifid, with the segments nearly ovate. The fruit is a monospermous plum. There are seven species; the most remarkable are:

1\. The *Europea*, or common olive-tree, rises with upright solid stems, branching numerously on every side, 20 or 30 feet high; spear-shaped, stiff, opposite leaves, two or three inches long, and half an inch or more broad: and at the axillas small clusters of white flowers, succeeded by oval fruit. This species is the principal sort cultivated for its fruit; the varieties of which are numerous, varying in size, colour, and quality. It is a native of the southern parts of Europe, and is cultivated in great quantities in the south of France, Italy, and Portugal, for the fruit to make the olive-oil.

2\. The *Capensis*, or Cape box-leaved olive

3. *Olea odoratissima*, the flower of which is by some said to give the fine flavour to the green tea; but Thunberg attributes the flavour to the cemellie seserque.

Oil of olives is an ingredient in the composition of a great many balsams, ointments, plasters, mollifying and relaxing liniments. It is of an emollient and solvent nature; mitigates gripes of the colic, and the pains accompanying dysentery; and is supposed a good remedy when any person has chanced to swallow corrosive poisons.

OLEFIANT GAS. A compound of one prime of carbon and one of hydrogen, to which I have given, says Dr. Ure, the name of CARBURETTED HYDROGEN, to distinguish it from the gas resulting from one prime of carbon and two of hydrogen, which I have called sub-carburetted hydrogen.

OLEIC-ACID, so called by Chevreul, is an oily matter obtained from potass and hogs'-lard saponified. This substance, according to Mr. Brand, solidifies at about 40°, forming compounds called *oleates*.

OLIBANUM. A gum resin, the product of the Juniperus Lycia, *Linn.* brought from Turkey and the East Indies, usually in drops or tears. The best is of a yellowish-white colour, solid, hard, and brittle: when chewed for a little time, it renders the spittle white, and impresses an unpleasant bitterish taste; laid on burning coals, it yields an agreeable smell.

OLIGARCHY, a form of government wherein the administration of affairs is lodged in the hands of a few persons. See GOVERNMENT.

OLIVE. See OLEA.

OLYMPIC GAMES, were solemn games, famous among the ancient Greeks, so called from Olympian Jupiter, to whom they were dedicated.

OLIVINE. A sub-species of prismatic chrysolite. Its colour is olive-green. It occurs massive and in roundish pieces. Rarely crystallized in imbedded rectangular four-sided prisms. Lustre shining. Cleavage imperfect double. Fracture small grained uneven. Translucent. Less hard than chrysolite. Brittle. Sp. gr. 3.24. With borax it melts into a dark green bead.

OLLARIS LAPIS, or *potstone*, its constituents are, silica 39, magnesia 16, oxide of iron 10, carbonic acid 20, water 10. It occurs in thick beds in primitive slate. It is found abundantly on the shores of the lake Como in Lombardy. It is fashioned into culinary vessels in Greenland. It is a sub-species of the rhomboidal mica of Professor Jameson.

OMPHACITE, a mineral found in Carinthia; it is of a pale leek-green colour. It is found massive, disseminated, and in narrow radiated concretions. It is a variety of augite.

OMNIUM, a term in use among stockbrokers to express all the articles included in the contract between government and the original subscribers to a loan. Thus if the subscribers, according to their agreement with government are to have for every hundred pounds advanced a certain sum in 3 per cent. consols, a further sum in 4 per cents, and a proportion of the long annuities, the blank receipts which they receive for making the instalments on the several articles, are, when disposed of, independent of each other, as the 3 per cent. consols only, called scrip; but when the receipts are sold together as originally received, they are usually called omnium. As the omnium of every loan is the subject of extensive speculations, it generally is liable to considerable variations with respect to its current price, sometimes selling at a high premium, at other times at a discount, according to the circumstances which take place between the agreement for the loan and the day fixed for paying the last instalment.

ONION. See ALLIUM.

ONYX. See CHALCEDONY.

OPACITY, that property in bodies by which they are rendered impervious to the rays of light.

The cause of opacity in bodies does not consist, as was formerly supposed, in the want of rectilinear pores, pervious every way; but either in the unequal density of the parts, in the magnitude of the pores, or in their being filled with a matter, by means of which the rays of light in their passage are arrested by innumerable refractions and reflections, become extinct, and are absorbed.

OPAL, in mineralogy: this stone is found in many parts of Europe, especially in Hungary, in the Crapacks near the village of Czennizka. When first dug out of the earth it is soft, but it hardens and diminishes in bulk by exposure to the air. The substance in which it is found is a ferruginous sand stone.

According to Jameson there are seven kinds of opal, viz.—precious opal, common opal, fire opal, mother-of-pearl opal, semiopal, Jasper opal, and wood opal.

OPERA, a dramatic composition set to music, and sung on the stage, accompanied with musical instruments, and enriched with magnificent dresses, machines, and other decorations.

OPERA-*glass*, in optics, so called from its use in theatres, &c.; it is sometimes called a "diagonal perspective" from its construction. It consists of a tube about four inches long, in each side of which there is a hole exactly against the middle of a plane mirror, which reflects the rays falling upon it, to the convex glass, through which they are re-refracted to the concave eye-glass, whence they emerge parallel to the eye at the hole in the tube. This instrument is not intended to magnify objects more than about two or three times. The peculiar artifice is to view a person at a small distance, so that no one shall know who is observed: for the instrument points to a different object from that which is viewed; and as there is a hole on each side, it is impossible, to know on which hand the object is situated, which you are looking at.

OPHIDIUM, in natural history, a genus of fishes of the order Apodes. Generic character: the head rather naked; teeth in the jaws, palate, and throat; gill membrane seven-rayed; body in the form of a sword. There are four species. We shall notice only O. *barbatum*, or the bearded ophidium: this is generally about eight inches long, and is a native of the Adriatic and Mediterranean Seas.

OPHTHALMIA, in medicine, an inflammation of the membranes which invest the eye.

OPIUM, in chemistry and medicine, an inspissated gummy juice, which is obtained from the head of the "papaver somniferum." It is imported from Persia, Arabia, and other warm parts of Asia, in flat cakes covered with leaves to prevent their sticking together. It has a reddish brown colour, and strong peculiar smell; its taste at first is nauseous and bitter; but this soon becomes acrid, and produces a slight warmth in the mouth. A peculiar substance has been detected in opium, to which it is supposed the properties it possesses of producing sleep are owing. On account of this property, this substance has received the name of narcotic matter. It is obtained from the milky juices of some plants, as those of the poppy, lettuce, and some others.

OPOBALSAMUM, or *balm of Gilead*, a resin obtained from the amyris Gileadensis, a tree which grows in Arabia, especially near Mecca. It is so much valued by the Turks, that it is rarely imported into Europe.

The true balsam is of a pale yellowish colour, clear and transparent, about the consistence of Venice turpentine, of a strong, penetrating, agreeable, aromatic smell, and a slightly bitterish purgent taste. By age it becomes yellower, browner, and thicker, losing by degrees, like volatile oils, some of its finer and more subtile parts.

OPODELDOC. A solution of soap in alcohol, with the addition of camphor and volatile oils. It is used externally against rhumatic pains, sprains, bruises, and other like complaints.

OPOPANAX. A concrete gummy resinous juice, obtained from the roots of an umbelliferous plant, the pastinaca opopanax, *Linn.* which grows spontaneously in the warmer countries, and bears the cold of this.

OPTICS. This word is derived from the Greek term *οπτομαι*, *I see*, and is used to denote that branch of natural philosophy which treats of the nature and properties of light, and of the changes which it undergoes either in its direction when transmitted through bodies, either natural or artificial,—when reflected from their surfaces, or when passing by them at a small distance.

Definitions.

1. Light is a substance, the particles of which are extremely small, and these by striking on our visual organs, give us the sensation of seeing.

2. The particles of light are emitted from what are called luminous bodies, such as the sun, a fire, a torch, or candle, &c. &c. It is reflected or sent back by what are termed opaque bodies, or those which have no power of affording light in themselves.

3. Light, whether emitted or reflected, always moves in straight or direct lines, as may easily be proved by looking into a bent tube, which evidently obstructs the progress of the light in direct lines.

4. By a ray of light, is usually meant the least particle of light that can be either intercepted or separated from the rest. A beam of light is generally used to express something of an aggregate or mass of light greater than a single ray.

5. Parallel rays are such as proceed equally distant from each other through their whole course. The distance of the sun from the earth is so immense, that rays proceeding from the body of that luminary are generally regarded as parallel.

6. Converging rays are such as, proceeding from any body, approach nearer and nearer to each other, and tend to unite in a point. The form of rays thus tending to an union in a single point has been compared to that of a candle-extinguisher; it is in fact a perfect cone.

7. Diverging rays are those which, proceeding from a point continue to recede from each other, and exhibit the form of an inverted cone.

8. A small object, or a small single point of an object, from which rays of light diverge, or indeed proceed in any direction, is sometimes called the radiant, or radiant point.

9. Any parcel of rays, diverging from a point, considered as separate from the rest, is called a pencil of rays.

10. The focus of rays is that point to which converging rays tend, and in which they unite and intersect, or cross each other. It may be considered as the apex or point of the cone; and it is called the focus (or fire-place), because it is the point at which burning-glasses burn most intensely.

11. The virtual or imaginary focus is that supposed point behind a mirror or looking glass, where the rays would have naturally united, had they not been intercepted by the mirror.

12. Plane mirrors or speculums are those reflecting bodies, the surfaces of which are perfectly plain or even, such as our common looking-glasses. Convex and concave mirrors are those the surfaces of which are curved.

13. An incident ray is that which comes from any body to the reflecting surface; the reflecting ray is that which is sent back or reflected.

14. The angle of incidence is the angle which is formed by the line which the incident ray describes in its progress, and a line drawn perpendicularly to the reflecting surface: and the angle of reflection is the angle formed by the same perpendicular and reflected ray. The angle comprehended between the incident ray and the perpendicular, is the angle of incidence; and that between the refracted ray and the perpendicular, is the angle of refraction.

15. By a medium opticians mean any thing which is transparent, such as void space, air, water, or glass, through which consequently the rays of light can pass in straight lines.

16. The refraction of the rays of light is their being bent, or attracted out of their course, in passing obliquely from one medium to another of a different density, and which causes objects to appear broken or distorted, when part of them is seen in a different medium.

17. A lens, is glass ground into such a form as to collect or disperse the rays of light which pass through it. These are of different shapes, and from thence receive different names. A plano convex has one side flat, and the other convex, as A (plate XXXVIII, fig. 1.) A plano-concave is flat on one side, and concave on the other, as B. A double convex, is convex on both sides as C. A double concave, is concave on both sides, as D,

A meniscus, is convex on one side and concave on the other, as E. A line passing through the centre of a lens, as FG, is called its axis.

18. Vision is performed by a contrivance of this kind. The crystalline humour, which is seated in the fore-part of the human eye, immediately behind the pupil, is a perfect convex lens.

19. The magnitude of the image painted on the retina will also depend on the greatness or obtuseness of the angle under which the pencil of rays proceeding from the extreme points of the object enters the eye.

20. The prism used by opticians is a triangular piece of fine glass, which has the power of separating the rays of light.

Of Refraction.

If the rays of light, after passing through a medium, enter another of a different density perpendicular to its surface, they proceed through this medium in the same direction as before. Thus the ray O P, fig. 2, proceeds to K, in the same direction. But if they enter obliquely to the surface of a medium, either denser or rarer than what they moved in before, they are made to change their direction in passing through that medium. If the medium which they enter be denser, they move through it in a direction nearer to the perpendicular drawn to its surface. Thus A C, upon entering the denser medium H G K instead of proceeding in the same direction A L is bent into the direction C F, which makes a less angle with the perpendicular O P. On the contrary, when light passes out of a denser into a rarer medium, it moves in a direction farther from the perpendicular. Thus, if S C were a ray of light which had passed through the dense medium H G K, on arriving at the rarer medium it would move in the direction C A, which makes a greater angle with the perpendicular. This refraction is greater or less, that is, the rays are more or less bent or turned aside from their course, as the second medium through which they pass is more or less dense than the first.

Upon a smooth board, about the centre C, describe a circle H O K P; draw two diameters of the circle, O P, H K, perpendicular to each other; draw A D M perpendicular to O P; cut off D T and C I equal to three-fourths D A; through T I, draw T I S, cutting the circumference in S; N S drawn from S perpendicularly upon O P, will be equal to D T, or three-fourths of D A. Then if pins be stuck perpendicularly at A, C, and S, and the board be dipped in the water as far as the line H K, the pin at S will appear in the same line with the pins at A and C. This shews, that the ray which comes from the pin S is so refracted at C, as to come to the eye along the line C A; whence the sine of incidence A D is to the sine of refraction N S, as 4 to 3. If other pins were fixed along C S, they would all appear in A C produced; which shows that the rays are bent at the surface only. The same may be shewn, at different inclinations of the incident ray, by means of a moveable rod turning upon the centre C, which always keep the ratio of the sines A D, N S, as 4 to 3. Also the sun's shadow, coinciding with A C, may be shown to be refracted in the same manner The image L, of a small object S, placed under water is one-fourth nearer the surface than the object. And hence the bottom of a pond, river, &c. is one-third deeper than it appears to a spectator.

To prove the refraction of light in a different way, take an upright empty vessel into a dark room; make a small hole in the window-shutter, so that a beam of light may fall upon the bottom at *a*, fig. 3, where you may make a mark. Then fill the bason with water, without moving it out of its place, and you will see that the ray, instead of falling upon *a*, will fall at *b*. If a piece of looking-glass be laid in the bottom of the vessel, the light will be reflected from it, and will be observed to suffer the same refraction as in coming in; only in a contrary direction. If the water be made a little muddy, by putting into it a few drops of milk, and if the room be filled with dust, the rays will be rendered much more visible.

On the subject of *double refraction*, some remarks will be found under the article *Polarization of Light*, to which the reader is referred.

On Reflexion.

When a ray of light falls upon any body, it is reflected, so that the angle of incidence is equal to the angle of reflection; and this is the fundamental fact upon which all the properties of mirrors depend. Let a ray of light, passing through a small hole into a dark room, be reflected from a plane mirror, at equal distances from the point of reflection, the incident, and the reflected ray, will be at the same height from the surface.

Again, if from a centre, C, with the radius, CA, the circle, A M P, be described, the arc, AO, will be found equal to the arc, O M, therefore the angle of incidence is equal to the angle of reflection. The same is found to hold in all cases when the rays are reflected at a curved surface, whether it be convex or concave. The rays which proceed from any remote terrestrial object, are nearly parallel at the mirror; not strictly so, but come diverging to it in separate pencils, or, as it were, bundles of rays, from each point of the side of the object next the mirror; therefore they will not be converged to a point at the distance of half the radius of the mirror's concavity from its reflecting surface, but in separate points at a little greater distance from the mirror. And the nearer the object is to the mirror, the further these points will be from it; and an inverted image of the object will be formed in them, which will seem to hang pendent in the air; and will be seen by an eye placed beyond it (with regard to the mirror,) in all respects like the object, and as distinct as the object itself.

If a man place himself directly before a large concave mirror, but further from it than its centre of concavity, he will see an inverted image of himself in the air, between him and the mirror, of a less size than himself. And if he hold out his hand towards the mirror, the hand of the image will come out towards his hand, and coincide with it, of an equal bulk, when his hand is in the centre of concavity; and he will imagine he may shake hands with his image. If he reach his hand further, the hand of the image will pass by his hand, and

come between it and his body; and if he move his hand towards either side, the hand of the image will move towards the other; so that whatever way the object moves, the image will move the contrary way. A by-stander will see nothing of the image, because none of the reflected rays that form it enter his eyes.

The images formed by convex specula are in positions similar to those of their objects; and those also formed by concave specula, when the object is between the surface and the principal focus: in these cases the image is only imaginary, as the reflected rays never come to the foci from whence they seem to diverge. In all other cases of reflexion from concave specula, the images are in positions contrary to those of their objects, and these images are real, for the rays after reflexion do come to their respective foci.

Of Colours.

The origin of colours is owing to the composition which takes place in the rays of light, each heterogeneous ray consisting of innumerable rays of different colours; this is evident from the separation that ensues in the well-known experiment of the prism. A ray being let into a darkened room, fig. 4, through a small round aperture *z*, and falling on a triangular glass prism, *x*, is by the refraction of the prism considerably dilated, and will exhibit on the opposite wall an oblong image, *a b*, called a spectrum, variously coloured, the extremities of which are bounded by semicircles, and the sides are rectilinear. The colours are commonly divided into seven, which, however, have various shades, gradually intermixing at their juncture. Their order, beginning from the side of the refracting angle of the prism, is red, orange, yellow, green, blue, purple, violet.

The obvious conclusion from this experiment is, that the several component parts of solar light have different degrees of refrangibility, and that each subsequent ray in the order above mentioned is more refrangible than the preceding.

As a circular image would be depicted by the solar ray unrefracted by the prism, so each ray that suffers no dilatation by the prism, would mark out a circular image. Hence, it appears, that the spectrum is composed of innumerable circles of different colours. The mixture, therefore, is proportionable to the number of circles mixed together; but all such circles are mixed together, whose centres lie between those of two contingent circles, consequently the mixture is proportionable to the interval of those centres, *i. e.* to the breadth of the spectrum. If, therefore, the breadth can be diminished, retaining the length of the rectilinear sides, the mixture will be lessened proportionably, and this is done by the following process.

At a considerable distance from the hole *z*, place a double convex lens, fig. 5, whose focal length is equal to half that distance, and place the prism *x* behind the lens; at a distance behind the lens, equal to the distance of the lens from the hole, will be formed a spectrum, the length of whose rectilinear sides is the same as before, but its breadth much less; for the undiminished breadth was equal to a line subtending, at the distance of the spectrum from the hole, an angle equal to the apparent diameter of the sun, together with a line equal to the diameter of the hole; but the reduced breadth is equal to the diameter of the hole only. The image of the hole formed by the lens, at the distance of double its focal length, is equal to the hole; therefore, its several images in the different kinds of rays are equal to the same, *i. e.* the breadth of the reduced spectrum is equal to the diameter of the hole

A prism placed in an horizontal position would project the ray into an oblong form apply another horizontal prism, similar to the former, to receive the refracted light emerging from the first; and having its refracted angle turned the contrary way from that of the former, the light, after passing through both prisms, will assume a circular form, as if it had not been at all refracted.

If the light emerging from the first prism be received by a second, whose axis is perpendicular to that of the former, it will be refracted by this transverse prism into a position inclined to the former, the red extremity being least, and the violet most removed from its former position; but it will not be at all altered in breadth.

Close to the prism A, fig. 6, place a perforated board *a b*, and let the refracted light, having passed through the small hole, be received on a second board *c d*, parallel to the first, and perforated in like manner: behind that hole in the second board, place a prism, with its refracting angle downward; turn the first prism slowly about its axis, and the light will move up and down the second board let the colours be transmitted successively, and mark the places of the different coloured rays on the wall after their refraction by the second prism, the red will appear lowest, the violet highest, the rest in the intermediate places in order. Here, then, the light being very much simplified, and the incidences of all the rays on the second prism exactly the same; the red was least refracted, the violet most, &c.

The permanency of these original colours appears from hence, that they suffer no manner of change by any number of refractions, as is evident from the last mentioned experiment; nor yet by reflexion; for if any coloured body be placed in simplified homogeneous light, it will always appear of the same colour of the light in which it is placed, whether that differ from the colour of the body or not; *e. g.* if ultramarine and vermilion be placed in red light, both will appear red; in a green light, green; in a blue light, blue, &c. It is, however, to be allowed, that a body appears brighter when in a light of its own colour than in another; and from this we see that the colours of natural bodies arise from an aptitude in them to reflect some rays more copiously and strongly than others; but lest this phenomenon should produce a doubt of the constancy of the primary colours, it is proper to assign the reason of it, which is this: that when placed in its own coloured light, the body reflects the rays of the predominant colour more strongly than any of those intermixed with it; therefore the proportion of the rays of the predominant colour to those of the others, in the reflected light, will be greater than in the incident light; but when the body is placed in a light of a different colour from its own, for a similar reason the contrary effect

will follow; *i. e.* the proportion of the predominant colour to the others will be less in the reflected than in the incident light, and therefore as its splendor would be greater in the former case, and would be less in the latter than if all the rays were equally reflected, the splendour of the predominant colour will be much greater in the former case than in the latter.

White is compounded of all the primary colours mixed in their due proportions; for if a solar ray be separated by the prism into its component parts, and at a proper distance a lens be so placed as to collect the diverging coloured rays again into a focus, a paper placed perpendicularly to the rays in this point will exhibit whiteness.

The following is a very pleasing and satisfactory method of illustrating this fact.

Draw two concentric circles, fig. 7, on a piece of stiff card-paper; from the centre draw the lines A B C D E F G, to the circumference of the outer circle, making them at the distance from each other in degrees as expressed in the figure. Then between the two circles paint the space A G red, inclining to orange near G; G F orange, inclining to yellow near F; F E yellow, inclining to green near E; E D green, inclining to blue near D; D C blue, inclining to indigo near C; C B indigo, inclining to violet near B; and B A violet, inclining to a soft red near A.

Let all that part of the card within the inner circle be painted black. If now an axis be passed through the centre of the card, and the card made to revolve very rapidly upon it, the whole of the colours will appear so blended together as to present the appearance of a white ring, inclining a little to grey. Any of these colours may be made by mixing together the two contiguous prismatic colours.

Though seven different colours are distinguishable in the prismatic spectrum, yet, upon examining the matter with more accuracy, we shall see that there are, in fact, only three original colours, red, blue, and yellow; for the orange being situated between the red and yellow, is only the mixture of these two: the green, in like manner, arises from the blue and yellow; and the violet from the blue and red.

As the colour of a body, therefore, proceeds from a certain combination of the primary rays which it reflects, the combination of rays flowing from any point of an object will, when collected by a glass, exhibit the same compound colour in the corresponding point of the image. Hence appears the reason why the images formed by glasses have the colours of the object which they represent.

Of Vision.

The eye is nearly of a spherical shape, and is composed of three different substances, called, 1. The aqueous, P, fig. 8. 2. The crystalline, R; and 3, the vitreous humours, V, enclosed by three principal coats, which are formed by the expansion of the different component parts of the optic nerve, *viz.* the sclerotica, S S. 2. The choroides, D D; and 3. The retina, T T. The sclerotica is outermost; it is very strong, and the fore part, which is transparent, and somewhat prominent, is called the cornea, C. The choroides is next in order, and has a circular perforation, P, called the pupil, immediately behind the middle of the cornea: the part H of the choroides, visible behind the cornea, is flat; it is called the iris, or uvea, and is differently coloured in different persons. The retina is the inmost coat; it extends round the eye till it meets the ciliary ligaments, Q Q, membranes proceeding from the choroides and attached to the capsula or filament, which incloses the crystalline humour, R. The crystalline is the most dense of the three humours, and is in the shape of a double convex lens, whose fore part has the less curvature; the cavity between the cornea and the crystalline is occupied by the aqueous humour, which has rather the least density of the three, and the space between the bottom of the eye and the crystalline is filled by the vitreous humour V.

Objects presented to the eye have their images painted on the back part of the retina, the rays of the incident pencils converging to their proper foci there by the refraction of the different humours; and for this office they are admirably adapted; for as the distance between the back and front of the eye is very small, and the rays of each of the pencils that form the image fall parallel, or else diverging on the eye, a strong refractive power is necessary for bringing them to their foci at the retina; but each of the humours, by its peculiar form and density, contributes to cause a convergence of the rays: the aqueous from its convex form; the crystalline by its double convexity and greater density than the aqueous; and the vitreous by a less density than the crystalline joined to its concave form.

The structure of the eye is in general adapted to the reception of parallel rays, but as the distances of visible objects are various, so the eye has powers of accommodating itself to rays proceeding from different distances by altering the distances of the crystalline from the retina, which is done by the action of the ciliary ligaments.

Defective sight arises from an incapacity of altering the position of the crystalline within the usual limits. 1. When it cannot be brought close enough to the cornea, near objects appear indistinct; to this defect people in years are generally subject. 2. Where the crystalline cannot be drawn sufficiently near to the retina, remote objects appear indistinct; this is the defect under which short-sighted people labour. In each of these cases the images of the different points in the object would be diffused over small circles on the retina; and so being intermixed and confounded with each other, would there form a very confused picture of the object; for in the former case, fig. 5, the image of any point would be formed behind the retina, as the refraction of the eye is not sufficiently strong to bring the rays (diverging so much as they do in proceeding from a near point) to a focus at the retina. This defect will therefore be remedied by a convex glass *ab*, which makes the point whence the rays now proceed more distant than the object: therefore the rays falling on the eye will now diverge less than before, or else be parallel, and will of course be brought to a nearer focus, viz. at the retina.

In the latter case, the image is formed before the retina, fig. 6, because the refractive power of the eye is too great to permit rays so little diverging (as they do in proceeding

from a distant point) to reach the retina before they are collected into a focus; in this case the defect is supplied by a concave glass, which makes the point whence the rays diverge, nearer than the object: consequently, the rays falling on the eye will now diverge more than before, so as when refracted through the humours not to come to their focus before they reach the retina. Therefore spectacles are constructed concave for short-sighted, and convex for long-sighted people.

Of Optical Instruments.

From what has been stated concerning vision, the principle of the single microscope will be easily understood. Since the eye cannot have a distinct preception of any object at a nearer distance than six or eight inches, and since there are many objects which at that distance must be wholly imperceptible, or at best appear as points, an instrument which can render them visible, is a very desirable attainment.

The most powerful single microscopes are very small globules of glass, which any curious person may make for himself by melting the ends of fine threads of glass in the flame of a candle; or by taking a little fine powdered glass on the point of a very small needle, and melting it into a globule in that way. It was with such microscopes as these that Lewenhoeck made all his wonderful discoveries, most of which are deposited in the British Museum.

The double or compound microscope differs from the preceding in this respect, that it consists of at least two lenses, by one of which an image is formed within the tube of the microscope; and this image is viewed through the eye-glass, instead of the object itself as in the single microscope. In this respect the principle is analogous to that of the telescope, only that, as the latter is intended to view distant objects, the object-lens, is of a long focus, and consequently of a moderate magnifying power, and the eye-glass of a short focus, which magnifies considerably the image made by the object-lens. Whereas the microscope being intended only for minute objects, the object-lens is consequently of a short focus, and the eye-glass in this case is not of so high a magnifying power.

A single figure will serve to explain the principles on which all these instruments are constructed. Suppose therefore L N, fig. 9, to be the object-lens, and F G to be the eye-glass. The object O B is placed a little beyond the principal focus of L N. The cones or pencils of rays then proceeding from the different points of the object, are by the lens made to converge to their respective foci, and form an inverted image of the object at P Q. This image is seen through the eye-glass F G, and the rays of each pencil will proceed in a parallel direction to the pupil of the eye.

The solar microscope is a kind of camera obscura, which, in a darkened chamber, throws the image on a wall or screen. It consists of two lenses fixed opposite a hole in a board or window-shutter; one, which condenses the light of the sun upon the object (which is placed between them), and the other which forms the image. There is also a plain reflector placed without, moved by a wheel and pinion, which may be so regulated as to throw the suns's rays upon the outer lens. Mr. Adam's most ingenious invention, the lucernal microscope, is also to be considered as a kind of camera obscura; only the light in this latter case proceeds from a lamp, instead of from the sun, which renders it convenient to be used in all times. But for a description of this elegant and most amusing instrument, we must refer to his Microscopical Essays.

From what has been said on the nature of the compound microscope, the principle of the telescope may be easily understood. Telescopes are, however, of two kinds: the one depending on the principle of refraction, and called the dioptric-telescope; the other on the principle of reflexion, and therefore termed the reflecting telescope.

The parts essential to a dioptric-telescope are, the two lenses A D and E Y, fig. 10. As in the compound microscope, A D is the object-glass, and E Y is the eye-glass; and these glasses are so combined in the tube, that the focus F of the one is exactly coincident with the focus of the other.

Let O B then represent a very distant object, from every point of which pencils of rays will proceed so little diverging to the object-lens A D, that they may be considered as nearly parallel; I M will then be the image which would be formed on a screen by the action of the lens A D. For supposing O A and B D two pencils of rays proceeding from the extreme points of the object, they will unite in the focal point F, and intersect each other. But the point F is also the focus of the eye-glass E Y; and therefore the pencil of rays, instead of going on to diverge, will pass through it in nearly a parallel direction, so as to cause distinct vision. It is then plain that, as in the compound microscope, it is the image which is here contemplated; and this will account for the common sensation when people say the object is brought nearer by a telescope. For the rays, which after crossing proceed in a divergent state, fall upon the lens E Y, as if they proceeded from a real object situated at F. All that is effected by a telescope then is, to form such an image of a distant object, by means of the object-lens, and then to give the eye such assistance as is necessary for viewing that image as near as possible; so that the angle it shall subtend at the eye shall be very large compared with the angle which the object itself would subtend in the same situation. This is effected by means of the eye-glass which refracts the pencils of rays, so that they may be brought to their several foci by the humours of the eye, as has been described. To explain clearly, however, the reason why it appears magnified, we must again have recourse to the figure. O B being at a great distance, the length of the telescope is inconsiderable with respect to it. Supposing, therefore, the eye viewed it from the centre of the object-glass C, it would see it under the angle O C B: let O C and B C then be produced to the focus of the glass, they will then limit the image I M formed in the focus If these two parallel rays are supposed to proceed to the eye-glass E Y, they will be converged to its focus H, and the eye will see the image under the angle E H Y. The ap-

parent magnitude of the object seen by the naked eye is, therefore, to that of the image which is seen through the telescope, as the magnitude of the angle O C B, or I C M, to that of E H Y, or I G M. Now the angle I G M is *to* I C M as C F to F G; *that is*, as the focal length of the object-glass *to that of* the eye-glass.

The magnifying power of these glasses may be augmented to a considerable degree, because the focal length of the object-glass, with respect to that of the eye-glass, may be greatly increased. This, however, would require a tube of immense length; because an eye-glass of a very short focus would cause such a dispersion of the rays of light, particularly towards the edges of the glass, that the view would be intercepted by the prismatic colours.

Another manifest defect in these telescopes is, that the image appears inverted; this, however, is of no consequence with respect to the heavenly bodies; and on this account it is still used as an astronomical telescope. One of almost a similar construction is also used on board of ships as a night-glass, to discover rocks in the ocean, or an enemy's fleet. Notwithstanding the inconvenience of exhibiting the objects inverted, more glasses than two cannot be employed from the paucity of light; and habit soon enables the persons who use them to discern objects with tolerable distinctness.

The brightness of the appearance through any of these telescopes or microscopes, depends chiefly on the aperture of the object-glass. For if the whole of that glass was covered except a small aperture in the middle, the magnitude of the image would not be altered; but fewer rays of every pencil being admitted, the object would appear obscure. In few words, the apparent distinctness or confusion of any object, viewed through glasses, depends on the mutual inclinations of the rays in any one pencil to each other, when they fall on the eye; the apparent magnitude depends upon the inclination of the rays of different pencils to each other; the apparent situation depends upon the real situation of the extreme pencils; and the apparent brightness or obscurity depends on the quantity of rays in each pencil. The well-known property in concave speculums, of causing the pencils of rays to converge to their foci, and there forming an image of an object that may be opposed to them, gave rise to the reflecting telescope. In this the effect is precisely the same as that produced by the dioptric telescope; only that in the one case it is produced by reflected, and in the other by refracted, light. Reflecting telescopes are made in various forms; and those principally in use in this country are distinguished by the names of their respective inventors, and are called the Newtonian, Gregorian, and Herschelian telescopes. The reflecting telescope on the Gregorian principle, which is the most common, as it is found to be the most convenient, is constructed in the following manner:—At the bottom of the great tube, plate XXXIX, fig. 1, T T T T, is placed a large concave mirror D U V F, whose principal focus is at *m*; and in the middle of this mirror is a round hole P, opposite to which is placed the small mirror L, concave toward the great one; and so fixed to a strong wire M that it may be removed further from the great mirror, or nearer to it by means of a long screw on the inside of the tube, keeping its axis still in the same line P *m n* with that of the great one. Now, since in viewing a very remote object, we can scarcely see a point of it but what is, at least, as broad as the great mirror, we may consider the rays of each pencil, which flow from every point of the object, to be parallel to each other, and to cover the whole reflecting surface D U V F. But to avoid confusion in the figure, we shall only draw two rays of a pencil flowing from each extremity of the object into the great tube; and trace their progress through all their reflections and refractions to the eye *f* at the end of the small tube *t t*, which is joined to the great one.

Let us then suppose the object AB to be at such a distance, that the rays C may flow from its upper extremity A, and the rays E from its lower extremity B; then the rays C falling parallel upon the great mirror at D, will be thence reflected converging in the direction D G: and by crossing at I in the principal focus in the mirror, they will form the lower extremity of the inverted image I K, similar to the upper extremity A of the object A B; and passing on to the concave mirror L (whose focus is at *n*), they will fall upon it at *g*, and be thence reflected, converging in the direction *g* N, because *g m* is longer than *g n*: and passing through the hole P in the large mirror, they would meet somewhere about *r*, and form the upper extremity *a* of the erect image *ab*, similar to the upper extremity A of the object AB.

But by passing through the plano convex-glass R in their way, they form that extremity of the image at *a*. In the same manner the rays E, which come from the bottom of the object AB, and fall parallel upon the great mirror at F, are thence reflected, converging to its focus; where they form the upper extremity I of the inverted image I K, similar to the lower extremity B of the object A B: and thence passing on to the small mirror L, and falling upon it at *h*, they are thence reflected in the converging state *h* O; and going on through the hole P of the great mirror, they would meet somewhere about *q*, and form there the lower extremity *b* of the erect image *a b*, similar to the lower extremity B of the object A B; but by passing through the convex glass R in their way, they meet and cross sooner, as at *b*, where that point of the erect image is formed. The like being understood of all those rays which flow from the intermediate points of the object between A and B, and enter the tube T T, all the intermediate points of the image between *a* and *b* will be formed; and the rays passing on from the image through the eye-glass S, and through a small hole *e* in the end of the lesser tube *t t*, they enter the eye *f*, which sees the image *a b* (by means of the eye-glass) under the large angle *c e d*, and magnified in length under that angle from *c* to *d*.

In the best reflecting telescopes, the focus of the small mirror is never coincident with the focus *m* of the great one, where the first image I K is formed, but a little beyond it (with respect to the eye) as at *n*; the consequence of which is, that the rays of the pen-

cils will not be parallel after reflection from the small mirror, but converge so as to meet in points about *q, e, r:* where they would form a larger upright image than *ab*, if the glass R was not in their way, and this image might be viewed by means of a single eye-glass properly placed between the image and the eye; but then the field of view would be less, and consequently not so pleasant; for that reason the glass R is still retained, to enlarge the scope or area of the field.

To find the magnifying power of this telescope, multiply the focal distance of the great mirror by the distance of the small mirror from the image next the eye, and multiply the focal distance of the small mirror by the focal distance of the eye-glass; then divide the product of the former multiplication by that of the latter, and the quotient will express the magnifying power. The difference between the Newtonian and Gregorian telescope is, that in the former the spectator looks in at the side through an aperture upon a plane mirror, by which the rays reflected from the concave mirror are reflected to the eye-glass; whereas in the latter the reader will see that he looks through the common eye-glass, which is in general more convenient.

The immensely powerful telescopes of Dr. Herschel are of a still different construction. This assiduous astronomer has made several specula, which are so perfect as to bear a magnifying power of more than six thousand times in diameter on a distant object. The object is reflected by a mirror as in the Gregorian telescope, and the rays are intercepted by a lens at a proper distance, so that the observer has his back to the object, and looks through the lens at the mirror. The magnifying power will in this case be the same as in the Newtonian telescope; but there not being a second reflector, the brightness of the object viewed in the Herschelian is greater than that in the Newtonian or Gregorian telescope. In conclusion, Sir Isaac Newton's excellent maxim must not be omitted: "The art," says he, "of constructing good microscopes and telescopes may be said to depend on the circumstance of making the last image as large and distinct and luminous as possible.

The camera obscura is an instrument used to facilitate the delineation of prospects. It is constructed in the following manner: A C, fig. 2. represents a box of about a foot and a half square, shut on every side, except D C; O P is a smaller box placed on the top of the greater; N N is a double convex lens, whose axis makes an angle of 45° with B L, a plane mirror fixed in the box O P; the focal length of the lens is nearly equal to C S + S T, *i. e.* to the sum of the distances of the lens from the middle of the mirror and of the middle of the mirror from the bottom of the larger box.

The lens being turned towards the prospect would form a picture of it, nearly at its focus; but the rays being intercepted by the mirror will form the picture as far before the surface as the focus is behind it, *i. e.* at the bottom of the larger box, a communication being made between the boxes by the vacant space Q O. The draughtsman then putting his head and hands into the box through the open side, D C, and drawing a curtain round to prevent the admission of the light, which would disturb the operation, may trace a distinct outline of the picture that appears on the bottom of the box.

There is another kind of camera obscura, constructed thus. In the extremity of the arm, P Q, fig. 3, that extends from the side of a small square box, B L, is placed a double convex lens, whose axis is inclined in an angle of 45° to a plane mirror B O: the focal length of the lens is equal to its distance from the side of the box O T; therefore when the lens is turned towards the illuminated prospect it would project the image on the side OT, if the mirror were removed, but this will reflect the image to the side M L, which is as far distant from the middle of the mirror, as this is from the side O T; it is there received on a piece of glass, rough at the upper side and smooth at the lower, and appears in its proper colours on the upper side of the plate. It is evident that in each of these instruments the image is inverted with respect to the object.

M S is a lid to prevent the admission of light during the delineation of the picture, and others for the same purpose are applied to the sides M R and N L.

Dr. Wollaston has recently invented a portable instrument for drawing in perspective, to which he has given the name of camera lucida.

The instrument, as represented in the figures, may be used either with the small round glass turned up in front, fig. 4, or with the larger glass turned up level underneath the instrument, fig. 5, *(seen from above.)* But those who are short-sighted can only use the former, and persons that are long-sighted must use the latter.

The prism is next to be turned upon its pin, till the transparent rectangular face be placed opposite to the objects to be delineated, when the upper black surface of the eye-piece E, will be on the top of the instrument; and through the aperture in this, the artist is to look perpendicularly downwards at his paper.

The black eye-piece E, is moveable, and, in ordinary circumstances is to be in such a position, that the edge of the small transparent part at the back of the prism shall intercept about half the eye-hole. The artist then, looking through the eye-hole directly downwards at his paper, should see the object he wishes to draw, apparently distributed over the paper. For, since his eye is larger than the eye-hole, he sees through both halves of the hole at the same time, without moving his head. He sees the paper through the nearer half, and sees the objects at the same time through the farther half, apparently in the same direction, by means of reflection, through the prism.

The position of the EYE-HOLE, is the circumstance, above all others, necessary to be attended to in adjusting the camera lucida for use; for on the due position of this hole depends the possibility of seeing both the pencil and the objects distinctly at the same time

If the eye-hole be moved, so that nearly the whole of its aperture be over the paper, and a very small portion over the prism, then the pencil and paper will be very distinctly seen; but the objects to be delineated, very dimly. If, on the other hand, the aperture be mostly over the prism, and but a small portion over

the paper, then the objects will be seen distinctly, but the pencil and paper will be very faint. But there will always be an intermediate position (varying according as the objects or the paper happen to be most illuminated) in which both will be sufficiently visible for the purpose of delineation, though not quite so clear as to the naked eye. This intermediate position is easily found with a little practice.

In copying drawings, the copy will be larger or smaller than the original, according as the prism is more or less distant from the paper than it is from the drawing to be copied. Thus, if the drawing be two feet from the prism, and the paper only one foot, the copy will be half the size of the original. If the drawing be at one foot, and the paper three feet distant, the copy will be three times as large as the original; and so for all other distances.

The magic lantern is an optical instrument invented by Athanasius Kircher, the use of which is to magnify small paintings on glass. The construction and use of this instrument will be seen by inspecting fig. 6. A B C D represents a tin lantern, from one side of which there proceeds the square tube *b n k l m c*, consisting of two parts: the outermost of which *n k l m*, slides over the other, so, that the whole tube may be lengthened or shortened by that means. In the end of the arm *n k l m*, is fixed a convex lens, *k l*; about *d e* there is an opening for admitting an object as *d e*, painted in dilute and transparent colours, on a plane of thin clear glass, which object is there placed in an inverted position A single or double convex lens *b h c* is employed for casting the light from the flame of the candle or lamp *a*, very strongly on the picture *d e*. If the object *d e* be placed further from the lens *k l* than its focus, a distinct image of the object will be projected by the glass *k l* upon the opposite white wall or screen F H, at *f g*, and it will be in an erect position.

The apartment in which the exhibition is made must be completely darkened. To increase the light a concave mirror O P is generally placed behind the lamp, having the flame as nearly as possible in its focus.

The exhibition called the phantasmagoria differs from the magic lantern only in the following particulars, *viz*, the sliders are made perfectly opaque except where the figures are introduced; and the screen on which the images are thrown is placed between the lantern and the spectators.

Various methods of preparing muslin for these screens have been tried; but the best, and by far the cheapest is that of simply dipping it in clean water before it is used, which renders it beautifully transparent. The phantasmagoria is finely adapted for exhibiting telescopic views of the heavenly bodies, for which purpose it is much used by public lecturers. A description of a very improved phantasmagoria may be seen in Dr. Young's **Lectures** on *Natural Philosophy*, vol. I. p. 426, 785.

Of the Rainbow and other phenomena of Light.

Since the rays of light are found to be decompounded by refracting surfaces, we can no longer be surprised at the changes produced in any object by the intervention of another. The vivid colours which gild the rising or the setting sun, must necessarily differ from those which adorn its noon-day splendour. There must be the greatest variety which the liveliest fancy can imagine. The clouds will assume the most fantastic forms, or will lour with the darkest hues, according to the different rays which are reflected to our eyes, or the quantity absorbed by the vapours in the air. The ignorant multitude will necessarily be alarmed by the sights in the heavens; by the appearance at one time of three, at another of five suns; of circles of various magnitudes round the sun or moon; and thence conceive that some fatal change must take place in the physical or the moral world, some fall of empires or tremendous earthquake: while the optician contemplates them merely as the natural and beautiful effects produced by clouds or vapour in various masses upon the rays of light.

One of the most beautiful and common of these appearances deserves particular investigation, as, when this subject is well understood, there will be little difficulty in accounting for others of a similar nature, dependent on the different refrangibility of the rays of light. Frequently when our backs are turned to the sun, and there is a shower either around us or at some distance before us, a bow is seen in the air, adorned with all or some of the seven primary colours. The appearance of this bow, in poetical language called the iris, and in common language the rainbow, was an inexplicable mystery to the ancients; and, though now well understood, continues to be the subject of admiration to the peasant and the philosopher.

We are indebted to Sir Isaac Newton for the explanation of this appearance; and by various easy experiments we may convince any man that his theory is founded on truth. If a glass globe is suspended in the strong light of the sun, it will be found to reflect the different prismatic colours exactly in proportion to the position in which it is placed; in other words, agreeably to the angle which it forms with the spectator's eye and the incidence of the rays of light. The fact is, that innumerable pencils of light fall upon the surface of the globe, and each of these is separated as by a prism. To make this matter still clearer, let us suppose the circle B A W, fig. 7, to represent the globe, or a drop of rain, for each drop may be considered as a small globe of water. The red rays, it is well known, are least refrangible; they will therefore be refracted, agreeably to their angle of incidence, to a certain point A in the most distant part of the globe; the yellow, the green, the blue, and the purple rays, will each be refracted to another point. A part of the light, as refracted, will be transmitted, but a part also will be reflected; the red rays at the point A, and the others at certain other points, agreeably to their angle of refraction.

It is very evident that if the spectator's eye is placed in the direction of M W, or the course of the red-making rays, he will only distinguish the red-colour; if in another situation, he will see only by the yellow rays; in another by the blue, &c. but as in a shower of rain there are drops at all heights and all distances, all those that are in a certain position with respect to the spectator will reflect the red rays, all those in the next

station the orange, those in the next the green, &c

To avoid confusion let us imagine only three drops of rain, and three degrees of colours in the section of a bow, fig. 8. It is evident that the angle C E P is less than the angle B E P, and that the angle A E P is the greatest of the three. This largest angle then is formed by the red rays, the middle one consists of the green, and the smallest is the purple. All the drops of rain therefore, that happen to be in a certain position to the eye of the spectator, will reflect the red rays, and form a band or semicircle of red; those again in a certain position will present a band of green, &c. If he alters his station, the spectator will still see a bow, though not the same bow as before; and if there are many spectators they will each see a different bow, though it appears to be the same.

There are sometimes seen two bows, one formed as has been described, the other appearing externally to embrace the primary bow, and which is sometimes called a secondary or false bow, because it is fainter than the other; and what is most remarkable is, that in the false bow the order of the colours appears always reversed.

In the true or primary bow we have seen that the rays of light arrive at the spectator's eye after two refractions and one reflexion: in the secondary bow the rays are sent to our eyes after two refractions and two reflexions, and the order of the colours is reversed, because in this latter case the light enters at the inferior part of the drop, and is transmitted through the superior.

Thus fig. 9, the ray of light which enters at B is refracted to A, whence it is reflected to P, and again reflected to W, where, suffering another refraction, it is sent to the eye of the spectator. The colours of this outer bow are fainter than those of the other, because, the drop being transparent, a part of the light is transmitted, and consequently lost, at each reflection.

The phenomenon assumes a semicircular appearance, because it is only at certain angles that the refracted rays are visible to our eyes. The least refrangible, or red rays, make an angle of 42 degrees two minutes, and the most refrangible, or violet rays, an angle of 40 degrees, 47 minutes. Now if a line is drawn horizontally from the spectator's eye, it is evident that angles formed with this line, of a certain dimension in every direction, will produce a circle; as will be evident by only attaching a cord of a given length to a certain point, round which it may turn as round its axis, and in every point will describe an angle with the horizontal line of a certain and determinate extent.

Let H O, for instance, fig. 9, represent the horizon, B W a drop of rain at any altitude, S B a line drawn from the sun to the drop, which will be parallel to a line S M drawn from the eye of the spectator to the sun. The course of part of the decompounded ray S B may be first by refraction from B to A, then by reflexion from A to W, lastly by refraction from W to M. Now all drops which are in such a situation that the incident and emergent rays S B, M W, produced through them make the same angle S N M, will be the means of exciting in the spectators the same idea of colour. Let M W turn upon H O as an axis, till W meets the horizon on both sides, and the point W will describe the arc of the circle: and all the drops placed in its circumference will have the property we have mentioned, of transmitting to the eye a particular colour. When the plane H M W A is perpendicular to the horizon, the line M W is directed to the vertex of the bow, and WK is its altitude.

This altitude depends on two things, the angle between the incident and emergent rays, and the height of the sun above the horizon; for since S M is parallel to SN, the angle S N M is equal to N M I: but S M H, the altitude of the sun, is equal to K M I; therefore the altitude of the bow W M K, which is equal to the difference between W M I and K M I, is equal to the difference between the angles made by the incident and emergent rays and the altitudes of the sun.

The angle between the incident and emergent rays is different for the different colours, as was already intimated; for the red, or least refrangible, rays, it is equal to 42° 2′; for violet, or most refrangible, it is equal to 40° 17′; consequently when the sun is more than 40° 2′ above the horizon, the red colour cannot be seen; when it is above 40° 17′ the violet colour cannot be seen.

The secondary bow is made in a similar manner; but the sun's rays suffer, in this case, two reflexions within the drop. The ray S B, fig. 9, is decompounded at B; and one part is refracted to A, thence reflected to P, and from P reflected to W, where it is refracted to M. The angle between the incident and emergent rays S M N is equal as before to N M I; and N M K, the height of the bow, is equal to the difference between the angle made by the incident and emergent rays and the height of the sun. In this case the angle S N M, for the red rays is equal to 50° 7′, and for the violet rays it is equal to 54° 7′; consequently the upper part of the secondary bow will not be seen when the sun is above 54° 7′ above the horizon, and the lower part of the bow will not be seen when the sun is 50° 7′ above the horizon.

In the same manner innumerable bows might be formed by a greater number of reflexions within the drops; but as the secondary is so much fainter than the primary, that all the colours in it are seldom seen, for the same reason a bow made with three reflections would be fainter still, and in general, altogether imperceptible. Since the rays of light, by various reflexions, are thus capable of forming by means of drops of rain, the bows which we so frequently see in the heavens, it is evident that there will be not only solar and lunar bows, but that many striking appearances will be produced by drops upon the ground, or air on the agitated surface of the water. Thus, a lunar bow will be formed by rays from the moon effected by drops of rain; but as its light is very faint in comparison with that of the sun, such a bow will very seldom be seen, and the colours of it, when seen, will be faint and dim.

The marine or sea-bow is a phenomenon sometimes observed in a much agitated sea; when the wind, sweeping part of the top of

waves, carries them aloft, so that the sun's rays, falling upon them, are refracted, &c., as in a common shower, and paint the colours of the bow.

Rohault mentions coloured bows on the grass formed by the refraction of the sun's rays in the morning dew.

Dr. Langwith, indeed, once saw a bow lying on the ground, the colours of which were almost as lively as those of the common rainbow. It was extended several hundred yards. It was not round, but oblong, being, as he conceived, the portion of an hyperbola.

The drops of rain descended in a globular form, and thence we can easily account for the effects produced by them on the rays of light: but in different states of the air, instead of drops of rain, vapour falls to the earth in different forms of sleet, snow, and hail. In the two latter states there cannot be a refraction of the rays of light; but in the former state, when a drop is partly in a congealed and partly in a fluid form, the rays of light will be differently affected, both from the form of the drop and its various refracting powers.

The halo, or corona, is a luminous circle surrounding the sun, the moon, a planet, or a fixed star. It is sometimes quite white, and sometimes coloured like the rainbow. Those which have been observed round the moon or stars are but of a very small diameter; those round the sun are of different magnitudes, and sometimes immensely great. When coloured, the colours are fainter than those of the rainbow, and appear in a different order, according to their size. In those which Sir Isaac Newton observed in 1692, the order of the colours from the inside next the sun, was in the innermost blue, white, red; in the middle purple, blue, green, yellow, pale red; in the outermost pale blue, and pale red. Huygens observed one red next the sun, and pale blue at the extremity. Mr. Weidler has given an account of one yellow on the inside, and white on the outside. In France one was observed, in which the order of the colours was white, red, blue, green, and a bright red on the outside.

Artificial coronas may be made in cold weather, by placing a lighted candle in the midst of a cloud of steam; or if a glass window is breathed upon, and the flame of a candle placed at some distance from the window, while the operator is also at the distance of some feet from another part of the window, the flame will be surrounded with a coloured halo.

The parhelia, or mock suns, are the most splendid appearances of this kind.

The parhelia generally appear about the size of the true sun not quite so bright, though they are said sometimes to rival their parent luminary in splendour. When there are a number of them, they are not equal to each other in brightness. Externally they are tinged with colours like the rainbow. They are not always round; and have sometimes a long fiery tail opposite the sun, but paler towards the extremity. Dr. Haller observed one with tails extending both ways. Mr. Weidler saw a parhelion with one tail pointing up, and another downwards, a little crooked; the limb which was farthest from the sun being of a purple colour, the other tinged with the colours of the rainbow.

Coronas generally accompany parhelia: some coloured, and others white. There is also, in general, a very large white circle, parallel to the horizon, which passes through all the parhelia; and, if it was entire would go through the centre of the sun; sometimes there are arches of smaller circles concentric to this, and touching the coloured circles which surround the sun; they are also tinged with colours, and contain other parhelia.

One of the most remarkable appearances of this kind was that which was observed at Rome by Scheiner, as intimated above; and this may serve as a sufficient instance of the parhelion.

This celebrated phenomenon is represented in fig. 10, in which A is the place of the observer, B his zenith, C the true sun, and A B a plane passing through the observer's eye, the true sun, and the zenith. About the sun C there appeared two concentric rings, not complete, but diversified with colours. The lesser of them, D E F, was fuller, and more perfect; and though it was open from D to F, yet those ends were perpetually endeavouring to unite, and sometimes they did so. The outer of these rings was much fainter, so as scarcely to be discernible. It had, however, a variety of colours, but was very inconstant. The third circle, K L M N, was very large, and entirely white, passing through the middle of the sun, and every where parallel to the horizon. At first this circle was entire; but towards the end of the phenomenon it was weak and ragged so as hardly to be perceived from M towards N.

In the intersection of this circle and the outward iris G K I, there broke out two parhelia, or mock suns, N and K, not quite perfect, K being rather weak, but N shone brighter and stronger. The brightness of the middle of them was something like that of the sun; but towards the edges they were tinged with colours like those of the rainbow, and they were uneven and ragged. The parhelion N was a little wavering; and sent out a spiked tail N P, of a colour somewhat fiery, the length of which was continually changing.

The parhelia at L and M, in the horizontal ring, were not so bright as the former, but were rounder, and white, like the circle in which they were placed. The parhelion N disappeared before K; and while M grew fainter, K grew brighter, and vanished the last of all.

It is to be observed further, that the order of the colours in the circles D E F, G K N, was the same as in the common halos, namely, red next the sun; and the diameter of the inner circle was also about 45°, which is the usual size of a halo.

Parhelia have been seen for one, two, three, and four hours together; and in North America they are said to continue some days, and to be visible from sun-rise to sun-set. When they disappear it sometimes rains, or snow falls in the form of oblong spiculæ.

Mr. Wales says, that at Churchill, in Hudson's-bay, the rising of the sun is always preceded by two long streams of red light. These rise as the sun rises; and, as they grow

longer, begin to bend towards each other, till they meet directly over the sun, forming there a kind of parhelion, or mock-sun.

These two streams of light, he says, seem to have their source in two other parhelia which rise with the true sun; and in the winter season, when the sun, never rises above the haze or fog which he says is constantly found near the horizon all these accompany him the whole day, and set with him in the same manner as they rise. Once or twice he saw a fourth parhelion under the true sun; but this, he adds, is not common.

The cause of these is apparently the reflection of the sun's light and image from the thick and frozen clouds in the northern atmosphere, accompanied also with some degree of refraction.

OR, in heraldry, denotes yellow, or gold-colour. See HERALDRY.

ORANGE. See CITRUS.

ORBICULARIS. See ANATOMY.

ORBIT. See ASTRONOMY.

ORCHARD, a plantation of fruit-trees. In planting an orchard, great care should be taken that the soil is suitable to the trees planted in it; and that they are procured from a soil nearly of the same kind, or rather poorer than that laid out for an orchard. As to the situation, an easy rising ground, open to the south-east, is to be preferred. Mr. Miller recommends planting the trees fourscore feet asunder, but not in regular rows; and would have the ground between the trees plowed, and sown with wheat and other crops, in the same manner as if it was clear from trees; by which means the trees will be more vigorous and healthy, will abide much longer, and produce better fruit. If the ground has been pasture, the green sward should be plowed in the spring before the trees are planted; and if it is suffered to lie a summer fallow, it will greatly mend it, provided it is stirred two or three times to rot the grass, and prevent the growing of weeds. At Michaelmas it should be plowed pretty deep in order to make it loose for the roots of the trees, which if the soil is dry, should be planted in October; but if it is moist, the beginning of March will be a better season.

If several sorts of fruit-trees are to be planted on the same spot, you should observe to plant the largest-growing trees backwards, and so proceed to those of less growth, continuing the same method quite through the whole plantation; by which means the sun and air will more easily pass through the whole orchard. When you have planted the trees, you should support them with stakes, to prevent their being blown out of the ground by the wind; and the following spring, if the season should prove dry, cut a quantity of green turf, and lay it about the roots, with the grass downwards; by which means a great expence of watering will be saved, and after the first year they will be out of danger. Whenever you plow the ground betwixt these trees, you must be careful not to go too deep amongst their roots which would greatly damage the trees, but if you do it cautiously, your stirring the face of the ground will be of great service to them; though you should observe never to sow too near the tree, nor to suffer any great rooting weeds to grow about them; because this would starve them, by exhausting the goodness of the soil, which every two or three years should be mended with dung or other manure. These trees, after they are planted out, will require no other pruning besides cutting off their bad branches, or such as cross each other.

ORCHIS, *fool-stones*, a genus of the gynandria diandria class of plants, the corolla of which is of a corniculated form; and its fruit is an oblong unilocular capsule, containing numerous scobiform seeds

The essential character is, nect. a horn or spur behind the flower. There are 50 species of this genus, which exceedingly resembles the ophrys.

This plant flourishes in various parts of Europe and Asia, and grows in our country spontaneously, and in great abundance. It is assiduously cultivated in the East; and the roots of it form a considerable part of the diet of the inhabitants of Turkey, Persia, and Syria. From it is made the alimentary powder called salep; which prepared from foreign roots, is sold at five or six shillings per pound, though it might be furnished by ourselves at a sixth part of that price, if we chose to pay any attention to the culture of this plant. The orchis mascula is the most valued for this purpose. A dry, and not very fertile soil, is best adapted to its growth.

ORDEAL, a form of trial, or of discovering innocence or guilt, formerly practised over almost all Europe, and which prevailed in England from the time of Edward the Confessor, till it was abolished by a declaration of Henry III. It was called purgatio vulgaris, or judicium in opposition to bellum, or combat, the other form of purgation.

In England an offender, on being arraigned, and pleading not guilty, had it in his choice to put himself upon God and his country; that is, upon the verdict of a jury; or upon God alone, on which account it was called the judgment of God, it being presumed that God would deliver the innocent. The more popular kinds of ordeal were those of red-hot iron and water: the first for freemen and people of fashion, and the last for peasants. Fire ordeal was performed either by taking up in the hand a piece of red-hot iron, of one, two, or three pounds, weight; or else by walking barefoot and blindfolded over nine red-hot ploughshares, laid at equal distances: and if the party escaped unhurt he was adjudged innocent, if not he was condemned as guilty. Water ordeal was performed either by plunging the bare arm up to the elbow in boiling water, and escaping unhurt thereby; or by casting the person suspected into a river or pond of water; and if he floated therein, without any action of swimming, it was deemed an evidence of his guilt; but if he sunk he was acquitted.

ORDER. See ARCHITECTURE.

ORDERS, or ORDINATION. No person shall be admitted to the order of deacon under 23 years of age; nor to the order of priest unless he is 24; and none shall be ordained without a title, that is, a nomination to some cure or benefice, and he shall have a testimonial of his good behaviour, for three years past, from three clergymen; and the bishop shall examine him, and if he sees cause may refuse him. And before he is ordained he shall

take the oath of allegiance and supremacy before the ordinary, and subscribe the 39 articles.

ORDINARY, in common and canon law, is one who has ordinary or immediate jurisdiction in ecclesiastical causes in such a place. In which sense archdeacons are ordinaries, though the appellation is more frequently given to the bishop of the diocese, who has the ordinary ecclesiastical jurisdiction. The archbishop is the ordinary of the whole province, to visit and receive appeals from inferior judicatures.

ORDINATES, or **Ordinate Applicates**, in geometry, are parallel lines terminating in a curve, and bisected by a diameter.

ORDNANCE, a general name for sorts of great guns used in war.

Ordnance, *office of*, an office kept within the Tower of London, which superintends and disposes of all the arms, instruments, and utensils of war, both by sea and land, in all the magazines, garrisons, and forts, in Great Britain.

ORES, metallic. This class comprehends all the mineral bodies, composed either entirely of metals, or of which metals constitute the most considerable and important part. It is from the minerals belonging to this class that all metals are extracted; for this reason they have obtained the name of ores.

As the metals at present known amount to 23, we shall divide this class into 23 orders, allotting a distinct order for the ores of every particular metal.

Metals exist in ores in one or other of the four following states: 1. In a metallic state, and either solitary or combined with each other. 2. Combined with sulphur. 3. In the state of oxides. 4. Combined with acids. Each order therefore may be divided into the four following genera:

1. Alloys. 3. Oxides.
2. Sulphurets. 4. Salts.

It must be observed, however, that every metal has not hitherto been found in all these four states, and that some of them are hardly susceptible of them all.

ORGAN, a wind-instrument blown by bellows, and containing numerous pipes of various kinds and dimensions, and multifarious tones and powers. Of all musical instruments this is the most proper for the sacred purpose to which it is most generally applied in all countries wherever it has been introduced. Its structure is lofty, elegant, and majestic; and its solemnity, grandeur, and rich volume of tone, have justly obtained it an acknowledged pre-eminence over every other instrument.

An organ, when complete, is of threefold construction, and furnished with three sets of keys; one for what is called the great organ, and which is the middle set; a second (or lower set) for the choir organ; and a third (or upper set) for the swell. In the great organ, the principal stops are the two diapasons, the principal, the twelfth, the fifteenth, the sesquialtra, the mixture or furniture, the trumpet, the clarion, and the cornet. The choir organ usually contains the stops diapason, the dulciana, the principal, the flute, the twelfth, the bassoon, and the vox humana. The swell comprises the two diapasons, the principal, the hautboy, trumpet, and cornet.

The church-organ consists of two parts; the main body, called the great organ, and the positive or little organ, which forms a small case or buffet, commonly placed before the great organ. The size of an organ is generally expressed by the length of its largest pipe: thus they say, an organ of 8, 16, 32 feet, &c. The organ in the cathedral church at Ulm in Germany is 93 feet high and 28 broad; its largest pipe is 13 inches diameter, and it has 16 pair of bellows.

ORGANIC REMAINS, or, as the science is called by some, *oryctology*. This department of natural history has of late excited an unprecedented degree of attention among the scientific; and, to the inquiring mind, does undoubtedly throw open, as it were, a new world of matter for contemplation of the most gratifying description. To pretend to enter at large on this subject, would in the present case appear presumptuous; we shall therefore merely present our readers with an abstract of it from the writings of the author of a well-known work on "The Organic Remains of a former World."

This subject, then, has reference to all those animal and vegetable substances which are dug out of the earth in a mineralized state.

In the following slight sketch of the history of these substances, it will be seen, that the remarkable situations in which they have been found, and the extraordinary changes which they have undergone, have led to the adoption of various contradictory and absurd notions respecting their nature and origin: which have been corrected, as just ideas have been obtained respecting the formation of the earth itself. Xenophanes, more than 400 years before Christ, was led to the belief of the eternity of the universe, by discovering the remains of different marine animals imbedded in rocks, and under the surface of the earth. Herodotus ascertained the existence of fossil shells in the mountains of Egypt, and was thereby induced to conclude, that the sea must have once covered those parts. In the pyramids of Egypt, mentioned by this author, and which had been built at so early a period that no satisfactory accounts could be derived from tradition respecting their erection, the stones were found to contain the remains of marine animals, and particularly of such as exist no longer in a recent state, and differ essentially from all known animals. These were supposed by Strabo, who saw the fragments of these stones lying around the pyramids, to be the petrified remains of the lentils which had been used for food by the workmen. Eratosthenes, Xanthus of Lydia, and Strabo, have all noticed and variously commented upon the existence of animal remains thus wonderfully preserved. In the works of Pliny, many fossil bodies are mentioned, particularly the bucardia, resembling an ox's heart, but which was, perhaps, a cast formed in a bivalve shell; glossopetra, bearing the form of a tongue, and supposed to fall from the moon, when in its wane; hammites, resembling the spawn of fish; horns of ammon, resembling, in form, the ram's horn; lepidotes, like the scales of fishes; meconites, bearing a resemblance to the seeds of poppies; brontia, to the head of a tortoise; spongites, to sponge; phycites, to sea-weeds or rushes, &c.

The parts of vegetables confined in subterranean situations suffer, according to cir-

cumstances, either a complete resolution of composition, the lighter parts becoming volatilized, whilst the more fixed remain, and form the substance which is termed mould (*humus*,) or, as is supposed by Mr. Parkinson, it passes through another process, which he considers as fermentative, and becomes bituminous. Wood, thus changed, is called lignum fossile bituminosum, surturbrand, and Bovey coal. By the extension of this process, the same author supposed, that the substances termed bitumens, (naphtha, petroleum, and asphaltum,) are formed. To the same process he also attributes the formation of amber, of which however no proof appears. That jet, cannel coal, and the common coal employed in domestic uses, have had a vegetable origin, is rendered highly probable, from the frequency with which they manifest the impressions of various vegetable bodies.

Thus, perhaps, the formation of the bituminous fossils may be satisfactorily explained; but by far the greater number of vegetable fossils are of a lapideous nature, and necessarily owe their formation to very different processes; which the same author supposes are, in general, preceded by the process by which bitumen is formed. Many bodies, which are evidently of vegetable origin, may be now found existing in a lapideous, either calcareous or silicious, state; and many others are found possessing certain marks of the presence of some metallic substance.

Various parts of trees and plants (*phytolithi*) are found in a mineralized state. Not only fossil wood (*lithoxylon*,) as has been just noticed, but the leaves (*lithopylla* or *lithobiblia*,) and fruits (*carpolithi*) of different trees or plants are thus found. Of the woods, several, from their form and texture, have been supposed to have been originally oak, willow, and such trees as now exist in a recent state; whilst others differ, in both these respects, from any species of wood which is now known.

The impressions of the stalks and leaves of plants are very frequently found in many parts of the world, in lofty mountains, as well as at considerable depth below the surface; and not only the impressions, but the substance itself of different vegetables are also thus found; but in no situation more frequent than in the neighbourhood of coal mines.

In general these vegetable remains are found deposited in lamina, in the schistose strata which accompany the coal; but the most perfect remains are commonly found in roundish nodular masses of ferruginous clay, which abound in the strata accompanying the coal. These are commonly termed catsheads by the workers of the coal mines, and contain pieces of fern, &c. very few, indeed, of which are found to agree with any known recent plants. One of these plants, preserved in coal slate, is shewn, plate XL and XLI, fig. I.

The remains of fruits are, perhaps, no where found so abundantly as in the Isle of Sheppey, where they are dug up in great variety; very few, however, being found which agree with any known recent fruits. Where any resemblance appears, it is with fruits which only grow in the warm Asiatic regions. Fig. 2, represents a fossil fruit which was found in the cliff of Sheppey.

Fossil roots of plants or trees are very rarely found; a circumstance not very easily explained; since they possess (especially the roots of trees) that degree of solidity which appears to be favourable to the process of petrifaction. From the want of this necessary property it undoubtedly is, that we possess so few remains of tender flower leaves, and none of pulpy fruits.

From the same cause, the great proneness to decomposition, the number of animal fossils is considerably limited: those substances being only preserved in a mineralized state which originally possessed a considerable degree of solidity; such are the bones, teeth, horns, shells, scales, &c. The animal, however, far exceeds the vegetable kingdom in the number and variety of fossils which it yields, as well as in the distinctness of form, and excellency of preservation, in which they are found.

Adopting in a great measure the arrangement of Waller, we shall commence our examination of the animal fossils with those which have derived their origin from corals. These fossils are, of course, merely the remains of the dwellings which have been formed by the various coral insects, and which are so frequently found in the cabinets of the curious.

Immediately on commencing this examination. we are struck with a similar want of agreement between the recent and fossil corals, with that which has been noticed between recent and fossil vegetables. Of the genus *tubipora* it does not appear, at least by the observations made in Mr. Parkinson's second volume of "The Organic Remains of a former World," that a single species which is known recent has been found as a fossil. Several fossil species are, however, described, of which nothing similar is known in a recent state. The most striking of these is the *tubipora catenularia*, or chain coral, the surface of which, in consequence of the tubes being in contact at their sides, has frequently a very curious reticulated or catenulated appearance. Fig. 4, represents this fossil in its usual state: and at fig. 5 is shewn the appearance of a transverse section. *Tubipora fascicularis*, *T. stellata*, *T. repens*. and *T. strues*, which have been described by different authors, and which are unlike to any known recent tubipore, give reason for supposing that the number of species of fossil tubipores exceeds that of the recent species.

The fossil madrepores are not less rich in variety, nor less comparatively numerous, than the fossils of the preceding genus. The forms of several species of the fossil madrepores do frequently approach to those of the different recent species; but in a considerable number of the fossil madrepores no resemblance is discoverable, except in their stelliform openings, with any recent coral. The madrepores consisting of a single star appear to be much more numerous in a mineral than in a recent state.

It would be useless to attempt, in this sketch, to specify the considerable variety of fossil madrepores formed of aggregated circular stars, and which have been designated as astroites, &c. Those which are composed of angulated stars are, perhaps, not so numerous: many of these, however, are very different in their appearance from those which are known in a recent state. The one most known in

these islands is the lithostrotion, sive basaltes striatus et stellatus, of Llwyd. The exact union of the sides of the polygons giving a tolerably correct idea of minute basaltes.

The millepora do not appear to be so frequently found in a mineral as in a recent state.

Of the genus isis, one species only appears to be known as a fossil. This species was first described by Scilla, who at first conjectured it to be the leg-bone of some animal. Specimens are frequently found in the Calabrian mountains, and have lately been also found in some parts of Wiltshire. Of the genus cellepora, antipathes, and gorgonia, fossil specimens appear to be rather uncommon.

The corallo fungitæ of Waller are evidently the fossil remains of alcyonia. These have been long described by Volkmann, Scheuchzer, and others, as fossil fruits, and have obtained, from their resemblance to figs, &c. the appellations of ficoides, caricoides, &c.; whilst others of a different form have been named lycoperditæ, fungitæ, pilcati, &c. A fossil alcyonium has even been described by Volkmann and Scheuchzer as a fossil nutmeg. A fossil alcyonium of a conical form is represented, fig. 6.

The encrini and pentacrini have been always, and very properly, considered as the most curious of the fossil zoophytes. The encrinus, fig. 3, possesses the distinguishing character of having its spine, or, as it has been generally called, its tail, composed of cylindrical or orbicular vertebræ, pierced through their centre, and marked with diverging striæ on their articulating surfaces.

The fossil pentacrinus differs from the encrinus, in its vertebræ being of a pentagonal form, and in its arms, fingers, and tentacula being capable of being much more widely spread and extended than are those of the encrinus.

The encrinital vertebræ, fig. 7, *a*, have been hitherto termed trochitæ when separate, and entrochi when connected in a series, fig. 7. The single vertebræ of the pentacrinus have been distinguished as asteriæ, fig. 8, *a*: and when united together they have been termed columnar asteriæ, fig. 8.

Of the asteriæ, or stellæ marinæ, some very few specimens have been found fossil; but they occur very rarely.

The fossil echini are very numerous, upwards of forty species, known only as fossils, being enumerated by the illustrious Linnæus.

An attempt to particularize the various species of fossil shells which have been found, would require a large volume: all that can be here done is to notice some of those which totally differ from any which exist in a recent state, and to offer some remarks on those which approximate, or are similar to some of the species which are known in a recent state.

With respect to the state in which fossil shells are found, it is necessary to remark, that, in some situations, shells which have been buried for ages, by the natural changes which the surface of the earth has undergone, are found very little changed, except from the loss of colour, and having been rendered extremely fragile; that in other situations the substance of the shell has been so injured as to be reduced to very small fragments, and even to a fine powder, leaving in some instances a stony, correctly moulded, cast of the cavity of the shell; that very frequently the substance of the shell is entirely altered, having become a calcareous stone, or a silicious or pyritous mass, and that the shells of a former world are frequently found in masses of marble, which is called lumachelli, or shelly marble.

Of the multivalves, the chiton does not appear to have been found in a mineralized state; and although several species of lepas have been found in a mineral state, they are by no means frequent fossils. Lepas anserifera is said to have been found fossil, as well as lepas diadema; these must, however, be exceedingly rare fossils. Fossil shells of the pholas are by no means common; the pholas crispata has been, however, found among the Harwich fossils. Fossil bivalves are very common fossils; they are, as might be expected, very seldom found in pairs, except when united by a lapideous mass, which prevents the examination of their hinge, or their internal structure, which in many fossil shells are objects highly worthy of examination.

Anomia lacunosa, fig. 9, is one of the most abundant of these species. They are found in considerable quantities in different parts of England. Anomia terebrâtula, fig. 10, is another fossil of this genus, which exists in different counties in this island, in great abundance.

Of the genus mytilus several species are known as fossils, some of which approach very near to those which are known recent: one in particular appears to differ very little indeed from mytilus modiolus. No fossil shell appears yet to have been found which can with certainty be placed under the genus argonauta. But of the genus nautilus, specimens are very frequent, fig. 11.

There are none of the fossil shells, except perhaps the anomiæ, which can vie in the variety of their species with the cornu ammonis. The cornua ammonis were formerly called serpent-stones; the appearance which they yield of a serpent coiled having led the vulgar to consider them as petrified serpents, fig. 12.

The fossil cones are very few when compared with the numerous species known in a recent state; the same may be also said of the cypræa. In both these genera the species are mostly made out more from the colour and the markings of the shells, than from the peculiarities of their form; but in the fossil shells the colours no longer exist, and of course the species in these can very seldom be presumed. The fossil volutes, as far as can be judged from their form alone, differ generally from the recent species. With respect to the genus buccinum, strombus, and murex, the number of species of the fossil shells do not appear to equal those which are known in a recent state. This is the case also, in a still greater degree, with the genus trochus. The fossil shells of the genus turbo are pretty numerous, and some of them very closely resemble those of known recent species. One fossil shell of this genus is very remarkable for its vast size, being upwards of a foot in length. The cast of another species is so large as to weigh four or five pounds.

The orthoceratites, a lapidified conical or cylindrical chambered shell, the septa dividing

the chambers of which are perforated like those of the nautilus, is a genus of which not a species is known in a recent state, excepting the microscopic specimens found by Plancus in the sand of the Riminian shore. Authors have divided them into those which are straight, fig. 13, and those which have a spiral termination, the latter of which are considered as fossil-shells of the nautilus lituus.

The belemnite, fig. 14, is a spathose radiated stone, generally conical, but sometimes possessing a fusiform figure, and contains, in an appropriate cavity at its larger end, a smaller calcareous body (*alveolus*) which has evidently been a concamerated shell, the septæ of which are pierced like those of the preceding fossil. Among the fossil-shells which can only be here enumerated, are the rare tuberculated turrilite, or chambered turbinated shell, the orbulites, planulites, and baculites of Lamarck. Insects of the smaller kinds are seldom found in a fossil state, the smallness of their size and the delicacy of their structure most probably preventing their preservation. The one, which is generally found in the most perfect condition, is that generally known to us as the Dudley fossil, from its being found in the neighbourhood of Dudley, in Worcestershire, fig. 15.

The remains of lobsters and crabs are frequently found in the isle of Sheppey, and Malta. The remains of different species of these animals are also found in a compressed state in the margaceous and schistous masses of Pappenheim and Oppenheim. The fossil remains of amphibia are very numerous, and supply us with ample exercise for inquiry and admiration. In different parts of England, particularly in Somersetshire and Dorsetshire, the remains of animals apparently of the lacerta genus are frequently found; but are, as far as we are able to judge, really different from any animal which is known to us. But in no part of the world have such exquisitely fine and wonderful remains of animals of this description been found as in St. Peter's Mountain near Maestricht.

The plates of St. Fond, as well as the specimen of professor Camper, shew that these are the remains, indubitably, of an enormous animal, different from any at present known. It must however be observed, that the remains of crocodiles, apparently of the same species which now exist, have also been discovered: part of the head of the Asiatic crocodile was found in very good preservation in the quarries of Altdorff.

Fossil fishes have been found imbedded in calcareous and argillaceous masses, in various parts of Germany, Switzerland, and Italy; but no where in such prodigious numbers as in the mountain named Vestena-Nuova, generally called Monte Bolca, in the Veronese, which extends, in height, a thousand feet above the quarry, in which are found the numerous remains of fish; of which, specimens are to be seen in almost every cabinet of repute in Europe. The remains of fishes, from an inch to upwards of three feet in length, are found in these quarries, and of these several are found whose living analogues are said to exist in the neighbourhood of Japan, and of Brasil, also in Africa and America. The Abbé Fortis is of opinion that the actual descendants of the Veronian fossil-fishes are now to be found in the sea which washes the shores of Otaheite. In Cerigo (Cytherea) Alessano, Lesina, in Dalmatia, Oeningen, Pappenheim, in Aix, and in several parts of France, fossil-fishes are found in very excellent preservation. In England, fossil-fishes are much more rarely found than in France, Germany, or Italy.

The fossil-fish of Vestena Nuova are supposed to prove, from several circumstances, that their privation of life was sudden; some having been found with the head of their prey still in their mouths; and others with the remains of the fish, which they had devoured, still in their stomachs.

The fossil remains of birds are very rarely found, though frequently mentioned, and even described by different authors. Fossils very much resembling the beaks of birds are sometimes found; but these are much more probably parts of fishes. Several of those specimens which have been spoken more positively of, as petrifactions of whole birds, and of their nests, have been merely calcareous incrustations of very modern formation. Bones very much resembling the bones of birds have been found in the calcareous stone of Oxfordshire, and in some parts of France, and of Germany.

The fossil remains of quadrupeds, especially those of the larger kind, are such as must excite the attention and wonder of every curious inquirer in natural history. In various parts of this country have been found the remains of elephants, and of other animals of considerable magnitude. In Ireland have been found the remains of deer, of a size far exceeding any now known; and in Scotland have been found the remains of the elk, as well as those of an enormous animal of the ox kind, but larger than even the urus. In France, Germany, Italy, and indeed in most parts of Europe, remains of large animals have been found, and in both North and South America, the remains of enormous unknown animals have been discovered. According to Pallas, from the Tanais to the continental angle nearest to America, there is hardly a river in this immense space, especially in the plains, upon the shores or in the bed of which have not been found the bones of elephants and of other animals not of that climate. From the mountains by which Asia is bounded, to the frozen shores of the ocean, all Siberia is filled with prodigious bones; the best ivory (fossil) is found in the countries nearest to the arctic circle, as well as in the eastern countries, which are much colder than Europe, under the same latitude; countries where only the surface of the ground becomes thawed during summer.

The number of bones which have been discovered of the rhinoceros is very considerable, not only in Siberia, but in Germany, and in other parts of Europe; and in the opinion of St. Fond, founded not only on the discoveries of Pallas and others, but on his own observations made on the immense collection of Merck, joined with that of the Langrave of Hesse Darmstadt, are of the species with double horns. An entire body of an animal of this species, still possessing the skin, fat, and muscles, has been dug up near the river Willioni, in the eastern part of Siberia, from

under a hill, which is covered with ice the greatest part of the year. St. Fond states, in confirmation of the above opinion, that another head obtained by Pallas from Siberia; one existing in the cabinet of the elector of Manheim, and another in the cabinet of Merck, are all apparently similar to the head of the double-horned rhinoceros of Africa.

Much remains to be ascertained with respect to the fossil remains of elephants, of which considerable numbers have been found in various parts of England, France, Germany, and Italy; but no where so abundantly as in Siberia. In America indeed the remains of an unknown species of this animal are also very abundant. There appear to be only two species of elephants now in existence; one (the Asiatic) being distinguished by its grinders being divided into transverse and nearly parallel plates, and the other (the African) having these plates disposed in lozenge-like forms.

The elephantine remains which have been found in Siberia have been supposed to have belonged to no existing species; for though the teeth are formed of plates disposed parallel to each other, as in the Asiatic, these plates are said to be thinner, and consequently more numerous; but this distinction is by no means established. The remains of elephants discovered in this country seem referable, in most instances, to the Asiatic.

With respect to the elephant whose remains have been found in America, the tooth of which differs essentially from all known fossil or recent species, in having its crown cuspidated and covered with enamel, fig. 16, there exists at present every reason for supposing it to be of a species now extinct. The generally adopted opinion that this animal was of a carnivorous nature is by no means established; but is indeed contradicted by the assertion that the stomach of one of these animals has been found filled with vegetable matter. One of these animals, with its flesh, skin, and hair, has been lately found in Siberia.

The remains of an animal of an enormous size has been found at Paraguay, at no great distance from the river Plata, which being properly arranged, has been formed into a skeleton, and placed in the cabinet of natural history at Madrid. This animal, twelve feet in length, and six in height, is distinguished, as well as by its general form, by the largeness of its claws; on which account, Mr. Jefferson has named it the megalonyx.

In various parts of Scotland, and of France; in Tuscany, the Veronese, and in North America, have been found the fossil remains of some animal which has been supposed to be a variety of the urus of Julius Cæsar, or of the bison. But these horns, which are of very considerable size, appear to have belonged to a different species of animal from any which is at present known. To the fossil remains already mentioned, may be added the animal incognitum of Symore, in Languedoc; the enormous stag, found in the mosses of Ireland; the gigantic tapir, found at the bottom of the black mountains of Languedoc; the bears, of two species, now unknown, found in Bareith; and the numerous animals of unknown species which the admirably indefatigable Cuvier is perpetually discovering, in that mine of fossils, the quarries of gypsum, near Paris.

Of the mineralized remains of man no well attested instance is known. In a cavern, indeed, in Mendip Hills, some human bones have been found, invested with stalactite; these appear to be but comparatively of modern existence. Scheuchzer published an essay describing a supposed skeleton of a man; which was undoubtedly the remains of some large fish.

A view of the forgeoing sketch cannot but shew, that the study of this science must prove a source of the highest gratification to every mind that contemplates the works of nature, for the purpose of obtaining a glimpse of the beauty which they display, and of the power which they manifest. By this science we obtain, not only a knowledge of the peculiar beings which dwelt on this planet in its antediluvian state, but we also acquire a more correct knowledge of the structure of this globe itself. We at the same time discover the strongest proofs of those changes which it has suffered, and which are recorded in the Holy Scriptures; whilst our reverential admiration is excited at this wonderful display of the power and providence of the Almighty Creator.

ORIBASIA, a genus of the monogynia order in the pentandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The corolla is small, tubulated, and monopetalus. The pericarpium is a globular berry, grooved longitudinally: is quinquelocular, and contains one seed. Of this there are six species, all natives of the warmer parts of America, viz. 1. Officinalis; the natives of Guiana make infusions of the leaves and give them in cases of spasmodic asthma. 2. Racemosa. 3. Violacea. 4. Lutea. 5. Paniculata. 6. Longiflora.

ORICHALCUM. See ZINC.

ORIGANUM, *origany* or *majorum*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticilatæ. There is a strobilus or cone collecting the calices together. The principal species are two hardy perennials and an annual for the open ground, and five perennials for the green house, viz. 1. The vulgare, or wild majorum. 2. The heracleoticum, or winter majorum.

ORIGENISTS, in church history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen. The Origenists maintained, that the souls of men had a pre-existent state, that they were holy intelligences, and had sinned in heaven before the body was created; that Christ is only the Son of God by adoption.

ORIGINAL, in the court of king's bench the usual original writ issued in the actions, as for action of trespass upon the case. And this court does not issue originals in actions of debt, covenant, or account, &c. whereas the court of common pleas proceeds by original in all kinds of actions; but to arrest and sue a party to outlawry, it is used in both cases.

ORIOLUS, *oriole*, in ornithology, a genus belonging to the order picæ. The bill in this genus is straight, conic, very sharp pointed; edges cultrated, inclining inwards; mandibles of equal length. Nostrils small, placed at the base of the bill and partly covered. Tongue, divided at the end. Toes three

forward, one backward; the middle joined near the base to the outmost one. These birds are inhabitants of America, except in a few instances; they are a noisy and gregarious, frugivorous, granivorous, and voracious race, very numerous, and often have pessile nests. The several species, which are very numerous, since Mr. Latham describes no less than forty-five, seem to be principally distinguished by their colour.

ORION, in astronomy, a constellation of the southern hemisphere, consisting of thirty-seven stars, according to Ptolemy; of sixty-two according to Tycho; and of no less than eighty, in the Britannic catalogue.

ORNITHOGALUM, *star of Bethlehem*, a genus of the hexandria monogynia class of plants, the corolla whereof consists of six petals, of a lanceolated figure from the base to the middle erect, from thence to the points, plano-patent; they are permanent, but lose their colour; the fruit is a round angulated capsule, formed of three valves, and containing three cells; the seeds are numerous and roundish, the receptacle columnar. There are thirty-five species, all of them herbaceous and perennial, rising from three to six feet high, having stalks terminated with long spikes of hexapetalous, star-shaped, white and yellow flowers.

ORNITHOLOGY, that branch of natural history which considers and describes birds, their natures and kinds, their form, external and internal, and teaches their economy and uses; see AVES: also the several orders and genera in the alphabetical order. Birds are divided, according to the form of their bills, into six orders, viz. *accipitres*, as eagles, vultures, and hawks: *picæ*, as crows, jackdaws, humming-birds, and parrots: *anseres*, as ducks, geese, swans, gulls: *graliæ*, as herons, woodcocks, and ostriches: *gallinæ*, as peacocks, pheasants, turkies, and common fowls; and *passeres*, comprehending sparrows, larks, swallows, &c.

ORNITHORYNCHUS *paradoxus* from New South Wales, a singular quadruped, which has not yet been properly classed in the Linnæan system. The most remarkable circumstance in this curious animal, is the great similarity of its head with that of a duck, which however, is still more striking in its internal structure. From the external form of the scull of this animal, one might be more easily led to conclude that it belonged to such an aquatic bird, than to a creature of the mammalia tribe. Both the jaws are as broad and low as in a duck, and the calvaria has no traces of a suture, as is generally the case in full grown birds. There is likewise a singularity in the cavity of the scull, of which nothing like it is known in any quadruped animals of the mammalia, though there exists something analogous in the class of birds, namely, a considerable bony falx, which is situated along the middle of the os frontis, and the ossa bregmatis. This processus is in general scarcely to be seen in the mammalia, even in those that have a bony tentorium cerebelli. The mandible of this animal is very singular, consisting of a beak, the under part of which has its margin indented as in ducks, and of the proper instrument for chewing that is situated behind, within the cheeks. This has no teeth, nor even the traces of alveoli, but only two broad processes of a peculiar formation on each side, whose undulated superficies fit one another. Dr. Shaw says of the specimen he examined, that it had no teeth, "dentium nulla sunt vestigia." But Sir Joseph Banks informs us that Mr. Home has found in a specimen that belongs to the Society of Natural History at Newcastle, on each side of the jaws, two small and flat molar teeth. The fore part of this anomalous mandible, or the beak, is covered and bordered with a coriaceous skin, in which three parts are to be distinguished: 1. The proper integument of the beak (integumentum rostri.) 2. The labiated margins of it (margines labiales.) 3. A curious edge of the skin of the beak (limbus transversarius.)

ORPHAN. In the city of London there is a court of record established for the care and government of orphans.

ORPIMENT is a fine yellow powder, formed from a solution of the white oxide of arsenic in muriatic acid, to which is added a solution of sulphuretted hydrogen in water. It may also be obtained by subliming arsenic and sulphur by a heat not sufficient to melt them. It is likewise found native in many parts of Germany and Italy, composed of plates that have a considerable degree of flexibility.

ORRERY, a curious machine for representing the motions and appearances of the heavenly bodies. See PLANETARIUM.

ORTHOGRAPHY, that part of grammar which teaches the nature and affections of letters, and the just method of spelling or writing.

ORTHOGRAPHY, in geometry, the art of drawing or delineating the fore right plan of any object, and of expressing the heights or elevations of each part. It is called orthography, from its determining things by perpendicular lines falling on the geometrical plane.

ORTHOGRAPHY, in architecture, the elevation of a building.

ORTHOGRAPHY. See PERSPECTIVE.

OTTOLAN. See EMBERIZA.

ORYZA, *rice*, a genus of the digynia order, in the hexandria class of plants; and in the natural method ranking under the 4th order, gramina. The calyx is a bivalved uniflorous glume; the corolla bivalved, nearly equal, and adhering to the seed. There is but one species, namely, the sativa or common rice. This plant is greatly cultivated in most of the Eastern countries, where it is the chief support of the inhabitants; and great quantities of it are brought into England and other European countries every year, where it is much esteemed for puddings, &c. it being too tender to be produced in these northern countries without the assistance of artificial heat; but from some seeds which were formerly sent to Carolina there have been great quantities produced, and it is found to succeed there as well as in the Eastern countries.

OSCILLATION, in mechanics, the vibration, or reciprocal ascent and descent, of a pendulum. See PENDULUM.

It is demonstrated, that the time of a complete oscillation in a cycloid, is to the time in which a body will fall through the axis of that cycloid, as the circumference of a circle to its diameter; whence it follows, 1. That

the oscillations in the cycloid are all performed in equal times, as being all in the same ratio to the time in which a body falls through the diameter of the generating circle. 2. As the middle part of the cycloid may be conceived to coincide with the generating circle, the time in a small arch of that circle will be nearly equal to the time in the cycloid; and hence the reason is evident, why the times in very little arches are equal. 3. The time of a complete oscillation in any little arch of a circle, is to the time in which a body would fall through half the radius, as the circumference of a circle to its diameter; and since the latter time is half the time in which a body would fall through the whole diameter, or any chord, it follows that the time of an oscillation in any little arch, is to the time in which a body would fall through its chord, as the semicircle to the diameter. 4. The times of the oscillations in cycloids, or in small arches of circles, are in a sub-duplicate ratio of the lengths of the pendulums. 5. But if the bodies that oscillate are acted on by unequal accelerating forces, then the oscillation will be performed in times that are to one another in the ratio compounded of the direct subduplicate ratio of the lengths of the pendulums, and inverse subduplicate ratio of the accelerating forces. Hence it appears that if oscillations of unequal pendulums are performed in the same time, the accelerating gravities of these pendulums must be as their lengths; and thus we conclude, that the force of gravity decreases as you go towards the equator, since we find that the lengths of pendulums that vibrate seconds are always less at a less distance from the equator. 6. The space described by a falling body in any given time, may be exactly known; for finding by experiments, what pendulum oscillates in that time, the half of the pendulum will be the space required, in the duplicate ratio of the diameter of a circle to the circumference.

OSCILLATION, *Centre of.* See CENTRE.

OSIER, a very valuable shrub, of the salix viminales, used principally in basket-making.

OSMAZOME. If cold water which has been digested for a few hours on slices of raw muscular fibre, with occasional pressure, be evaporated, filtered, and then treated with pure alcohol, a peculiar animal principle will be dissolved, to the exclusion of the salts. By dissipating the alcohol with a gentle heat the osmazome is obtained. It has brownish-yellow colour, and the taste and smell of soap. Its aqueous solution affords precipitates, with infusion of nut-galls, nitrate of mercury, and nitrate and acetate of lead

OSMIUM. See CHEMISTRY.

OSSIFICATION. The deposition of calcareous phosphate or carbonate on the soft solids of animal bodies; as in the pineal gland, lungs, liver, &c.

OSTEOLOGY. See ANATOMY.

OSTEOSPERMUM, a genus of the class and order syngenesia polygamia necessaria. "The cal. is simple, in two rows, many-leaved, almost equal; seeds globular, coloured, bony; down none; recept. naked. There are seventeen species, shrubs of the Cape.

OSTRACION, in ichthyology, a genus of the branchiostegous order of fishes, of a globose, oval, or ovato-quadrangular figure: the skin is always very firm and hard; and is in some species smooth, in others entirely covered with spines; and finally, in some the spines entirely occupy only particular places; there are no belly-fins, and the others are five in number, viz. two pectoral or lateral fins, one on the back, the pinna ani, and the tail. There are 12 species of this genus. the triqueter has a triangular body unarmed; inhabits India; the back appearing as if covered with rhombic marks cut transversely. The quadricornus, with frontal and subcaudal spines, inhabits India and Guinea.

OSTRACION, trunk-fish, a genus of fishes, of the order nantes; the generic character is, teeth pointing forwards, cylindric rather blunt; body mailed by a bony covering.

OSTREA, the *oyster,* in zoology, a genus belonging to the order of vermes testaceæ. The shell has two unequal valves; the cardo has no teeth, but a small hollowed one with transverse lateral streaks. There are thirty-one species, principally distinguished by peculiarities in their shells. The common oyster is reckoned an excellent food; and is eaten both raw and variously prepared. The character of the genus, in the words of Barbut, is, "The animal a tethys; the shell bivalve, unequivalve, with something like ears; the hinge void of teeth, with a deep oval hole, and transverse streaks on the sides. There is no womb nor anus." The genus is divided into four families, of which ostrea is the last.

The oyster differs from the muscle in being utterly unable to change its situation. It is entirely without a tongue, which answers the purposes of an arm in the other animal, but nevertheless is often attached very firmly to any object it happens to approach.

Oysters usually cast their spawn in May, which at first appears like drops of candle-grease, and sticks to any hard substance it falls upon. These are covered with a shell in two or three days; and in three years the animal is large enough to be brought to market. As they invariably remain in the places where they are laid, and as they grow without any other seeming food than the afflux of sea-water, it is the custom at Colchester, and other parts of England, where the tide settles in marshes on land, to pick up great quantities of small oysters along the shore, which, when first gathered, seldom exceed the size of sixpence. These are deposited in beds where the tide comes in, and in two or three years grow to a tolerable size. They are said to be better tasted for being thus sheltered from the agitations of the deep; and a mixture of fresh water entering into these repositories, is said to improve their flavour, and increase their growth and fatness. The oysters, however, which are prepared in this manner, are by no means so large as those found sticking to rocks at the bottom of the sea, usually called rock-oysters. These are sometimes found as broad as a plate, and are admired by some as excellent food. But what is the size of these compared to the oysters of the East Indies, some of whose shells have been seen two feet over! The oysters found along the coast of Coromandel, are capable of furnishing a plentiful meal for eight or ten men; but it seems universally agreed that they are no way comparable to ours for delicacy of flavour

OSTRICH See STRUTHIO.

OTIS, the *bustard*, in ornithology, a distinct genus of birds, of the order of the gallinæ, the characters of which are these: there are three toes on each foot, all turned forwards; and the head is naked, or has no comb. There are four species, principally distinguished by their colour. One of the species, the tarda, or bustard, (see plate Nat. Hist. fig. 309,) is the largest of the British land fowl, the male at a medium weighing 25 pounds; there are instances of some very old ones weighing 27; the breadth nine feet; the length near four. Besides the size and difference of colour, the male is distinguished from the female by a tuft of feathers about five inches long on each side of the lower mandible. Its neck and head are ash-coloured; the back is barred transversely with black and bright rust-colour; the greater quill-feathers are black; the belly white; the tail is marked with broad red and black bars, and consists of twenty feathers; the legs dusky. The female is about half the size of the male: the crown of the head is of a deep orange, traversed with black lines; the rest of the head is brown. The lower part of the fore side of the neck is ash-coloured; in other respects it resembles the male, only the colours of the back and wings are more dull. The birds inhabit most of the open countries of the south and east parts of this island, from Dorsetshire as far as the Wolds in Yorkshire. Bustards lay only two eggs of the size of those of a goose, of a pale olive brown, marked with spots of a dark colour; they make no nest, only scrape a hole in the ground. In autumn they are (in Wiltshire) generally found in large turnip-fields near the downs, and in flocks of 50 or more.

OTTER. See MUSTELA.

OVAL, an oblong curvilinear figure, otherwise called ellipsis. The proper oval, however, or egg-shape, differs considerably from that of the ellipsis, being an irregular figure, narrower at one end than at the other; whereas the ellipsis, or mathematical oval, is equally broad at each end; though it must be owned, these two are commonly confounded together, even geometricians calling the oval a false ellipsis.

OVERSEERS *of the poor*. By 43 Elizabeth, c. 2, § 1, the churchwardens of every parish, or two substantial householders, to be nominated yearly in Easter week, or within one month after Easter, under the hand and seal of two justices of the peace of the county, shall be overseers of the same parish. In general, all persons are liable to serve, with some exceptions as to peers of the realm, clergymen, parliament men, attornies, practising barristers, the president and members of the college of physicians, surgeons, and apothecaries free of the hall; dissenting ministers, prosecutors of felons, having a Tyburn ticket, and soldiers actually serving in the militia. Their duty consists in raising the poors'-rate, taking care of the poor, giving relief to casual poor, and removing persons who come to settle in a tenement under 10*l.* a year, &c. without a certificate. They are also to bind out the children of poor persons, and in that case the infant parish apprentice and his master cannot vacate the indentures without the overseers. They are also to procure orders of maintenance of bastards to be made, and bonds to be taken from the reputed father to indemnify the parish.

OVERT ACT. In the case of treason in compassing or imagining the death of the king, this imagining must be manifested by some open act; otherwise being only an act of the mind it cannot fall under any judicial cognizance. Bare words are held not to amount to an overt act, unless put into writing, in which case they are then held to be an overt act, as arguing a more deliberate intention. No evidence shall be admitted of any overt act, that is not expressly laid in the indictment. 7. W. c. 3.

OVIS, *sheep*, a genus of quadrupeds of the order pecora; the generic character is, horns hollow, wrinkled, turning backwards, and spirally intorted; front teeth, eight in the lower jaw; canine-teeth, none.

O. aries, or the common sheep. This animal, in its state of complete domestication, appears equally stupid as it is harmless, and seems nearly to justify the observations of Buffon, who describes it as one of the most timid, imbecile, and contemptible of quadrupeds. When sheep, however, have an extensive range of pasture, and are left in a considerable degree to depend upon themselves for food and protection, they exhibit more respectability of character. A ram has been seen in these circumstances to attack and beat off a large and formidable dog, and even a bull has been felled by a stroke received between his eyes, as he was lowering his head to receive his adversary on his horns and toss him into the air. When individual efforts are unequal to the danger, sheep will unite their exertions, placing the females and their young in the middle of an irregular square, the rams will station themselves so as to present an armed front on every side to the enemy, and will support their ranks in the crisis of attack, harassing the foe by the most formidable and sometimes fatal blows. Sheep display considerable sagacity in the selection of their food, and in the approach of storms they perceive the indications with accurate precision, and retire for shelter always to the spot which is best able to afford it. The domestic sheep is scarcely ever found (excepting in temperate latitudes) in a state approaching to perfection. In hot regions its wool degenerates into a species of hair, and in rigid climates, though the wool is fine at the roots, it is coarse towards the surface.

Of all the domestic animals, none is so subject to various disorders as the sheep. Of these, one of the most extraordinary, as well as the most fatal, is the rot, owing to vast numbers of worms, of the genus fasciola, which are found in the liver and gall-bladder. They are of a flat form, of an oval shape, with slightly pointed extremities, and bear a general resemblance to the seeds of a gourd.

OUNCE, a little weight, the sixteenth part of a pound avoirdupois, and the twelfth part of a pound troy; the ounce avoirdupois is divided into sixteen drams, and the ounce troy into twenty pennyweights.

OUNCE. See FELIS.

OUTLAWRY, is being put out of the law, or out of the king's protection. It is a punishment inflicted for a contempt in refusing to be amenable to the process of the higher courts. By outlawry in civil actions, a person is put out of the protection of the law, so that he is

not only incapable of suing for the redress of injuries, but may be imprisoned, and forfeits all his goods and chattels, and the profits of his land; his personal chattels immediately upon the outlawry, and his chattels real, and the profits of his lands, when found by inquisition.

OUTWORKS, in fortification, all those works made withoutside the ditch of a fortified place, to cover and defend it. See Fortification.

OX. See Bos.

OXALATES, are compounds of the salifiable bases with oxalic acid.

OXALIC ACID. This acid, which abounds in wood sorrel, and which, combined with a small portion of potash, as it exists in that plant, has been sold under the name of *salt of lemons*, to be used as a substitute for the juice of that fruit, particularly for discharging ink-spots and iron-moulds, was long supposed to be analogous to that of tartar.

In the year 1776, however, Bergmann discovered, that a powerful acid might be extracted from sugar by means of the nitric; and a few years afterwards Scheele found this to be identical with the acid existing naturally in sorrel. Hence the acid began to be distinguished by the name of *saccharine*, but has since been known in the new nomenclature by that of oxalic.

The oxalic acid is a good test for detecting lime, which it separates from all the other acids, unless they are present in excess. It has likewise a greater affinity for lime than for any other of the bases, and forms with it a pulverulent insoluble salt, not decomposable except by fire, and turning syrup of violets green. Oxalic acid acts as a violent poison when swallowed in the quantity of 2 or 3 drachms; and several fatal accidents have lately occurred in London, in consequence of its being improperly sold instead of Epsom salts. Its vulgar name of salts, under which the acid is bought for the purpose of whitening boot-tops, occasions these lamentable mistakes. But the powerfully acid taste of the latter substance, joined to its prismatic or needle-formed crystallization, are sufficient to distinguish it from every thing else. The immediate rejection from the stomach of this acid by an emetic, aided by copious draughts of warm water containing bicarbonate of potash, or soda, chalk, or carbonate of magnesia, are the proper remedies.

OXIDATION. The process of converting metals or other substances into oxides, by combining with them a certain portion of oxygen. It differs from *acidification* in the addition of oxygen not being sufficient to form an acid with the substance oxided.

OXIDES. Substances combined with oxygen, without being in the state of an acid.

OXYGEN GAS. This gas was obtained by Dr. Priestley in 1774 from red oxide of mercury exposed to a burning lens, who observed its distinguishing properties of rendering combustion more vivid and eminently supporting life. Scheele obtained it in different modes in 1775; and in the same year Lavoisier, who had begun, as he says, to suspect the absorption of atmospheric air, or of a portion of it, in the calcination of metals, expelled it from the red oxide of mercury heated in a retort. Oxygen gas forms about a fifth of our atmosphere, and its base is very abundant in nature. Water contains 88,88 per cent. of it; and it exists in most vegetable and animal products, acids, salts, and oxides. See Chemistry.

OXYMEL, is a compound of honey and vinegar.

OXYMURIATIC ACID, or Chlorine. See Chemistry.

OYER *of a deed*, in law, is when a man brings an action upon a deed, bond, &c. and the defendant appears and prays that he may hear the bond, &c. wherewith he is charged; and the same shall be allowed him. And he is not bound to plead till he has it, paying for the copy of the instrument. It is then set forth upon the pleadings.

Oyer and **Terminer**, in law, is a court by virtue of the king's commission, to hear and determine all treasons, felonies, and misdemeanors. This commission is usually directed to two of the judges of the circuit, and several gentlemen of the county; but the judges only are of the quorum, so that the rest cannot act without them.

Oyer *of the records*, in law, is a petition made in court, that the judges for more satisfactory proof, will be pleased to hear or look upon any record.

O YES, corrupted from the French *oyez*, hear ye, is an expression used by the crier of a court, in order to enjoin silence, when any proclamation is made.

OYSTER. See Ostrea.

P.

P, or p, the fifteenth letter, and eleventh consonant of the alphabet. In music, P. stands for piano, or softly; P P. for piu piano, *i. e.* more softly; and P P P. for pianissimo, or very softly.

Among astronomers, P. M. is used to denote post meridian, or afternoon; and sometimes for post mane, *i. e.* after midnight.

As a numeral, P. signifies the same as G, *viz*, 400; and with a dash over it, thus P̄. 400,000.

Among physicians, P. denotes pugil, or the eighth part of an handful; P. Æ. partes æquales, or equal parts of the ingredients; P. P. signifies pulvis patrum, *i. e.* the Jesuit's powder; and ppt. præparatus, prepared.

PACE, a measure taken from the space between the two feet of a man, in walking, usually reckoned two feet and an half, and in some men a yard or three feet. See Measure.

The geometrical pace is five feet; and 60,000 such paces make one degree of the equator.

PACK, in commerce, denotes a quantity of goods made up in loads or bales for carriage. A pack of wool is 17 stone and two pounds, or a horse's load.

PACKERS, persons whose employment it is to pack up all goods intended for exportation; which they do for the great trading

companies and merchants of London, and are answerable if the goods receive any damage through bad package.

PACOS. See CAMELUS.

PÆONIA, *peony*, a genus of the digynia order, in the polyandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. The calyx is pentaphyllous; the petals five; there are no styles; the capsules are polyspermous. There are five species, most of them hardy; they are large herbaceous flowery perennials, with tuberous roots, sending up strong annual stalks from one to three feet in height, terminated by very large flowers of a beautiful red colour, and much larger than any rose. The common officinal, or male peony, is also remarkable for its capsules turning backward, opening and displaying their red inside, together with the numerous seeds in a singularly agreeable order, appearing very ornamental after the flower is past.

PAGANISM, the religion of the Heathen nations, in which the Deity is represented under various forms, and by all kinds of images, or idols; it is therefore called idolatry, or image worship. The theology of the Pagans was of three sorts, *viz.* fabulous, natural, and political or civil. The first treats of the genealogy, worship, and attributes of their deities; who were, for the most part, the offspring of the imagination of poets, painters, and statuaries. To their gods were given different names and opposite attributes, ascribing to them every species of vice, as well as to [illegible] very vir

PAGE, a youth of state retained in the family of a prince or great personage, as an honourable servant, to attend in visits of ceremony, carry messages, bear up trains, robes, &c. and at the same time to have a genteel education, and learn his exercises.

PAGOD, or PAGODA, a name whereby the East Indians call the temple, in which they worship their gods. The pagod usually consists of three parts: the first is a vaulted roof, supported on stone or marble columns; it is adorned with images; and, being open, all persons without distinction are allowed to enter it. The second part is filled with grotesque and monstrous figures, and no person is allowed to enter it but the brahmins themselves. The third is a kind of chancel, in which the statue of the deity is placed. It is shut up with a very strong gate.

PAGOD, or *Pagoda*, is also the name of a gold or silver coin, current in several parts of the East Indies, value 5*s*.

PAINTING, is the art of representing all objects of nature visibly, by lines and colours on a plain surface. It has also the power of expressing by the same means conceptions and images of the mind which do not actually exist in any of the usual forms of nature. It is to be considered as an art displaying either conjointly or separately the powers of imagination and imitation: and may be divided into invention, which regards the original thought or conception of the subject; and into composition, design, and colouring, which regard the execution of the work.

Invention consists generally in the choice of such subjects as are best calculated to answer some great and interesting end; and particularly in discovering or selecting such subjects as are capable of being most appropriately expressed by painting, and of producing a powerful effect by such means as are distinctively placed within the compass of that art.

Composition regards the arrangement of the subject both as to forms, and to the general effects of light and shade, and of colour. It comprehends the general distribution and grouping of the figures, their combination or contrast, the choice of attitudes, the disposal of draperies, the situation of the scene itself, as well as the distribution and connection of all the various parts of scenery and ornament.

Design.—Although this part of the art is, in a certain degree, requisite even in making the first rough sketch, it is not until afterwards that the artist exerts his utmost powers to give that exact proportion, that beauty of contour, and that grace and dignity of action and deportment to his figures, which constitute the perfection of *design*. The most perfect knowledge of form, however, is not the only branch of painting, termed design. The art of *foreshortening*, by which a limb or a figure, although only occupying a diminished space on the canvas, is rendered in appearance of its full length and magnitude, is an equally indispensable object of the artist's attainment.

Colouring regards, first, the infinite variety of hues with which nature distinguishes her forms, agreeably to the degree and mixture of the rays of light which their surfaces reflect; and, secondly, the distribution, apposition, and accompaniment, of various hues or tints, so as to produce the effect most pleasing to the sight, a circumstance in which nature always delights.

Colouring.—It is the duty of the colourist to consider, that as there are two sorts of objects, the natural or real, and the artificial or painted, so there are also two sorts of colours, viz. the natural, or that which makes all the objects in nature visible to us, and the artificial, or that, which, by a judicious mixture of simple colours, imitates those natural ones in all their various situations and circumstances.

Of the few maxims which can be offered on the subject of colouring, the following are the least questionable:

We must learn to view nature to advantage, in order to represent her well. There are two manners of colouring; the one depending on habit, the other on the true knowledge of colours. The first is confined, the second unlimited.

The harmony of nature in her colours arises from objects participating of one another by reflection; for there is no light which does not strike some body; nor is there any enlightened body which does not reflect its light and colour at the same time, in proportion to the force of the light, and according to the nature of the colour. This participation of reflection in light and colour, constitutes that union of colouring which it is the business of the painter to imitate.

Variety of tints, very nearly of the same tone, employed in the same figure, and often upon the same part, with moderation, contribute much to harmony.

Any loading or overcharging of colouring, for whatever purpose it is used, must be so discreetly managed, as not to destroy the character of the object.

The repetition of the same colour in a picture is to be avoided, unless where it serves to connect the various masses of a composition. The eye becomes tired with viewing the same object; it loves variety artfully presented to it.

The apparent value of colours in a picture (as in all things) arises from comparison.

Several colours which, placed unmixed by one another, have a kind of aerial brightness, when mixed together, produce a disagreeable earthy colour: for instance, ultramarine with fine yellow, or fine vermilion.

Colours which by mixture lose strength and become harmonious, are called broken colours, and contribute as greatly to the sweetness and softness of tones in pictures as they subtract from their brightness.

Chiaro Scuro.

The art of chiaro-scuro consists, 1st. In connecting and combining the figures or objects of a composition in such masses of light and of shade, as are both the most pleasing to the eye and the best calculated for the just developement and display of the subject. 2dly. In assigning to each object the colour most corresponding (on account of the force or qualities above mentioned) to its respective place in the general mass or group, and at the same time best harmonizing with the other colours of the picture, either by its natural and proper tone, or by the reflected hues which it receives from adjoining or surrounding objects. The beauty of these reflexes depends on the skilful adaptation of transparent or opaque colours. 3rdly. In the judicious introduction of such accidents as contribute to strengthen the general effect and character of the work. It is on chiaro-scuro, says Mengs, that depends the expression of the character of a picture, whether it is gay or gloomy, cheerful or solemn The distribution of objects forms the masses of chiaro-scuro, by combining or connecting their lights and shades in such a manner as to prevent the eye from wandering confusedly over the work.

Composition.

Composition may be divided into the general distribution of objects, the grouping, the choice of attitudes, the contrast, the cast of draperies, and the management of the back ground, or the connection of the whole effect.

In composition, as far as regards the general distribution of objects, the painter ought to contrive that the spectator may, at the first sight, be struck with the general character of the subject, or at least may comprehend its principal scope. This effect is most readily produced by placing the most essential figures in the most conspicuous places, provided it can be done without violence or impropriety. Besides this distinctness in the general expression of the subject, the beauty of the composition will depend on the variety, connection, and contrast, displayed in the distribution of objects; provided, in like manner, that these are conformable to the nature of the subject, whether gay, familiar, full of motion and hurry, or still, solemn, and melancholy.

The grouping regards both design and chiaro-scuro. In the former, it respects the figures principally concerned in the expression of the subject, which must necessarily be near to, or distant from one another, as their actions, conversations, or other mutual relations, require. In the latter, it regards those masses which are formed from objects which may be properly arranged together, and those effects of light and shade which are formed in consequence of such assemblage or union. These are the points to which the attention must be principally and diligently directed in forming the groups of a composition. The choice of attitudes is the principal subordinate division of grouping. Whatever attitude is given, it must not only contribute its due portion to the completion of the group, but the greatest care must be taken by the painter, that it does not appear to be introduced for that purpose merely. It must be appropriate to the character of the individual figure, and expressive of its requisite action: and it must at the same time, combine whatever beauty of form can be shewn by such a selection of turns or views of the body, as the necessary circumstances will admit. The knowledge of generic characters, under the various modifications of sex, age, and condition; of the various operations of the passions in the human mind; and a thorough acquaintance with the circumstances of the history or other subjects to be represented; are the best guides to a good choice of attitudes The management of the back-ground, or connection of the general effect, is effected by a due combination of lights and shades, by an union of colours, and by such oppositions or contrasts as are sufficient to relieve the distinct groups, and to give repose to the eye.

The different classes of painting.

Painting is chiefly divided into historical (comprehending allegorical and mystical,) grotesque, portrait, fancy, animals, fruits and flowers, battles, landscape, sea-views, architecture, still life. The subordinate divisions of all these are endless. The first has been sufficiently spoken of under the head of *invention,* in the present article.

Grotesque paintings are to be found in the celebrated Loggia of the Vatican palace at Rome, painted from the designs of Raffaelle and in the ceiling of the portico of the Capitol, carved from those of Michael Angelo. Of portrait, as being a branch of painting much cultivated in our country, it is requisite to give a more detailed account.

Portraiture. The greatest perfection of a portrait is extreme likeness, and the greatest fault is the resemblance of a person for whom it was not designed, unless we are inclined to except a still more grievous defect, *viz.* the want of resemblance to any person whatever.

Various difficulties attend, and not seldom impede, the execution of this task. It is true that there is not a single person in the world of whatever age, sex, or condition, who has not a peculiar character both in body and face; but it is also the essential duty of portraiture, that it not only imitates what we see in nature, but that it exhibit such views of nature as are confessedly the most advantageous to the person represented. The moment that the idea raised by the sight of the portrait is inferior to that raised by the sight of the person, the labour of the artist sinks into the debasing region of caricature. The resemblance, as well as every other excellence, of a portrait, depends on feature, expression, air, colouring, attitude

and attire. The features require to be carefully examined and studied by inspection in many different views, so that at the moment when the painter puts his pencil to the canvas, he may be possessed not only of the apparent form of each particular feature, in the view in which he represents it, but of its real and characteristic form also, the full expression of which is not discernible in every view. Each particular feature should appear so distinctly shaped, as that an exact model of the real head could be formed from the picture, if requisite; and they must be at the same time so blended in the general mass of the face, that no one shall obtrude itself on the eye beyond the rest. The peculiar mode of touch, or execution, whereby each feature is best discriminated, can only be learned from practice, and the attentive study of the best masters.

With regard to the methods of proceeding in the execution of a portrait, they have been, and are, so exceedingly various, in various masters, that a discussion of them would lead to an endless labyrinth.

Nothing varies more quickly, more discernibly, or more frequently, than the colour of a sitter's face. Great care must therefore be taken to establish an uniform judgment of the sitter in this respect also; for the colouring of the skin, or complexion being an effusion of nature, tending to discover the true tempers of persons, exactness of imitation here becomes essential to the exhibition of character. It may be therefore expedient to watch the first moments of the appearance of colour in the sitter, who, sooner or later, from a continuance in one posture, loses those spirits, which, at his first sitting down, gave to every part of the face a livelier and fresher hue. There is no other point of painting in which the paradox may be more truly asserted, "that the painter, who only paints what he sees, will never arrive at perfect imitation."

The other classes of painting are sufficiently denoted by their names, excepting the last, viz. *still life*, of which it may by requisite to add that the term is applied to all inanimate objects, but chiefly to all household furniture, ornaments, and instruments of use, &c.

Modes and Materials of Painting.

The different modes of painting now in use are:

Oil painting; preferable to all other methods, as it admits of a perfect gradation of tints in the most durable of all materials, except those of Mosaic painting; in which an imitation of objects is produced by the junction of a great number of small pieces of natural marble of different colours fixed in stucco, a mortar, so that if the mortar is well prepared, the monuments of this art may descend to the most remote ages.

Fresco painting; which is performed with colours diluted in water, and laid on a wall newly plastered with which they incorporate, and are sometimes as durable as the stucco itself.

Crayon painting; in which colours, either simple or compound, are ground in water mixed with gum, and made into small rolls of a hard paste, which are then used on paper or parchment.

Miniature painting; which consists of colours prepared with water or gum, and laid on vellum or ivory.

Enamel painting; which is performed on copper or gold, with mineral colours, dried by fire. This method is also very durable.

Wax, or encaustic painting; performed by the mixture of wax with the varnish and colours.

Painting on glass, is too well known to need description, and performed by various methods.

Painting in distemper; which is with colours mixed with size, whites of eggs or any thin glutinous substance, and used on paper, linen, silk, board, or wall.

Painting in water-colours, more properly called limning; it is performed with colours mixed with water, gum, size, paste, &c. on paper, silk, and various other materials.

To these is to be added elydoric painting, consisting of a mixed use of oil colours and water.

Painting in Fresco.

Before you begin to paint, it is necessary to apply two layers of stucco on the place where your work is to be executed. If you are to paint on a wall of brick, the first layer is easily applied; if of free-stone closely joined, it is necessary to make excavations in the stone, and to drive in nails or pegs of wood, in order to hold the layer together.

The first layer is made of good lime and a cement of pounded brick, or which is better, river-sand, which latter forms a layer more uneven, and better fitted to attach the second smooth layer to its surface. The ancients appear to have possessed the art of making this species of mortar superior to any now in use.

Before applying the second layer, on which you are to paint, it is requisite that the first be perfectly dry, as the lime while moist emits a pernicious effluvium.

When the first layer is perfectly dry, wet it again with water, in proportion to its dryness, that the second layer may more easily incorporate with it.

The second layer is composed of lime, slaked in the air, and exposed for a whole year, and of river-sand of an equal grain, and moderately fine. The surface of this second layer must be uniformly even. It is laid on with a trowel; and the workman is provided with a small piece of wood, to remove the large grains of sand, which if they remained, might render the surface uneven.

To give a fine polish to this surface, a sheet of paper should be applied on it, and the trowel passed and repassed over the paper; this caution will prevent any little inequalities which might injure the effect of the painting at a distance.

The workman must not extend the layer over a greater space than the painter is able to finish in a day, as it is necessary that the ground should always be fresh and moist under his pencil; and it is on this account that the readiness of the artist's hand becomes so requisite a quality in the execution of works in fresco.

The ground being thus prepared, the painter begins his work; but as painting in fresco must be executed rapidly, and as there is no time to retouch any of the strokes of the brush with good effect, he will first have taken care to provide himself with large finished drawings in chalk or paintings in distemper, of the same size as the work which he has to paint, so that he shall

have only to copy these drawings on the wall. The painter traces the outlines of the figures on the plaister, by passing a steel point over them, or pricking them closely and passing very finely powdered charcoal through the pricked holes. All natural earths are good for painting in fresco. The colours are ground and tempered with water. It is to be remarked, that all the colours used in this method of painting brighten as they grow dry, excepting the pavonazzo or red varnish, the brownish red ochre, ruth ochre, and the blacks, particularly those that are passed through the fire. The best colours are white, made of old lime, and white marble-dust (the proportional quantity of the latter depends on the quality of the lime, and must be found by trial, as too great a quantity of marble-dust will turn the colour black; ultramarine blue, the black of charcoal, yellow ochre, burnt vitriol, red earth, green of Verona, Venetian black, and burnt ochre. Other colours which require to be used with greater precaution, are amel, or enamel blue, and cinnabar. Enamel blue must be applied instantaneously, and while the lime is very moist, otherwise it will not incorporate; and if you retouch with it, you must do it in an hour or more after the first application of it, in order to increase its lustre. Cinnabar has a splendour almost beyond all other colours, but it loses it when mixed with lime. It may, however, be employed in places not exposed to the air, if proper care is used in preparing it. For this purpose, reduce a quantity of the purest cinnabar to powder, put it into an earthen vessel, and pour lime water on it two or three times. By this process the cinnabar receives some impression from the lime water, and you may then use it with greater safety. The white of lime is formed by mixing lime, slaked a long time before with good water. The lime deposits a sediment at the bottom of the vessel; when the water is poured off, this sediment is the white of lime. Another kind of white may likewise be made from egg shells, pounded, in great quantities, and boiled in water, together with quick lime, and afterwards put into a strainer and washed repeatedly with spring water. The shells must be again pounded until the water employed for that purpose becomes pure and limpid; and when the shells are completely reduced to powder, they are ground in water made up in small pieces and dried in the sun. The effect of this colour must be ascertained by experiment. Ochres of all kinds make good colours for fresco, being previously burnt in iron boxes. Ultramarine never changes, and seems to communicate its permanent quality to the colours with which it is mixed.

Distemper.

In addition to what has been said of this method of painting under its proper article, the following particulars are worthy of notice:

Until the discovery of oil-painting, the methods most generally adopted by all Italian painters were those of distemper and fresco.

In distemper, when they painted on boards, they often pasted over the boards a piece of fine cloth, to prevent them from parting; they then laid on a layer of white, after which, having tempered their colours with water and paste (or rather with water and yolks of eggs beat together with little fig tree branches, the milk of which mixed with the eggs) they painted their pictures with this mixture. All colours are proper for distemper, except the white of lime, which is used in fresco only. Azure and ultramarine must be used with a paste made of gloveskin, or parchment, as they will turn green when mixed with yolks of eggs. If the work is on walls, care must be taken that they are quite dry. The painter must even lay on two layers of hot paste before he applies the colours, which, if he pleases, he may also temper with paste; the composition of eggs and fig-tree branches being only retouching, and the paste rendering the work more durable. When used, it must be kept hot by fire. This paste, as has been said, is made of glove-skin or parchment.

When a painter in distemper would work on cloth, he must choose that which is very old and smooth.

Oil painting.

The principal advantage of oil-painting over other methods consists in the colours drying less speedily, so that it allows the painter to finish, smooth, and retouch his works, with greater care and precision. The colours also being more blended together, produce more agreeable gradations, and a more delicate effect.

As the superior beauty of oil painting depends on the vividness and delicacy of durable tints, we shall present the student with the best rules drawn from a careful study of the works of Vandyck and Rembrandt, two of the most remarkable colourists in different styles.

Of painting flesh.

Flake-white is the best white known to us. This colour should be ground with the finest poppy-oil that can be procured.

White comes forward to the eye with yellows and reds, but retires with blues and greens. It is the nature of all whites to sink into whatever ground they are laid on, therefore they should be laid on white grounds.

Ivory-black is the best black: it is a colour which mixes kindly with all the others. It is the true shade for blue; and when mixed with a little Indian red, it is the best general shadow-colour that can be used. It is generally ground with linseed oil, and used with drying oil.

Black is a cold, retiring colour.

Ultramarine is the finest blue in the world: it is a tender retiring colour, and never glares, and is a beautiful glazing colour. It is used with poppy-oil.

Lake is a tender deep red, but of no strong body; therefore, it should be strengthened with Indian red. It is the best glazing colour that can be used. It is ground with linseed-oil, and used with drying oil.

Burnt umber is a fine warm brown, and a good working strong colour: it is of great use in the hair, and mixes finely with the warm shade.

Process. The process of oil-painting, particularly in the colouring of flesh and in landscape, is to be divided into three stages, or paintings.

The colours and tints necessary for the first and second stages of painting flesh, are: 1. Flake, or fine white; 2. Light ochre and its

tints; 3. light red and its two tints; 4. vermilion and its tint; 5. a tint composed of lake, vermilion, and white; 6. rose tint; 7. blue tint; 8. lead tint; 9. green tint; 10. half-shade tint, made of Indian red and white; 11. shade tint; 12. red shades; 13. warm shade.

The finishing palate for a complexion requires five more, viz. 1. carmine and its tint; 2. lake; 3. brown pink; 4. ivory-black; 5. Prussian blue.

First stage, or dead-colouring of flesh.

The first lay of colours consists of two parts; the one is the work of the shadows only, and the other that of the lights.

The work of the shadows is, to make out all the drawing very correctly with the shade tint, in the same manner as if it was to be done with this colour only, and remember to drive or lay the colour sparingly. The lights should be all laid in with the light red tint, in different degrees, as we see them in nature.

These two colours united, produce a clean, tender, middle tint. In uniting the lights and shades, you should use a long softener, about the size of a large swan-quill, which will help to bring the work into character, and leave the colouring more delicate, then go over the darkest shadows with the red or warm shade, which will finish the first lay.

The warm shade being laid on the shade tint, improves it to a warmer hue; but if laid instead of the shade tints, it will spoil the colours it mixes with; and if the red shade is laid first, instead of the shade tint, the shadows would then appear too red: therefore, notwithstanding these two colours are the best that can be for the shadows, yet they are too strong to be laid alone, which is a proof of the great use and merit of the shade tint. Here we may observe that the shade and light-red tints are so friendly in their nature, that even in continually altering and changing, they always produce a clean colour of a pearly hue.

Next. In order to finish the first painting, improve the reds and yellows to the complexion, and after them the blues; observing, that the blues on the reds make the purple, and on the yellows produce the green. The same method is to be understood of the shadows: but be sure to leave them clean, and not too dark; therefore, allowance should be made in the grounds with the light red, because glazing them will make them darker. When the cloth is of a dark, or bad colour, there must be a strong body of colour laid all over the shadows, such as will not sink into the ground, but appear warm, and a little lighter than the life, so that it may be of the same forwardness to finish as if it had been a light ground; therefore, the business of dead-colouring is, that you leave it always in the same order for finishing, though the colour of the cloth is quite the reverse.

Second painting, or second stage.

The second painting begins with laying on the least quantity that can be of poppy-oil; then wipe it almost all off with a dry piece of a silk handkerchief.

The second painting is also divided into two parts: one, the first lay of the second painting; which is scumbling the lights, and glazing the shadows: the other, finishing the complexion with the virgin tints, and improving, as far as you can, without daubing.

First. Scumbling is going over the lights, where they are to be changed, with the light red tints, or some other of their own colours, such as will always clear and improve the complexion, with short stiff pencils; but such parts only as require it, otherwise the beauty of the first painting will be spoiled.

The light red tint improved is the best colour for scumbling, and improving the complexion in general. Where the shadows and drawing are to be corrected, you should do it with the shade tint, by driving the colour very stiff and bare, that you may the easier retouch and change it with the finishing tints. Some parts of the shadows should be glazed with some of the transparent shadow-colours, such as will improve and come very near to the life; but be sure not to lay on too much of it, for fear of losing the hue of the first painting, the ground of which should always appear through the glazing. Be very careful in uniting the lights and shades, that they do not mix dead and mealy; for the more the lights mix with the shades, the more mealy those shades will appear. Thus far the complexion is prepared and improved, in order to receive the virgin tints.

Second. Go over the complexion with the virgin tints. These are the colours which improve the colouring to the greatest perfection, both in the lights and shadows.

This should be done in the same manner as you laid them in the second part of the first painting; that is, with the reds, yellows, and blues, blending them with delicate light touches of the tender middle tints without softening. Leave the tints and their grounds clean and distinct, and be content to leave off whilst the work is safe and unsullied, leaving what is farther required for the next sitting; for, in attempting the finishing touches before the other is dry, you will lose the spirit and drawing, and your colours will become of a dirty hue.

Third painting, or finishing.

It is to be supposed, the complexion now wants very little more than a few light touches; therefore there will be no occasion for oiling.

Begin with correcting all the glazing; first, where the glazing serves as a ground or under part; then determine what should be done next, before you do it, so that you may be able to make the alteration on the part with one stroke of the pencil. By this method you preserve both the glazing and the tints; but, if it happens that you cannot lay such a variety of tints and finishing colours as you intended, it is much better to leave off while the work is safe and in good order; because those few touches, which would endanger the beauty of the colouring, may easily be done, if you have patience to stay till the colours are dry; and then, without oiling, add those finishings with free light strokes of the pencil.

Of painting draperies.

In order to shew the nature and different degrees of colours or tints used in painting draperies, we must first determine how many divisions are absolutely necessary to make the first lay of colours, and after that the reflections and finishing tints.

The right method of painting draperies in

general is to make out the whole, or the first lay, with three colours only, viz. the lights, middle tint, and shade tint.

The reflections of draperies and satins are generally productions of their own, and are always lighter than the shadows on which they are found; and being produced by light, will consequently have a light warm colour, mixed with the local colour that receives them. Here it will be necessary to notice the general method of managing the colours of the first lay, and those of the reflections and finishing tints.

In the first lay, the high lights should be laid with plenty of stiff colours, and then shaped and softened into character with the middle tint very correctly. Where the gradations of the lights are slow, as in the large parts, it will be proper to lay the middle tint first at their extremities with a tool that will drive the colour, and leave it sparingly; because the lights will mix and lie the better upon it. Next make out all the parts of the shadows with the tint driven bare. After this comes the middle tint, for the several lights and gradations; which should be very nicely wrought up, to character, without touching any of the high lights which finish the first lay.

The reflects and finishing tints are in general the antipathies of the first lays; they will, without great care, dirty the colours on which they are laid; and therefore should be laid with a delicate light touch, without softening. If it is overdone, endeavour to recover it with the colour of the part on which it was laid, this may be done directly, or when it is dry. Whether the reflects proceed from the same colour, or any other, the method of using them is the same.

Before we proceed to the particular colours, it will be proper to make some observations on their grounds.

It often happens, that the colour of the cloth is very improper for the ground of the drapery; and when it is so, you should change it with those colours which are most proper to improve and support the finishing colours. This method of dead-colouring must consequently preserve them in the greatest lustre. In dead-colouring, you should lay the lights and shades in a manner so as only to shew a faint idea of them, with regard to the shape and roundings of the figure. If you have a design to work from, then it will be proper to make all the large and principal parts in their places, which should always be done with a colour that is clean and lighter than the intended drapery, though in general of the same hue; and let the shadows be no darker than a middle tint. These should be mixed and broken in a tender manner, and then softened with a large tool, so that nothing rough and uneven is left to interrupt or hurt the character of the finishing colours.

White satin. All whites should be painted on white grounds, laid with a good body of colour, because this colour sinks more into the ground than any other.

There are four degrees of colours in the first lay, to white satin. The first is the fine white for the lights; the second is the first tint, which is made of a fine white and a little ivory-black, mixed to an exact middle degree between the white and the middle tint. This colour follows the white; and it is with this you should shape the lights into character before you lay on any other: and take care that this first tint appears distinctly between the white and the middle tint, otherwise the beauty and the character of the satin will be spoiled.

The middle tint should be made of white, black, and a little Indian red. These three colours are very friendly, and mix to a beautiful clear colour of a pearly hue, which has the true brightness and warmth of the general hue of the satin. Remember to allow for the red hue changing a little to the lead. If there is occasion to make any part in the middle tint lighter, do it with the first tint only.

A little blue is sometimes used in the first tint of white satin.

Changeable colours. Changeable colours are made with four principal tints, viz. the high lights, middle tint, shade tint, and reflecting tint.

The greatest art lies in finding the exact colour of the middle tint, because it has more of the general hue of the silk than any o[illegible]e others. The shade tint is of the same hue with the middle tint, though it is dark enough for the shadows. The high lights, though often very different from the middle tint, should be of friendly-working colour, that will, in mixing with it, produce a tint of a clean hue.

The method of painting silks is to make out the folds with the shade tint, and then fill them up in the lights with the middle tint. This first lay should be done to your satisfaction before you add any other colours; and the stiffer the middle tint is used, the better the high lights may be laid upon it. The reflecting tint falls generally upon the gradating half shades, and should be laid with tender touches sparingly, for fear of spoiling the first lay.

This method of painting answers for all coloured silks, as well as changeable, with this difference only; that the plain colours require not so much art in matching the tints, as the changeable do. The last part of the work is the finishing and strengthening the shadows with an obscure tint, a little inclining to a mellowish hue; such as will not catch the eye, and interrupt the beauty of the lights.

Black. The best ground for black is light red for the lights, and Indian red and a little black for the shadows.

The finishing colours are, for the lights, black, white, and a little lake. The middle tint has less white, and more lake and black: the shade tint is made of an equal quantity of lake and brown pink, with a very little black.

The method of painting black is very different from that of other colours; for as in these the principal thing is to leave their lights clear and brilliant, so in black it is to keep the shadows clear and transparent. Therefore, begin with the shade tint, and glaze over all the shadows with it. Next, lay in the darkest shadows with black, and a little of the shade tint, very correctly. After that, fill up the whole breadth of lights with the middle tint only. All which should be done exactly to the character of the satin, velvet, cloth, &c. &c. and then finish with the high lights.

Here observe, the ground, being red, will bear out and support the reds, w[illegible]h are used in the finishing colours. The lake in the lights takes off the cold hue, and gives it a more beautiful colour. If the shade tint was of any other colour than a transparent warm hue, the sha

dows would consequently be black and heavy: because no other colours can preserve the warm brilliancy which is wanting in the shadows of the black, like lake and brown pink. Black is of a cold heavy nature, and always too strong for any other colour; therefore you should make an allowance in using it. There will be a few reflects in satin, which should be added as those of other colours; but they should be made of strong colours, such as burnt umber, or brown ochre, mixed with a little shade tint.

Though the grounds mentioned for the draperies are absolutely necessary for the principal and nearest figures in a picture, such as a single portrait, or the like; yet for figures which are placed behind the principal or front figures, their grounds should always be fainter in proportion to their local finishing colours.

Linen. The colours used in linen are the same as those in white satin, except the first tint, which is made of white and ultramarine ashes, instead of the black, and mixed to a very light bluish tint.

In the dead-colouring, take particular care that the grounds are laid very white and broad in the lights.

Of painting back-grounds.

The principal colours that are necessary for painting of back-grounds, as walls, buildings, or the like, are white, black, Indian red, light and brown ochre, Prussian, and burnt umber; from which the eight principal tints are made, as follows:

1. Pearl is made of black, white, and a little Indian red.
2. Lead, of black and white, mixed to a dark lead-colour.
3. Yellow, of a brown ochre and white.
4. Olive, of light ochre, Prussian, and white.
5. Flesh, of Indian red and white, mixed to a middle tint.
6. Murrey, of Indian red, white, and a little black, mixed to a kind of purple, of a middle tint.
7. Stone, of white, umber, black, and Indian red.
8. Dark shade, of black and Indian red only.

Here the lead tint serves for the blues, the flesh tint mixes agreeably with the lead, and the murrey is a very good blending colour, and of great use where the olive is too strong; the umber, white, and dark shade, will produce a fine variety of stone colours; the dark shade and umber, used plentifully with drying oil, make an excellent warm shadow-colour. All the colours should be laid with drying oil only, because they mix and set the better with the softener.

Where the marks of the trowel are so strong in the priming of the cloth, that one body of colours will not be sufficient to conceal it, lay a colour to prevent it, which should be dry before you begin with those parts you expect to finish at once painting.

Process. The process of painting back-ground is divided into two parts in stages; the first is the work of the first lay, the second that of the finishing tints.

Begin the first lay from the shadowed side of the head, and paint the lights first; from them go into the gradations and shadows, which should be done with a stiffish tool, very sparingly, with the dark shade and white, a little changed with the colours that will give it more of the required hue, but very near in regard to tone and strength, leaving them like mezzotinto.

The dark and warm shadows should be laid before the colours that join them. This do with the dark shade and umber, driven with drying oil. If those colours were laid on first, they would spoil the transparency, which is their greatest beauty The more the first lay is driven, the easier and better you may change it with the finishing tints, therefore you may lay them with the greater body.

The second part is to follow directly, whilst the first lay is wet, with those tints that are the most proper to harmonize and finish with.

Begin with the lights first, and remember, as you heighten and finish them, to do it with warmer colours; and let those be accompanied with fine tender cold tints. The lightest parts of the ground should be painted with a variety of light warm clear colours, which vanish and lose their strength imperceptibly in their gradations. Take care that you do not cover too much of the first lay, but consider it as the principal colour.

From the lights, go to the gradations and shadows; for when the lights are well adapted to produce and support the figure, it is easy to fall from them into whatever kind of shadows you find most proper; then soften and blend the whole with a long large hog-tool; which, with the strength and body of the drying oil, will melt and sweeten altogether, in such a manner as will seem surprisingly finished. Remember the tints will sink, and lose a little of their strength and beauty in drying. All grounds, as walls, &c. should be finished at once painting; but if they want to be changed, glaze them with a little of the dark shade and drying oil, driven very bare; on which, with a few light touches of the colour that is wanting, you may improve their hue. The dark shadows may also be strengthened and improved by glazing, which should be done after the figures are nearly finished, for fear of making them too strong.

Curtains should be dead-coloured when we paint the ground; and should be done with clean colours, of a near hue to the intended curtain, such as will support the finishing colours; do it with a tender sort of keeping, and near in regard to their tone in the lights, but much softer in the shadows: all which should be mixed and broken with the colours of the ground.

It will often happen, that we cannot make the folds the first painting; we should then leave the masses of light and shadow, in regard to the keeping of the picture, broad and well united together, such as may seem easy to finish on. The colours of the landscape, in back-grounds, should be broken and softened also with those of the parts which join them. This method will make all the parts of the ground, as it were, of one piece.

The sky should be broke with the lead and the flesh-tints. The murrey-tint is of great use in the grounds of distant objects; and the umber and dark shades in the near grounds. The greens should be more beautiful than you intend them, because they will fade and grow darker. After all is painted, go over the whole very lightly with the softener, as you did the

grounds, which will make it look agreeably finished.

Of Landscape Painting.

The principal colours used in landscapes are; 1. Flake white; 2. White lead, or common white; 3. Fine light ochre; 4. Brown ochre; 5. Brown pink; 6. Burnt umber; 7. Ivory black; 8. Prussian blue; 9. Ultramarine; 10. Terreverte; 11. Lake; 12. Indian red; 13. Vermilion, or native cinnabar; 14. King's yellow.

The principal tints are, 1. Light ochre and white; 2. Light ochre, Prussian blue, and white; 3. Light ochre, and Prussian blue; 4. The same darker; 5. Terreverte and Prussian blue; 6. Brown pink and Prussian blue; 7. Brown pink and brown ochre; 8. Brown pink, ochre, and Prussian blue; 9. Indian red and white; 10. Ivory-black, Indian red, and lake.

The colours necessary for dead-colouring, are: common white, light ochre, brown ochre, burnt umber, Indian red, ivory black, and Prussian blue.

The principal colours and tints for painting the sky, are, fine white, ultramarine, Prussian blue, light ochre, vermilion, lake, and Indian red.

The tints are, a fine azure, lighter azure, light ochre and white, vermilion and white and a tint made of white, a little vermilion, and some of the light azure, at your discretion.

Process.—Sketch or rub in your design faintly, with burnt umber used with drying oil, and a little oil of turpentine: leaving the colour of the cloth for the lights. Remember, in doing this, to leave no part of the shadows so dark as you intend the first lay or dead-colouring, which also is to be lighter than the finishing colours. Though the foliage of the trees is only rubbed in faintly, yet the trunks and bodies should be in their proper shapes, with their breadths of light and shadow. All kind of buildings should be done in the same manner, leaving the colour of the cloth for their lights. The figures on the fore-ground may also be sketched in the same manner, and then left to dry.

First Painting or Dead-colouring,

Let the first lay, or dead-colouring, be without any bright, glaring, or strong dark colours; so that the effect is made more to receive and preserve the finishing colours, than to shew them in their first painting.

The sky should be done first, then all the distances; and so work downwards to the middle group, and from that to the fore-ground, and nearest parts. Remember, all the parts of each group, as trees, buildings, or the like, are all painted with the group they belong to.

The greatest secret in dead-colouring is, to find the two colours which serve for the ground of shadows in general, the sky excepted; and the method of using them with the lights: the first of which is the dark shade with a little lake in it; the other colour is only burnt umber. These should be a little changed to the natural hue of the objects, and then laid on with drying oil, in the same manner as we shade with Indian ink, which is a kind of glazing, and as such they should be left; otherwise they will be dark and heavy, and therefore would be entirely spoiled for the finishing glazing. Both these colours mix and sympathize agreeably with all the lights, but should be laid before them.

The sky.—The sky should be laid with a good body of colours, and left with a faint resemblance of the principal clouds, more in the manner of claro obscure than with finishing colours; the whiter it is left, the better it will bear out and support them. The distances should be made out faint and obscurely, with the dark shades, and some of their lights in different degrees, and laid so as best to find and shew their principal parts. All the grounds of the trees should be laid or rubbed in, enough only to leave an idea of their shapes and shadows faintly. The ground of their shadows must be clean, and lighter than their finishing colours.

In painting the lights, it is better to incline more to the middle tint than to the very high lights; and observe to leave them with a sufficient body of clean colours, which will preserve the finishing colours better; all which may be done with a few tints. After this, go over the whole with a sweetener very lightly, which will soften and mix the colours agreeably for finishing.

Second Painting.

Begin with the sky, and lay in all the azure and colours of the horizon; then soften them; after that, lay in the general tint of the clouds, and finish on it with the high lights, and the other tints that are wanting, with light tender touches; then soften the whole with a sweeterer very lightly. The finishing of the sky should be done all at one painting, because the tender character of the clouds will not do so well as when the whole is wet. Observe, that the stiffer the azure and colours of the horizon are laid, the better the clouds may be painted upon them.

The greatest distances are chiefly made with the colour of the sky; as they grow nearer and darker, glaze and scumble the parts very thin, with such glazing shadow colours as come nearest to the general hue of the group the objects are in. This glazing should be understood of a darkish hue; and that the first painting or dead-colour should be seen through it distinctly. On this lay, or ground, add the finishing colours.

Third and last Painting.

If oiling is necessary, lay the least quantity that can be; which should be done with a stump tool or pencil, proportioned to the place that is to be oiled, so as to oil no more than is wanted: then wipe the whole place that is oiled, with a piece of silk handkerchief.

When going to finish any objects, remember to use a great variety of tints, very nearly of the same colour, but most of all when finishing trees. This gives a richness to the colouring, and produces harmony. The greens will fade, and grow darker; therefore it is highly necessary to improve and force them, by exaggerating the lights, and making a[illegible]lowance in using them so much the lighter. [illegible]or the same reason, take great care not to overcharge and spoil the beauty of the glazing; for if you do it will be dull and heavy, and will consequently grow darker

The method of painting near trees is, to make the first lay very near to nature, though not quite so dark, but more in the degree of a middle tint, and follow it with strengthening the shadows; then the middle tints; and last of all lay the high lights and finishing colours. All this cannot be done as it should be at one painting; therefore the best way is, to do no more than the first lay with the faint shadows, and leave it to dry.

Then begin with improving the middle tints and shadows, and let them dry.

The third and last work is, adding all the lights and finishing colours in the best manner you are able. This method of leaving the first and second parts to dry separately, not only makes the whole much easier, and more agreeable, but leaves the colours in the greatest perfection; because most of the work may be done with scumbling and glazing, and some parts without oiling. The lights also may be laid with a better body of colour, which will not be mixed and spoiled with the wet ground.

The figures in the landscape are the last work of the picture; those in the fore ground should be done first, and those in the distances should be done next; for after the figures in the first and farthest group are painted, it will be much easier to find the proportions of those in the middle parts of the picture. And observe, that the shadows of the figures should be of the same hue, or colour, with those of the group or place they are in.

Miniature Painting.

Miniature painting is of very ancient date, and is practised either on vellum or ivory; the colours are prepared with water, or gum. It is of all others the most delicate and tedious in its process, being performed wholly with the point of the pencil. It is only fitted for works of a small size, and must be viewed near.

Colours used in Miniature Painting.

In painting the face, the yellows that are used are five, viz. gall-stone, terra Sienna, Nottingham ochre, Roman ochre, and Naples yellow; the latter three of which are opaque colours, the other transparent. The greens are confined to one, which is sap-green. The blues are verditer, Prussian, indigo, smalt, ultramarine, and Antwerp. The reds are, carmine, drop lake, Chinese vermilion, and Indian red. Under the class of reds, may also be put burnt terra Sienna, its colour inclining much that way, though more to the orange. The only browns, if any are used in the face, are burnt umber and terra de Cassel, and they are only to be used in the mixture of dark shades.

For painting draperies, we shall only add to the above colours, lamp-black, king's-yellow, and flake-white.

From the variety of style adopted by different miniature painters, it is very difficult for a young beginner to ascertain which is best to be followed; and as there is a certain degree of mechanical attention to be paid to the management of the water colours, to preserve them clear and free from muddiness, which is difficult to attain, we recommend to the young artist to procure a good miniature, if possible, and keep it by him, observing the style of pencilling and management of the colour, at the same time letting nature be his guide in the marking of his features and colouring of his picture.

In the management of back grounds, the young painter is to observe their two-fold purpose: that of giving the lights their proper value; and on the other hand, of harmonizing the colours of the face, by artfully engaging the eye with somewhat of similitude in the back-ground to a tint in the face, which otherwise, in course of working to express a particular part, might appear too prevalent.

In painting a head, on an oval piece of ivory, such as the present form of a miniature picture, draw the chin as nearly as possible in the centre of the ivory, unless the person is very tall, in which case it must be higher up; and if very short, the contrary.

Mosaic Painting.

This wonderful branch of art, improperly called painting, almost defying the hand of time, has been practised in many countries; but the finest works of their kind, and those by which the moderns have retrieved the art, which was in a manner lost, are those in the church of St. Agnes, formerly the temple of Bacchus, at Rome, at Pisa, Florence, and other cities of Italy.

The most esteemed among the works of the moderns are those of the church of St. Peter, at Rome. There are also very good ones at Venice.

Mosaic work is composed of small pieces of glass, marble, precious stones, &c. of various colours, cemented on a ground of stucco or mortar, in imitation of painting. It is generally employed in copying original pictures of the highest value in the art.

In performing this work, it is requisite to provide little pieces of glass of as many different colours as can possibly be got.

For this purpose a glass-maker's furnace being prepared, and the pots and crucibles full of the matter of which glass is made, put into each crucible what colour you require, always beginning with the weakest, and augmenting the strength of the colour from crucible to crucible till you come to the deepest tincture.

When the glass has been thoroughly concocted, and the colours are in their perfection, take out the glass, hot as it is, and pour it on a smooth marble, flatting it down with another similar marble, and then cut it into slices of equal sizes, and about the thickness of an inch and a half.

Then with an instrument, which the Italians call bocca di cane, you must make some pieces square, and others of different forms and sizes, as occasion requires. These pieces are to be orderly disposed in cases, as in painting in fresco. It is usual to range all the different tints in shells, and according to their colour

If it is desired to have gold, either in the ground of the painting, or in the ornaments or draperies, take some of the pieces of glass, formed and cut in the manner before mentioned; moisten these on one side with gum-water, and afterwards lay them over with leaf-gold; then put this piece, or several pieces at a time, on a fire-shovel, and place it in the mouth of a furnace, after you have first covered them with another hollow piece of glass.

Let these stand till they are just red-hot, then draw the shovel out all at once, and the gold will become so firmly attached to the glass, that it will never afterwards come off.

Now in order to apply these several pieces, and out of them, to form a picture, in the first place provide a cartoon or design, as this is to be transferred to the ground or plaster by calking, as in painting in fresco. See FRESCO.

As the plaster is to be laid thick on the wall, and therefore will continue fresh and soft for a considerable time, there may be enough prepared at once to serve for as much work as will take up three or four days.

This plaster is composed of lime made of hard stone, with brickdust very fine, gum tragacanth, and whites of eggs; and having been thus prepared and laid on the wall, and the design of what is to be represented transferred to it, take out the little pieces of glass with a pair of pliers, and range them one after another, still keeping strictly to the light shadow, different tints and colours which are to be represented; pressing or flatting them down with a ruler, which serves both to sink them within the ground, and to render the surface even.

A long time and tedious labour are requisite to finish the work, which will be more beautiful as the pieces of glass are more uniform and ranged at an even height.

Pieces of mosaic work performed with exactness appear as smooth as a table of marble, and as finished and masterly as a painting in fresco, with this advantage, that they have a fine lustre, and will last for ages.

Mosaic Work of Marble, and precious Stones.

These two kinds of mosaic bear so near a resemblance to each other, as to the manner of working, that to avoid repetition, we shall give them both under one, taking notice as we proceed, wherein the one differs from the other, either in the sawing or the ranging of the stones.

Mosaic work of marble is used in large works, as in pavements of churches and palaces, and in the incrustation and veneering of the walls of edifices of the same kind.

Mosaic of precious stones is only used in small works, as ornaments for altar-pieces, tables for cabinets, &c. on account of the exceeding price of the materials.

Process of Mosaic Painting.

The ground of mosaic works wholly marble, is usually a massive marble, either white or black.

On this ground the design is cut with a chisel, after it has been first chalked.

After it has been cut of a considerable depth, *i. e.* an inch or more, the cavities are filled up with marble of a proper colour, (first selected according to the colours of the design, or original picture to be copied,) and reduced to the thickness of the indentures with various instruments.

To make the pieces thus inserted into the indentures cleave fast, (whose several colours are to imitate the tints of the original design,) a stucco is composed of lime and marble-dust, or a kind of mastic, which is prepared by each workman after a different manner peculiar to himself.

The figures being marked out, the painter or sculptor himself draws with a pencil the colours of the figures not determined by the ground, and in the same manner makes strokes or hatchings in the place where shadows are to be; and after he has engraven with the chisel all the strokes thus drawn, he fills them up with a black mastic, composed partly of Burgundy pitch poured on hot, taking off afterwards what is superfluous with a piece of soft stone or brick, which, together with water and beaten cement, takes away the mastic, polishes the marble, and renders the whole so even that one would imagine it only consisted of one piece.

This is the kind of mosaic work that is seen in the church of the Invalids in Paris, and the chapel at Versailles, and with which some entire apartments of that palace are incrustated.

As for mosaic work of precious stones, other and finer instruments are required than those used in marble, as drills, wheels, &c. used by lapidaries, and engravers on stone.

As none but the richest marbles and stones are used in this work, to make them go the further they are sawn into the thinnest slices or coats imaginable, scarce exceeding half a line in thickness: the block to be sawn is fastened firmly with cords on the bench, and only raised a little on a piece of wood one or two inches high.

Two iron pins, which are on one side of the block, and which serve to fasten it, are put into a vice contrived for the purpose; and with a kind of saw or bow, made of fine brass wire bent on a piece of spungy wood, together with emery steeped in water, the slice is gradually fashioned by following the stroke of the design made on paper, and glued on the piece.

When there are pieces enough fastened to form any one entire part of the design, they are applied to the ground.

The ground which supports this mosaic work is usually of free-stone.

The matter with which the stones are joined together is a mastic, or a kind of stucco, laid very thin on the slices of marble, &c. as they are fashioned; this being done, the slices are applied with pliers; and if in any part they are not either square or rounded sufficiently, so as to fit the place exactly into which they are to be inserted, they are brought down, when too large, with a brass file or rasp; and when too little, a drill, and other instruments, used by lapidaries, are used to supply the deficient part.

PAKFONG. The white copper of the Chinese, said to be an alloy of copper, nickel, and zinc; in 16 parts of which there are 7 of zinc, 2½ of copper, and 6½ of nickel. The combination of zinc and nickel simply does not succeed.

PALÆSTRA, in Grecian antiquity, a public building, where the youth exercised themselves in wrestling, running, playing at quoits, &c.

PALAMEDEA, a genus of birds belonging to the order of grallæ. The character of this genus is, the bill bends down at the point with a horn, or with a tuft of feathers erect near the base of it; the nostrils are oval; the toes are divided almost to their origin, with a small membrane between the bottoms of each.

PALATE. See ANATOMY.

PALATINE COUNTIES, are those of Chester, Durham, and Lancaster.

PALE, a little pointed stake or piece of wood, used in making inclosures, separations, &c. The pale was an instrument of punishment, and execution, among the ancient Romans, and still continues so among the Turks. Hence, empaling, the passing a sharp pale up the fundament through the body.

Pale, in heraldry, one of the honourable ordinaries of an escutcheon; being the representation of a pale or stake placed upright, and comprehending the whole height of the coat from the top of the chief to the point.

PALISADE, or **Palisado**, in fortification, an inclosure of stakes or piles driven into the ground, each six or seven inches square, and eight feet long, three whereof are hidden under ground. Palisadoes are generally used to fortify the avenues of open forts, gorges, half-moons, the bottoms of ditches, the parapets of covert ways, and in general all posts liable to surprise, and to which the access is easy.

PALLADIUM. See Chemistry.

PALLET, among painters, a little oval table, or piece of wood, or ivory, very thin and smooth; on, and round which, the painters place the several colours they have occasion for, to be ready for the pencil. The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but instead thereof a hole at one end to put the thumb through to hold it.

Pallet, among potters, crucible makers, &c. a wooden instrument, almost the only one they use, for forming, beating, and rounding their works; they have several kinds: the largest are oval, with a handle; others are round, or hollowed triangularly; others, in fine, are in manner of large knives, serving to cut off whatever is superfluous on the moulds of their work.

Pallet, in gilding, an instrument made of a squirrel's tail, to take up the gold leaves from the pillow, and to apply and extend them on the matter to be gilt. See Gilding.

Pallet, in heraldry, is nothing but a small pale, consisting of one half of it in breadth, and therefore there are sometimes several of them upon one shield.

Pallet is also a part belonging to the balance of a watch or movement. See Watch.

PALM, a measure in length of about three inches.

PALMÆ, in botany, *palms*. Under this name Linnæus has arranged several genera, which he has placed apart in an appendix to the work. The same plants constitute one of the seven families or tribes into which all vegetables are distributed by Linnæus in his "Philosophia Botanica." They are defined to be plants with simple stems, which, at their summit, bear leaves resembling those of the ferns, being the composition of a leaf and a branch; and whose flowers and fruit are produced on that particular receptacle, or seat, called a spadix, protruded from a common calyx in form of a sheath or scabbard, termed by Linnæus "spatha."

PANAX, **Ginseng**, a genus of the diœcia order, in the polygamia class of plants. In the umbel the corolla is five-petalled; stamina five; hermaphrodite calyx five-toothed; superior styles two; berry two-seeded; male calyx entire. There are nine species of this plant: 1. Quinquefolia; 2. Trifolia; 3. Fruticosa; 4. Arborea; 5. Spinosa; 6. Aculeata; 7. Chrysophylla; 8. Simplex; 9. Attenuata.

PANCRATIUM, a genus of the hexandria monogynia class of plants, the flower of which consists of six lanceolated petals; its nectarium is twelve-cleft; stamina placed on the nectary There are ten species, beautiful flowering plants, with large bulbs.

PANCREAS. See Anatomy.

PANDANUS, a genus of the diœcia monandria class and order. There is no calyx or corolla; male anther sessile; female stigmas two; fruit compound. There is one species.

PANDECTS, in the civil law, collections made by Justinian's order of 534 decisions of the ancient lawyers, on so many questions occurring in the civil law; to which that emperor gave the force and authority of law, by an epistle prefixed to them The pandects consist of fifty books, and make the first part of the body of the civil law.

PANEL, in law. See Jury.

PANICUM, a genus of the digynia order, in the triandria class of plants. The calyx is trivalved, the third valvule being very small. The species are in number seventy-nine, grasses of different countries.

PANNEL, in law. In the Scotch law, pannel signifies the prisoner at the bar, or person who takes his trial before the court of justiciary, for son

Pannel, in joinery, is a tympanum, or square piece of thin wood, sometimes carved, framed, or grooved in a larger piece, between two upright pieces and two cross pieces.

Pannel, in masonry, is one of the faces of a hewn stone.

PANTHER. See Felis.

PAPAVER, the *poppy*, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking under the 27th order, rhœadæ. The corolla is tetrapetalous; the calyx diphyllous; the capsule bilocular, opening at the pores below a persisting stigma. There are nine species: 1. The somniferum, or somniferous common garden-poppy. There are of this a great many varieties, some of them extremely beautiful. The white official poppy is one of the varieties of this sort. It grows often to the height of five or six feet, having large flowers, both single and double, succeeded by capsules or heads as large as oranges, each containing about 8000 seeds.

PAPER, sheets of a thin matter, made of some vegetable substance. The materials on which mankind have, in different ages, contrived to write their sentiments, have been extremely various; in the early ages they made use of stones and tables of [illegible], wax, ivory, &c. Paper, with regard to the manner of making it, and the materials employed therein, is reducible to several kinds; as Egyptian paper, made of the rush papyrus; bark paper made of the inner rind of several trees; cotton paper; incombustible paper; and European paper, made of linen rags.

Linen or European paper appears to have been first introduced among us towards the beginning of the fourteenth century, but by whom this valuable commodity was invented is not known. The method of making paper of linen or hempen rags is as follows:—the linen rags, being carried to the mill, are first sorted: instead of the old method of pounding the rag to

a pulp with large hammers, they now make use of an engine, which performs the work in much less time. This engine consists of a round solid piece of wood, into which are fastened long pieces of steel, ground very sharp. This is placed in a large trough with the rags, and a sufficient quantity of water. At the bottom of the trough is a plate with steel bars, ground sharp like the former; and the engine, being carried round with prodigious velocity, cuts and reduces the rags to a pulp in a very short time. It must be observed, that the motion of the engine causes the water in the trough to circulate, and by this means constantly returns the stuff to the engine. The trough is constantly fed with clear water at one end, while the dirty water from the rags is carried off at the other, through a hole defended with wire gratings, in order to hinder the pulp from going out with the dirty water. When the stuff is sufficiently prepared as above, it is carried to the vat, and mixed with a proper quantity of water, which they call *priming the vat.* The vat is rightly primed when the liquor has such a proportion of the pulp, as that the mould, on being dipped into it, will just take up enough to make a sheet of paper of the thickness required. The mould is a kind of sieve, exactly of the size of the paper to be made, and about an inch deep, the bottom being formed of fine brass wire, guarded underneath with sticks, to prevent its bagging down, and keep it horizontal; and further to strengthen the bottom, there are large wires, placed in parallel lines, at equal distances, which form those lines often visible in white paper when held up to the light: the mark of the paper is also made in this bottom, by interweaving a large wire in any particular form. This mould the maker dips into the liquor, and gives it a shake as he takes it out, to clear the water from the pulp. He then slides it along a groove to the coucher, who turns out the sheet upon a felt or woollen cloth laid upon a plank, lays another cloth on it, and returns the mould to the maker, who by this time has prepared a second sheet in another mould: and thus they proceed, laying alternately a sheet and a felt, till they have made six quires of paper, which is called a post; and this they do with such swiftness, that, in many sorts of paper, two men make twenty posts or more in a day. A post of paper being made, either the maker or coucher whistles; on which four or five men advance, one of whom draws it under the press, and the rest press it with great force, till all the water is squeezed from it; after which it is separated, sheet by sheet, from the felts, and laid regularly [illegible] sheet upon another; and having underg[illegible] a second pressing, it is hung up to dry. When sufficiently dried it is taken off the lines, rubbed smooth with the hands, and laid by till sized, which is the next operation. For this they choose a fine temperate day, and having boiled a proper quantity of clean parchment or vellum shavings, in water, till it comes to a size, they prepare a fine cloth, on which they strew a due proportion of white vitriol and roch-alum, finely powdered, and strain the size through it, into a large tub; in which they dip as much paper at once as they can conveniently hold, and with a quick motion give every sheet its share of the size, which must be as hot as the hand can well bear it. After this the paper is pressed, hung up sheet by sheet to dry; and, being taken down, is sorted, and what is only fit for outside quires, laid separately: it is then told into quires, which are folded and pressed. The broken sheets are commonly put together, and two of the worst quires are placed on the outside of every ream or bundle, and being tied up in wrappers, made of the settling of the vat, it is fit for sale

Paper is of various kinds, and used for various purposes: with regard to colour, it is principally distinguished into white, blue, and brown; and with regard to its dimensions, into atlas, elephant, imperial, super-royal, royal, medium, demy, crown, foolscap, and pot paper.

PAPIER MACHE, is a substance made of cuttings of white or brown paper, boiled in water, and beaten in a mortar till they are reduced into a kind of paste; and then boiled with a solution of gum arabic or of size, to give tenacity to the paste, which is afterwards formed into different toys, &c. by pressing it into oiled moulds. When dry, it is covered with a mixture of size and lamp-black, and afterwards varnished.

PAPILIO, *butterfly*, a genus of insects of the order lepidoptera. The generic character is, antennæ thickening towards the extremity, commonly terminating in a knob or elevated tip; wings (when sitting) erect, and meeting upwards: flight diurnal.

The prodigious number of species, amounting to many hundreds, in this genus, renders it absolutely necessary to divide the whole into sections or sets, instituted from the habit or general appearance, and, in some degree, from the distribution of colour on the wings. This division of the genus is conducted by Linnæus in a peculiarly elegant and instructive manner, being an attempt to combine, in some degree, natural and civil history, by attaching the memory of some illustrious ancient name to an insect of a certain particular cast.

PAPISTS, persons professing the popish religion. By several statutes, if any English priest of the church of Rome, born in the dominions of the crown of England, came to England from beyond the seas, or tarried in England three days without conforming to the church, he was guilty of high treason; and they also incurred the guilt of high treason who were reconciled to the see of Rome, or procured others to be reconciled to it. By these laws also, papists were disabled from giving their children any education in their own religion. If they educated their children at home, for maintaining the schoolmaster, if he did not repair to church, or was not allowed by the bishop of the diocese, they were liable to forfeit £10 a month, and the schoolmaster was liable to the forfeiture of 40s. a day; if they sent their children for education abroad, they were liable to forfeit £100, and the children so sent were incapable of inheriting, purchasing, or enjoying any lands, profits, goods, debts, legacies, or sums of money: saying mass was punishable by a forfeiture of 200 marks; and hearing it by a forfeiture of £100. But, during the late reign, the Roman Catholics have been in some measure relieved from many of the odious and unjust restrictions formerly imposed

on them. See 18 Geo. III. c. 60: and 31 Geo. III. c. 22.

Yet as the statute 1 William and Mary, st. 1, c. 18, called the Toleration Act, does not apply to Catholics, nor to persons denying the Trinity, they cannot serve in corporations, and are liable to the Test and Corporation Act. They cannot sit in the House of Commons, nor vote at elections, without taking the oath of supremacy, and cannot present to advowsons, although Jews and Quakers may. But the person is only disabled from presenting, and still continues patron. It seems they may serve on juries, but Catholic ministers are exempted. They also are entitled to attend the British factories and their meetings abroad, and may hold offices to be wholly exercised abroad, and may also serve under the East India Company, or in the army abroad, and the 60th regiment is chiefly composed of persons who cannot serve in England, by reason of the officers.

PAPOPHORUM, a genus of the class and order triandria digynia. The calyx is two-valved, two-flowered; corolla two-valved, many-awned. There is one species, a grass of America.

PAPUS, *down* See *Botany*.

PAR, in commerce. See *Exchange*.

PARABOLA, in geometry, a figure arising from the section of a cone, when cut by a plane parallel to one of its sides. See *Conic Sections*.

PARABOLIC CONOID, in geometry, a solid generated by the rotation of a parabola about its axis: its solidity is $= \frac{1}{2}$ of that of its circumscribing cylinder. The circles conceived to be the elements of this figure, are in arithmetical proportion, decreasing towards the vertex.

A parabolic conoid is to a cylinder of the same base and height as 1 to 3; and to a cone of the same base and height as 1½ to 1. See *Gauging*.

PARABOLIC *Space*, the area contained between any entire ordinate and the curve of the incumbent parabola.

The parabolic space is to the rectangle of the semi-ordinate into the abscis, as 2 to 3; to a triangle inscribed on the ordinate as a base, it is as 4 to 3.

PARABOLOIDES, a name given to parabolas of the higher kind, which are algebraic curves.

PARACENTRIC MOTION, in astronomy, denotes so much as a revolving planet approaches nearer to, or recedes from, the sun, or centre of attraction.

PARADE, in war, is a place where the troops meet to go upon guard, or any other service. In a garrison where there are two, three, or more regiments, each have their parade appointed, where they are to meet upon all occasions, especially upon any alarm. And in a camp, all parties, convoys, and detachments have a parading place appointed them at the head of some regiment.

PARADISEA, *the bird of Paradise*, in natural history, a genus of birds of the order Picæ. Generic character, bill covered at the base with downy feathers; nostrils covered by the feathers; tail of ten feathers, two of them in some species, very long; legs and feet very large and strong. These birds chiefly inhabit North Guinea, from which they migrate in the dry season into the neighbouring islands. They are used in these countries as ornaments for the head-dress, and the Japanese, Chinese, and Persians, import them for the same purpose. —The rich and great among the latter attach these brilliant collections of plumage not only to their own turbans, but to the housings and harnesses of their horses. They are found only within a few degrees of the equator. Gmelin enumerates twelve species, and Latham eight. P. apoda, or the greater Paradise bird is about as large as a thrush.

These birds are supposed to breed in North Guinea whence they migrate into Aroo, returning to North Guinea with the wet monsoon. They pass in flights of thirty or forty, headed by one whose flight is higher than that of the rest. They are often distressed by means of their long feathers in sudden shiftings of the wind, and unable to proceed in their flight, are easily taken by the natives, who also catch them with birdlime, and shoot them with blunted arrows. They are sold at Aroo for an iron nail each, and at Banda for half a rix dollar. Their food is not ascertained, and they cannot be kept alive in confinement. The smaller bird of Paradise is supposed by Latham to be a mere variety of the above. It is found only in the Papuan islands, where it is caught by the natives often by the hand, and exenterated and seared with a hot iron in the inside, and then put into the hollow of a bamboo to secure its plumage from injury.

PARADOX, in philosophy a proposition seemingly absurd, as being contrary to some received opinion; but yet true in fact.

PARAGOGE, in grammar, a figure whereby a letter or syllable is added to the end of a word; as *med*, for *me*; *dicier*, for *dici*, &c.

PARALACTIC, in general, something relating to the parallax of heavenly bodies. See *Parallax*.

PARALLAX, in astronomy, denotes a change of the apparent place of any heavenly body, caused by being seen from different points of view; or it is the difference between the true and apparent distance of any heavenly body from the zenith.

PARALLAX, *annual*, the change of the apparent place of a heavenly body, which is caused by being viewed from the earth in different parts of its orbit round the sun.

PARALLEL, in geometry, an appellation given to lines, surfaces, and bodies, every where equidistant from each other; and which, though infinitely produced, would never meet.

PARALLEL RULER, an instrument, consisting of two wooden, brass, &c. rul[illegible], equally broad everywhere; and so joined together by cross blades as to open to different intervals, accede and recede, and yet still retain their parallelism.

PARALLELS *of latitude*, in astronomy, are lesser circles of the sphere parallel to the ecliptic, imagined to pass through every degree and minute of the colures.

PARALLELS *of altitude*, or Almucantars, are circles parallel to the horizon, imagined to pass through every degree and minute of the meridian between the horizon and zenith, having their poles in the zenith. They are represented on the globe by the divisions on the quadrant of altitude, in its motion about the body of the globe, when screwed to the zenith.

Parallels *of declination*, in astronomy, are the same with parallels of latitude in geography.

Parallel sphere, that situation of the sphere, wherein the equator coincides with the horizon, and the poles with the zenith and nadir. In this sphere all the parallels of the equator become parallels of the horizon, consequently no stars ever rise or set, but all turn round in circles parallel to the horizon; and the sun, when in the equinoctial, wheels round the horizon the whole day. After his rising to the elevated pole, he never sets for six months; and after his entering again on the other side of the line, never rises for six months longer.

This is the position of the sphere to such as live under the poles, and to whom the sun is never higher than 23° 30′.

Parallel sailing, in navigation, is the sailing under a parallel of latitude. See Navigation.

PARALLELEPIPED, or **Parallelopiped**, in geometry, a regular solid comprehended under six parallelograms, the opposite ones whereof are similar, parallel, and equal. See Geometry.

PARALLELOGRAM. See *Geometry*.

PARALLOGISM, in logic, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false; or, though true, are not proved; or when a proposition is passed over that should have been proved by the way.

PARALYSIS the palsy. See *Medicine*.

PARAMETER, in conic sections, a constant line, otherwise called latus rectum. See Conic Sections.

PARAPET, in fortification, an elevation of earth designed for covering the soldiers from the enemy's cannon or small shot. The thickness of the parapet is from 18 to 20 feet; its height is six feet on the inside, and four or five on the outside.

PARAPHRASE, an explanation of some text, in clearer and more ample terms, whereby is supplied what the author might have said or thought on the subject; such are esteemed Erasmus's Paraphrase on the New Testament, the Chaldee Paraphrase on the Pentateuch, &c.

PARASANG, an ancient Persian measure, different at different times, and in different places; being sometimes 30, sometimes 40, and sometimes 50 stadia or furlongs.

PARASITES, or **Parasitical Plants**, in botany, such plants as are produced out of the trunk or branches of other plants, from whence they receive their nourishment, and will not grow upon the ground, as the misleto, &c.

PARCEL-MAKERS, two officers in the exchequer, who make parcels of the escheator's accounts, in which they charge them with every thing they have levied for the king's use, within the time of their office, and deliver the same to one of the auditors of the court, to make their accounts therewith.

PARCHMENT, in commerce, the skin of sheep or goats prepared after such a manner as to render it proper for writing upon, covering books, &c.

PARDON, is the remitting or forgiving a felony or other offence committed against the king. Blackstone mentions the power of pardoning offences to be one of the greatest advantages of monarchy, in general, above every other form of government, and which cannot subsist in democracies. Its utility and necessity are defended by him on all those principles which do honour to human nature.

Pardons are either general or special: general, as by act of Parliament, of which, if they are without exceptions, the court must take notice, *ex officio;* but if there are exceptions therein, the party must aver, that he is none of the persons excepted: special pardons, are either of course, as to persons convicted of manslaughter, or *se defendendo*, and by several statutes, to those who shall discover their accomplices in several felonies; or of grace, which are by the king's charter, of which the court cannot take notice, *ex officio*, but they must be pleaded. A pardon may be conditional, that is, the king may extend his mercy upon what terms he pleases; and may annex to his bounty a condition, either precedent or subsequent, on the performance whereof, the validity of the pardon will depend; and this by the common law.

All pardons must be under the great seal. The effect of a pardon is to make the offender a new man; to acquit him of all corporal penalties and forfeitures annexed to that offence, and to give him a new credit and capacity; but nothing but an act of Parliament can restore or purify the blood after an attainder.

PAREGORICS, medicines that assuage pain, otherwise called anodynes.

PARENTHESIS, in grammar, certain intercalary words, inserted in a discourse; which interrupt the sense or thread, but seem necessary for the better understanding of the subject.

PARENTS AND CHILDREN. If parents run away, and leave their children at the charge of the parish, the churchwardens and overseers, by order of the justices, may seize the rents, goods, and chattels, of such parents, and dispose thereof towards their children's maintenance.

A parent may lawfully correct his child, being under age, in a reasonable manner; but the legal power of the father over the persons of his children, ceases at the age of 21. 1 Black. 452.

PARHELION. See Optics.

PARISH. In England there are 9913 parishes, of which 3845 are churches impropriate, and the rest are annexed to colleges or church dignities. In many of these parishes, on account of their large extent and the number of parishioners, there are several chapels of ease.

Parish *clerk*. In every parish the parson, vicar, &c. hath a parish clerk under him, who is the lowest officer of the church. These were formerly clerks in orders, and their business at first was to officiate at the altar, for which they had a competent maintenance by offerings; but now they are laymen, and have certain fees with the parson on christenings, marriages, burials, &c. besides wages for their maintenance.

PARLIAMENT. The parliament is the legislative branch of the supreme power of Great Britain, consisting of the King, the Lords spiritual and temporal, and the Knights, Citizens, and Burgesses, representatives of the Commons of the Realm, in Parliament assembled.

The power and jurisdiction of Parliament is so transcendant and absolute that it cannot be confined, either for causes or persons, within any bounds.

The Parliament must be summoned by the King, and not by authority of either house, at least forty days before it sits, although the Convention Parliament (the House of Commons), from necessity, was summoned by the Keepers of the Liberty of England, by authority of Parliament. It cannot begin without the King in person, or by representation.

The house of Commons is a denomination given to the lower house of parliament. In a free state, every man, who is supposed a free agent, ought to be, in some measure, his own governor; and therefore a branch at least of the legislative power should reside in the whole body of the people. In elections for representatives for Great Britain, anciently, all the people had votes; but king Henry VI. to avoid tumults, first appointed that none should vote for knights but such as were freeholders, did reside in the county, and had forty shillings yearly revenue. In so large a state as ours, therefore, it is very wisely contrived, that the people should do that by their representatives which it is impracticable to perform in person; representatives chosen by a number of minute and separate districts, wherein all the voters are or may be easily distinguished. The counties are therefore represented by knights, elected by the proprietors of lands; the cities and boroughs are represented by citizens and burgesses, chosen by the mercantile or supposed trading interest of the nation.

The number of members returned to Parliament from England, Scotland, and Ireland, is 658.

The peculiar laws and customs of the House of Commons, relate principally to the raising of taxes, and the election of members to serve in Parliament.

The method of making laws is nearly the same in both houses. In the House of Commons, in order to bring in the bill, if the relief sought is of a private nature, it is first necessary to prefer a petition; which must be presented by a member, and usually set forth a grievance required to be remedied. This petition, when founded on facts of a disputable nature, is referred to a committee of members, who examine the matter alleged, and accordingly report it to the house; and then (or otherwise upon the mere petition), leave is given to bring in the bill. In public matters, the bill is brought in upon motion made to the house, without any petition.

If the bill begins in the House of Lords, if of a private nature, it is referred to two judges, to make report. After the second reading, the bill is said to be committed, that is, referred to a committee; which is selected by the house, in matters of small importance; or upon a bill of consequence, the house resolves itself into a committee of the whole house. A committee of the whole house is composed of every member; and to form it the speaker quits the chair, and may consequently sit and debate upon the merits of it as a private member, another member being appointed chairman for the time. In these committees the bill is usually debated clause by clause, amendments made, and sometimes it is entirely new-modelled. Upon the third reading, further amendments are sometimes made; and if a new clause is added, it is done by tacking a separate piece of parchment on the bill, which is called a rider.

The royal assent must be given to the bill before it can pass into a law; and this is done by letters patent under the king's seal, and signed with his own hand.

An act of parliament thus made is the exercise of the highest authority that this kingdom acknowledges upon the earth.

Adjournment is no more than a continuance of the session from one day to another, as the word itself signifies; and this is done by the authority of each house separately every day, or for a longer period; but the adjournment of one house is no adjournment of the other. 1 Black. 186.

Prorogation is the continuance of the parliament from one session to another, as an adjournment is a continuation of the session from day to day. And this is done by the royal authority, expressed either by the lord chancellor in his majesty's presence, or by commission from the crown, or frequently by proclamation; and by this, both houses are prorogued at the same time, it not being a prorogation of the house of lords or commons, but of the parliament. The session is never understood to be at an end until a prorogation; though, unless some act is passed, or some judgment given in parliament, it is in truth no session at all. Id.

A dissolution is the civil death of the parliament; and this may be effected three ways: 1. By the king's will expressed either in person or representation; 2. By the demise of the crown; 3. By the length of time.

By the king's will; for, as the king has the sole right of convening the parliament, so also it is a branch of the royal prerogative, that he may whenever he pleases, prorogue the parliament for a time, or put a final period to its existence.

By the demise of the crown: this dissolution formerly happened immediately upon the death of the reigning sovereign; but the calling a new parliament immediately on the inauguration of the successor being found inconvenient, and dangers being apprehended from having no parliament in being, in case of a disputed succession, it was enacted by statutes 7 and 8 W. III. c. 15, and 6 Anne, c. 7, that the parliament in being shall continue for six months after the death of any king or queen, unless sooner prorogued or dissolved by the successor; that if the parliament is at the time of the king's death separated by adjournment or prorogation, it shall notwithstanding assemble immediately; and that if no parliament is then in being, the members of the last parliament shall assemble and be again a parliament.

Lastly, a parliament may be dissolved or expire by length of time.

The utmost extent of time that the same parliament was allowed to sit by the stat. of 6 W. c. 3. was three years; after the expiration of which, reckoning from the return of the first summons, the parliament was to have no longer continuance. But by stat. 1. Geo. I. c. 38. in order professedly to prevent the great and continued expences of frequent elections, and the violent heats and animosities consequent

thereupon, and for the peace and security of the government just then recovering from the late rebellion, this term was prolonged to seven years. So that as our constitution now stands, the parliament must expire, or die a natural death, at the end of every seventh year, if not sooner dissolved by the royal prerogative. See Election.

Parliament, *the high court of*, is the supreme court of the kingdom, not only for the making but also for the execution of laws, by the trial of great and enormous offenders, whether lords or commoners, in the method of parliamentary impeachment. An impeachment before the lords, by the commons of Great Britain in parliament, is a prosecution of the already known and established law, and has been frequently put in practice; being a presentment to the most high and supreme court of criminal jurisdiction by the most solemn grand inquest of the whole kingdom. A commoner cannot, however, be impeached before the lords for any capital offence, but only for high misdemeanors; a peer may be impeached for any crime. And they usually, in case of an impeachment of a peer for treason, address the crown to appoint a lord high steward, for the greater dignity and regularity of their proceedings: which high steward was formerly elected by the peers themselves, though he was generally commissioned by the king; but it has of late years been strenuously maintained, that the appointment of a high steward in such cases is not indispensably necessary, but the house may proceed without one. The articles of impeachment are a kind of bills of indictment, found by the house of commons, and afterwards tried by the lords; who are in cases of misdemeanors considered not only as their own peers, but as the peers of the whole nation.

PARODY, a popular maxim, adage, or proverb. Parody is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule to another; or in turning a serious work into a burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, and cadences.

PAROLE, a term signifying any thing done verbally or by word of mouth in contradistinction to what is written: thus, an agreement may be by parole. Evidence also may be divided into parole evidence and written evidence. A parole release is good to discharge a debt by simple contract.

PARROT, and **PARROQUET**. See Psittachus.

PARSLEY. See Apium.

PARSNEP. See Pastinaca.

PARSON, signifies the incumbent of a church. He is in himself a body corporate, in order to protect and defend the rights of the church by a perpetual succession. When a parson is instituted and inducted into a rectory, he is then, and not before, in full and complete possession. 1 Black. 391.

PART, in music, the name of each of the melodies of any harmonic composition, and which, when performed in union, form its harmony. Four is the fewest number of parts with which the chords necessary to elaborate harmony can be completely filled.

PARTERRE, in gardening, a level division of ground, which, for the most part, faces the south, and best front of a house; and is generally furnished with greens, flowers, &c.

PARTICIPLE. See Grammar.

PARTICLE, in grammar, a denomination for all those small words that tie or unite others together, or that express the modes or manners of words.

PARTIES, in law, signify the persons that are named in a deed or fine, viz. those that made the deed, or levied the fine, and also those to whom the same was made or levied.

PARTITION, in law, signifies a division of lands, &c. descended by common law or custom among coheirs or parceners, being two at least.

PARTNER. If there are several joint partners, and a person has dealings generally with one of them in matters concerning their joint trade, whereby a debt becomes due to the said person, it shall charge them jointly and the survivors of them; but if the person only dealt with one of the partners upon a separate account, in that case the debt shall only affect that partner and his executors. If one or more of the joint traders become bankrupt, his or their proportions are only assignable by the commissioners, to be held in common with the rest who are not bankrupts. If one or two partners becomes a bankrupt, the commissioners cannot meddle with the interest of the other, for it is not affected with the bankruptcy of his companion. Payment to one of the partners is payment to them all.

PART-OWNERS, are partners interested and possessed of certain shares in a ship. Owners are tenants in common with each other; but one or more joint-owners refusing to contribute their quota to the outfit of the vessel, cannot prevent her from going to sea against the consent of the majority of the owners, who, giving security in the Admiralty, may freight the ship at their own exclusive risk, by which the smaller dissentient number of owners will be excluded at once from any share, either in the risk or in the profits.

PARTRIDGE. See Tetrao.

PARUS, or Titmouse, in ornithology, a genus belonging to the order of passeres. The bill is very entire, covered at the basis with hairs; the tongue is truncated and hairy. There are 14 species.

PASQUIN, a mutilated statue at Rome, in a corner of the palace of the Ursini: it takes its name from a cobler of that city called Pasquin, famous for his sneers and gibes, and who diverted himself with passing his jokes on all the people who went through that street.

PASS, a straight, difficult, and narrow passage, which shuts up the entrance into a country. The first care of the general of an army is to seize the passes of the country into which he would carry the war, to fortify them, and take care that they are well guarded.

PASSAGE, or Passo, any phrase or short portion of any air, or other composition.

Passage, *birds of*. See Migration.

PASSANT. See Heraldry.

PASSERES, in natural history, the sixth order of birds according to the Linnæan system, they are distinguished by a conical and pointed bill; nostrils oval, pervious, naked; legs formed for hopping; toes slender, divided,

body slender, flesh of such as feed on grain pure; of those which feed on insects impure; nest formed with much art. They live chiefly in trees and hedges, are monogamous, vocal, and feed the young by thrusting the food down their throats.

PASSIONS, in painting: the passions are properly considered as subjects of painting, because being capable of representation by lines and colours, they fall within the province of that art, whose office it is to delineate all objects which can be expressed by those means. To represent the passions justly and fully, is, however, the utmost reach of the imitative art. The nicest accuracy is requisite, and the smallest deviation is frequently destructive of the whole effect intended to be produced.

Le Brun, a celebrated French painter, published a collection of heads, in which he gave examples of the appearances produced in the countenance by each distinct passion But these examples are for the most part overcharged and gross.

PASSPORT, or PASS, a licence or writing obtained from a prince or governor, granting liberty and safe conduct to pass through his territories without molestation. Passport also signifies a licence obtained for importing contraband goods, or for exporting and importing merchandize without paying the duties; these last licences are always given to ambassadors and other public ministers for their baggage, equipage, &c.

PASTE, in the glass trade, a kind of coloured glass, made of calcined crystal, lead, and metallic preparations, so as to imitate the natural gems: for the manner of effecting which see GEMS.

PASTEBOARD, a kind of thick paper formed of several sheets of paper pasted together. The chief use of pasteboard is in binding books, making letter-cases, &c.

PASTINACA, the *parsnip*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is an elliptical compressed plane; the petals are involuted and entire. There are only three species of this genus, the principal of which is the pastinaca sativa, or garden parsnip, which is an exceedingly fine esculent root.

PASTORAL, in general, something that relates to shepherds; hence we say, pastoral life, manners, poetry, &c. The original of poetry is ascribed to that age which succeeded the creation of the world; and as the keeping of flocks seems to have been the first employment of mankind, the most ancient sort of poetry was probably pastoral.

PATENT, something that stands open or expanded: thus a leaf is said to be patent when it stands nearly at right angles with the stalk.

PATENT, or *Letters Patent*, are writings sealed with the great seal of England, by which a man is authorized to do, or to enjoy, any thing which of himself he could not. They are so called on account of their form, being open, with their seal affixed, ready to be exhibited for the confirmation of the authority delegated by them.

PATHOLOGY, that part of medicine which explains the symptoms of diseases.

PATROL, in war, a round or march made by the guards, or watch, in the night-time, to observe what passes in the streets, and to secure the peace and tranquillity of a city or camp. The patrol generally consists of a body of five or six men, detached from a body or guard, and commanded by a serjeant.

PATRON, both in the canon and common law, signifies him that hath the gift of a benefice or parsonage.

PATRONYMIC, among grammarians, is applied to such names of men and women as are derived from those of parents or ancestors.

PAUPER, *poor*, a name applied to a person receiving public charity.

PAVEMENT, a layer of stone, or other matter, serving to cover and strengthen the ground of divers places for the more commodious walking on. In London the pavement for coach-ways is chiefly a kind of granite from Scotland: and on the footpath Yorkshire paving is used; courts, stables, kitchens, halls, churches, &c. are paved usually with tiles, bricks, or fire-stones; and sometimes with a kind of free-stone and rag-stone. In France, the public roads, streets, courts, &c. are paved with gres, a kind of free stone. In Venice, the streets, &c. are paved with brick; churches sometimes with marble, and sometimes with Mosaic work. In Amsterdam, and the chief cities of Holland, they call their brick pavement the burgomaster's pavement, to distinguish it from the stone or flint pavement, which is usually in the middle of the street, serving for the passage of their horses, carts, coaches, and other carriages; the brick borders being designed for the passage of people on foot.

PAVO, the *peacock*, in ornithology, a genus belonging to the order of gallinæ. The head is covered with feathers which bend backwards; the feathers of the tail are very long, and beautifully variegated with eyes of different colours. Latham enumerates eight species. In this country, peacocks do not attain their full and brilliant plumage till their third year. The female lays five eggs, and is particularly solicitous to conceal them from the male, which not unfrequently destroys them. These birds feed almost solely on insects and grain. They prefer elevated situations for roosting, choosing the tops of houses and the highest trees for this purpose. They were considered as luxuries for the table by the Romans, and the young ones are now regarded as a delicacy. Their voice is harsh and dissonant, and in perfect contrast to that beauty exhibited by their plumage, which, in the language of Buffon, "seems to combine all that delights the eye in the soft and delicate tints of the finest flowers, all that dazzles in the sparkling lustre of the gem, and all that astonishes in the grand display of the rainbow."

PAUSE, a stop or cessation of speaking, singing, playing, or the like. The use of pointing, in grammar, is to make proper pauses in certain places. There is a pause in the middle of each verse; in an hemistich it is called a rest or repose.

PAUSUS, a genus of insects, of the order coleoptera. The generic character is: antennæ of two joints, the upper very large, inflated, moveable, and hooked; head stretched forwards; wing-sheaths flexile, deflected, truncated.

This rare insect is a native of Banana Island, and Sierra Leone in Africa. Its colour is a blackish brown.

PAWLE, in a ship, a small piece of iron bolted to one end of the beams of the deck, close to the capstan; but yet so easily, as that it can turn about. Its use is to stop the capstan from turning back.

PAWN, a pledge lodged for the security of the payment of a sum of money borrowed. As the party that pawns the goods has a general property therein, they cannot be forfeited by the person that has them in pawn, for any offence of his; neither can they be taken in execution for his debt. Where the pawn is redeemable on a certain day, it must be strictly observed, or upon failure of payment it may be sold.

PAY, in the sea language. The seamen say, pay more cable, when they mean to let out more cable.

PAYING, among seamen. When the seams of a ship are laid over with a coat of hot pitch, it is called paying her; and when this is done with canvas, parcelling; also when, after she is graved, and the soil burned off, a new coat of tallow and soap, or one of train oil, rosin, and brimstone boiled together, is put on her, that is also called paying of a ship.

PAYMENT, is the consideration or purchase-money for goods, and may be made by the buyer giving to the seller the price agreed upon, either by bill or note, or by money.

PEACE, in law, signifies a quiet and harmless behaviour towards the king and his people. The king, by his office and dignity royal, is the principal conservator of the peace within all his dominions, and may give authority to any other to see the peace kept, and to punish such as break it: hence it is usually called the king's peace.

PEACE, *justices of the*, are persons appointed by the king's commission to attend to the peace of the county where they dwell. They were called guardians of the peace till the 36th year of Edw. III. c. 12, where they are called justices.

A justice of the peace must, before he sits, take the oath of office, which is always done at the general quarter sessions for the county, by virtue of a dedimus potestatem out of chancery.

Sheriffs, coroners, attorneys, and proctors, may not act as justices of the peace.

The power, office, and duty of this magistrate, extends to an almost infinite number of instances, specified in some hundreds of acts of parliament, and every year accumulating.

PEACH, in botany. See Amygdalus.

PEACOCK. See Pavo.

PEARL. The pearl is a concretion found in several species of shells, as in some species of the oyster and the muscle. Pearls are of a silvery or blueish white colour, and very brilliant. They are formed of the same matter as the inner shell of the fish to which they belong, and consist of several coats spread with the greatest regularity over each other in a manner similar to those of an onion. The most important fishery to England at present is that of Ceylon. There are various methods of fishing for pearls in different parts of the world, but the Ceylon fishery is reckoned superior to them all.

Pearl, *mother of*, is the shell not of the pearl oyster, but of another sea-fish of the oyster kind. This shell on the inside is extremely smooth, and of the whiteness and water of pearl itself; and it has the same lustre on the outside, after the first laminæ or scales have been cleared off.

Pearls, *artificial*. As the genuine pearls are sold at an extravagant price, various methods have been contrived of imitating them so completely, that they can scarcely be distinguished from those collected in the East. The principal ingredient employed for this purpose consists of the fine silvery matter which is found on the lower side of the scales of the blay, or bleak fish *(Cyprinus alburnus)*. These scales are first removed; then washed repeatedly in pure water; and, after the different liquors have subsided, the fluid part is carefully decanted; when a pearly matter, of an oily consistence, remains at the bottom; which is denominated by the French, *Essence d'Orient*. A small portion of this matter is dropped in a hollow, bluish glass-bead, that is gently agitated, till the whole internal surface is completely lined; when the cavity is filled up with wax, in order to impart solidity and weight. Pearls thus manufactured, possess fewer blemishes than such as are natural or genuine, to which they are fully equal in point of brilliancy.

PEAT, a well-known inflammable substance, used in many parts of the world as fuel.

Peat is a congeries of vegetable matter, in which the remains of organization are more or less visible; consisting of the trunks of trees; of leaves, fruits, and stringy fibres, the remains of aquatic mosses. It occurs in extensive beds called peat mosses, occupying the surface of the soil, or covered to the depth of a few feet with sand, gravel, and other matters. It is met with in great abundance in the northern, and in some of the central districts of Europe: in moist, uncultivated, mountainous tracts, and likewise in low vallies and fenny plains; and in several parts of the western shore of Great Britain.

PEBBLES, the name of a genus of fossils, distinguished from the flints by having a variety of colours. These are defined to be stones composed of a crystalline matter debased by earths of various kinds in the same species: and then subject to veins, clouds, and other variegations, usually formed by incrustation round a central nucleus, but sometimes the effect of a simple concretion; and veined like the agates, by the disposition which the motion of the fluid they were formed in gave their differently-coloured substances.

PECK, a measure of capacity, four of which make a bushel.

PECORA, in natural history, the fifth order of the class mammalia. They have no foreteeth in the upper jaw, but several in the lower; feet hoofed, cloven: they live on herbs, chew the cud, and have four stomachs: viz. the paunch, to macerate and ruminate the food; the bonnet, reticulate, to receive it; the omasus, of numerous folds, to digest it; and the abomasus, to give it acescency, and prevent putrefaction. There are eight genera, viz.

Antelope
Bos
Camelus
Camelopardalis
Capra
Cervus
Moschus
Ovis.

PECTEN, the *scallop;* a genus of shell-fish, the characters of which are these: the animal is a tethys; the shell bivalve and unequal; the hinge toothless, having a small ovated hollow.

PEDESTAL. See ARCHITECTURE.

PEDICELLARIA, a genus of insects, of the order vermes mollusca: the generic character is, body soft and seated on a rigid peduncle; aperture single. There are three species.

PEDICULARIS, *red-rattle, or louse-wort*, a genus of the didynamia angiospermia glass of plants, the corolla whereof consists of a single ringent petal; the tube is oblong and gibbous: the upper lip galeated, erect, compressed, and emarginated; the under one is patent, plane, semitrifid, and obtuse; the fruit is a roundish acuminated capsule; the seeds are numerous, roundish, compressed, and covered. There are 19 species.

PEDICULUS, louse, a genus of insects of the order aptera: the generic character is, legs six, formed for walking; mouth furnished with an exsertile piercer; antennæ the length of the thorax; abdomen depressed, sublobated. Few insects are more prolific than the louse. It is said, that in about eight weeks a louse might see five thousand of its own descendants.

PEDIMENT, in architecture, is a kind of low pinnacle, serving to crown an ordonnance, or finish a frontispiece, and is placed as an ornament over gates, doors, windows, niches, altars, &c. being ordinarily of a triangular form, but sometimes forming an arch of a circle.

PEDOMETER. See PERAMBULATOR.

PEEK, in the sea language, is a word used in various senses. Thus the anchor is said to be a peek, when the ship being about to weigh, comes over her anchor in such a manner that the cable hangs perpendicularly between the hawse and the anchor. To heave a peek, is to bring the peek so that the anchor may hang a peek. A ship is said to ride a peek. when lying with her main and fore-yards hoisted up, one end of her yards is brought down to the shrouds, and the other raised up on end; which is chiefly done when she lies in rivers, lest other ships falling foul of the yards should break them.

PEER, in general, signifies an equal, or one of the same rank and station: hence, in the acts of some councils, we find these words, with the consent of our peers, bishops, abbots, &c. Afterwards the same term was applied to the vassals or tenants of the same lord, who were called peers, because they were all equal in condition, and obliged to serve and attend him in his courts: and peers in *fief*, because they all held fiefs from the same lord.

The term peers is now applied in our common law to those who are impannelled in an inquest upon any man, for the convicting or clearing him of any offence, for which he is called in question; and the reason is, because the course and custom of our nation is, to try every man in such a case by his equals, or peers.

PEERS *of the realm*, are the nobility of the kingdom, and lords of parliament; who are divided into dukes, marquises, earls, viscounts, and barons and the reason why they are called peers is, because, notwithstanding there is a distinction of dignities in our nobility, yet in all public actions they are equal, as in their votes of parliament, and in passing upon the trial of any nobleman.

PEERESS, a woman who is noble by descent, creation, or marriage. If a peeress, by descent or creation, marries a person under the degree of nobility, she still continues noble; but if she obtains that dignity only by marriage, she loses it on her afterwards marrying a commoner; yet, by the courtesy of England, she always retains the title of her nobility.

PEGASUS, in astronomy, a northern constellation, containing, according to the latest observations, about fifty-six stars.

PEGASUS is also a genus of fishes of the order nantes: the generic character is, snout elongated. mouth beneath; pectoral fins large, ventral single-rayed; body depressed, mailed, with the abdomen divided into bony segments

PELAGIANS, a Christian sect who appeared before the latter part of the fourth, or the beginning of the fifth century. Pelagius, the author of this sect, was born in Wales, and his name was Morgan, which in the Welsh language signifies sea-born; whence he had his Latin name Pelagius. He was charged with maintaining the following doctrines: 1. That Adam was by nature mortal, and whether he had sinned or not, would certainly have died 2. That the consequences of Adam's sin were confined to his own person. 3. That new-born infants are in the same condition with Adam before the fall. 4. That the law qualified men for the kingdom of heaven, and was founded upon equal promises with the gospel. 5. That the general resurrection of the dead does not follow in virtue of our Saviour's resurrection. 6. That the grace of God is given according to our merits. 7. That this grace is not granted for the performance of every moral act; the liberty of the will, and information in points of duty, being sufficient. &c.

PELICANUS, in ornithology, a genus belonging to the order of anseres. The bill is straight, without teeth, and crooked at the point; the face is naked; and the feet are palmated. Mr. Latham enumerates no less than 30 different species of this genus, beside varieties. The most remarkable seem to be these that follow.

P. onocrotalus, or the great pelican, is sometimes of the weight of twenty-five pounds, and of the width, between the extreme points of the wings, of fifteen feet; the skin, between the sides of the upper mandible, is extremely dilatable. reaching more than half a foot down the neck, and capable of containing many quarts of water. This skin is often used by sailors for tobacco-pouches, and has been occasionally converted into elegant ladies' work-bags. About the Caspian and Black Seas, these birds are very numerous, and they are chiefly to be found in the warmer regions, inhabiting almost every country of Africa.

P. aquilus, or the man-of-war bird, is small in body, but between the extremities of the wings fourteen feet in width. It is seldom seen but within the tropics, and not unfrequently is observed 200 leagues from land. It watches the movements of fishes from a very considerable height, and pounces upon them with unfailing success, returning from its immersion with

equal rapidity. It also often obliges other birds to quit the prey which they have just made, and are flying off with, and seizes it as it drops from them with a dexterity truly admirable.

1. The *carbo,* or cormorant, sometimes exceeds seven pounds in weight; the length three feet four; the extent four feet two; the bill dusky, five inches long, destitute of nostrils; the base of the lower mandible is covered with a naked yellow skin, that extends under the chin, and forms a sort of pouch; a loose skin of the same colour reaches from the upper mandible round the eyes and angles of the mouth; the head and neck are of a sooty blackness, but under the chin of the male the feathers are white; and the head in that sex is adorned with a short, loose, pendant crest; in some the crest and hind part of the head are streaked with white.

The birds occupy the highest parts of the cliffs that impend over the sea: they make their nest of sticks, sea-tang, grass, &c. and lay six or seven white eggs of an oblong form. In winter they disperse along the shores, and visit the fresh waters, where they make great havoc among the fish. The cormorant has the rankest and most disagreeable smell of any bird, even when alive. Its form is disagreeable, its voice hoarse and croaking, and its qualities base. These birds, however, have been trained to fish, as falcons to fowl. Whitelock tells us, that he had a cast of them manned like hawks, and which would come to hand. He took much pleasure in them; and relates, that the best he had was one presented him by Mr. Wood, master of the cormorants to Charles I.

The *bassanus,* gannet, or solan goose, weighs seven pounds; the length is three feet one inch; the breadth six feet two inches. The bill is six inches long, straight almost to the point where it inclines down; and the sides are irregularly jagged, that it may hold its prey with more security; it has no nostrils, but in their place a long furrow, that reaches almost to the end of the bill; the whole is of a dirty white, tinged with ash-colour. These birds frequent the isle of Alisa, in the frith of Clyde; the rocks adjacent to St. Kilda; the Stalks of Souliskerry, near the Orkneys; the Skelig Isles off the coasts of Kerry, Ireland; and the Bass Isle in the frith of Forth; the multitudes that inhabit these islands are prodigious.

PELLICLE, among physicians, &c. denotes a thin film, or fragment of a membrane.

PELVIS, in anatomy, the lower part of the cavity of the abdomen; thus called from its resemblance to a bason, in Latin called pelvis

PEN, *fountain,* is a pen made of silver, brass, &c. contrived to contain a considerable quantity of ink, and let it flow out by gentle degrees, so as to supply the writer a long time without being under the necessity of taking fresh ink.

PENALTY, is a forfeiture inflicted for not complying with the regulations of certain acts of parliament; a penalty is also annexed to secure the performance of certain covenants in a deed, articles of agreement, copartnership, &c. In a bond also for payment of money, it is usual to annex a penalty in double the amount of the obligation.

PENCIL, an instrument used by painters for laying on their colours. Pencils are of various kinds, and made of various materials, the larger sorts are made of boars' bristles, the thick ends of which are bound to a stick, bigger or less according to the uses they are designed for; these, when large, are called brushes. The finer sorts of pencils are made of camels, badgers, and squirrels' hair, and of the down of swans; these are tied at the upper end with a piece of strong thread, and inclosed in the barrel of a quill. All good pencils on being drawn between the lips come to a fine point.

Pencil is also an instrument used in drawing, writing, &c. made of long pieces of black-lead, or red chalk, placed in a groove cut in a slip of cedar, on which other pieces of cedar being glued, the whole is planed round, and one of the ends being cut to a point, it is fit for use.

PENDULUM, in mechanics, denotes a heavy body so suspended that it may vibrate, or swing backwards and forwards about a fixed point by the action of gravity.

The vibrations of a pendulum are called its oscillations. A pendulum, therefore, is any body, B, Plate XLII. fig. 1, suspended upon, and moving about a fixed point, A, as a centre. The nature of a pendulum consists in the following particulars: 1. The times of the vibrations of a pendulum, in very small arches, are all equal. 2. The velocity of the bob, in the lowest point, will be nearly as the length of the chord of the arch which it describes in the descent. 3. The times of vibration in different pendulums, A B, A C, are as the square roots of the times of their vibrations. 4. The time of one vibration is to the time of the descent, through half the length of the pendulum, as the circumference of a circle to its diameter. 5. Whence the length of a pendulum, vibrating seconds, will be found 39.2 inches nearly; and that of an half second pendulum 9.8 inches. 6. An uniform homogeneous body B G, fig. 2, has a rod, staff, &c. which is one third part longer than a pendulum A D, will vibrate in the same time with it. See fig. 3.

From these properties of the pendulum we may discern its use as an universal chronometer, or regulator of time, as it is used in clocks, and such-like machines.

By this instrument also we can measure the distance of a ship, by measuring the interval of time between the fire and the sound of the gun. also the distance of a cloud, by numbering the seconds, or half-seconds, between the lightning and thunder; thus, suppose between the lightning and thunder, we number 10 seconds; then, because sound passes through 1142 feet in one second, we have the distance of the cloud equal to 11.420 feet. Again, the height of any room, or other object, may be measured by a pendulum vibrating from the top thereof. Thus, suppose a pendulum from the height of a room vibrates once in three seconds; then say, as 1 is to the square of 3, viz. 9, so is 39.2 to 352.8 feet, the height required. Lastly, by the pendulum we discover the different force of gravity on different parts of the earth's surface, and thence the true figure of the earth.

The following is a brief description of what is commonly termed the *gridiron* pendulum.—Instead of one rod, this pendulum is composed of any convenient odd number of rods, as five, seven, or nine: being so connected, that the effect of one set of them counteracts that of the

other set; and therefore, if they are properly adjusted to each other, the centres of suspension and oscillation will always be equidistant.

Fig. 4. represents a gridiron pendulum composed of nine rods, steel and brass alternately. The two outer rods, A B, C D, which are of steel, are fastened to the cross pieces A C, B D by means of pins. The next two rods, E F, G H, are of brass, and are fastened to the lower bar BD, and to the second upper bar E G. The two following rods are of steel, and are fastened to the cross bars E G and I K. The two rods adjacent to the central rod being of brass, are fastened to the cross pieces I K and L M; and the central rod to which the ball of the pendulum is attached, is suspended from the cross piece L M, and passes freely through a perforation in each of the cross bars I K, B D. From this disposition of the rods, it is evident that, by the expansion of the extreme rods, the cross piece B D, and the two rods attached to it, will descend: but since these rods are expanded by the same heat, the cross piece E G will consequently be raised, and therefore also the two next rods; but because these rods are also expanded, the cross bar I H will descend: and by the expansion of the two next rods, the piece L M will be raised a quantity sufficient to counteract the expansion of the central rod. Whence it is obvious, that the effect of the steel rods is to increase the length of the pendulum in hot weather, and to diminish it in cold weather, and that the brass rods have a contrary effect upon the pendulum. The effect of the brass rods must, however, be equivalent not only to that of the steel rods, but also to the part above the frame and spring, which connects it with the cock, and to that part between the lower part of the frame and the centre of the ball.

The gridiron pendulum was the invention of Mr. John Harrison, a very ingenious artist, and celebrated for his invention of the watch for finding the difference of longitude at sea, about the year 1725, and of several other time-keepers and watches since that time; for all which he received the parliamentary reward of between £20,000 and £30,000.

Pendulum, *royal*, a name used among us for a clock, whose pendulum swings seconds, and goes eight days without winding up; shewing the hour, minute, and second. The numbers in such a piece are thus calculated: First cast up the seconds in twelve hours, which are the beats in one turn of the great wheel: and they will be found to be $43200 = 12 \times 60 \times 60$. The swing-wheel must be 30, to swing 60 seconds in one of its revolutions; now let the half of 43200, viz. 21600, be divided by 30, and the quotient will be 720, which must be separated into quotients. The first of these must be 12. for the great wheel, which moves round once in 12 hours. Now 720 divided by 12, gives 60; which may also be conveniently broken into two quotients, as 10 and 6, or 12 and 5, or 8 and $7\frac{1}{2}$, which last is most convenient; and if the pinions are all taken 8, the work will stand thus:

$$\begin{array}{rrl} 8\,) & 96 & (\ 12 \\ 8\,) & 64 & (\ 8 \\ 8\,) & 60 & (\ 7\frac{1}{2} \\ \hline & & \ \ 30 \end{array}$$

According to this computation, the great wheel will go round once in 12 hours, to shew the hour; the next wheel once in an hour, to shew the minutes: and the swingwheel once in a minute, to shew the seconds.

PENELOPE, a genus of birds of the order of gallinæ; the characters of which are: the beak is bare at the base; the head is covered with feathers; the neck is quite bare; the tail consists of twelve principal feathers; and the feet are for the most part bare.

PENGUIN. See **Alca.**

PENNATULA, or **Sea-pen**, a genus of zoophyte, which, though it swims about freely in the sea, approaches near to the gorgonia. This genus has a bone along the middle of the inside, which is its chief support; and this bone receives the supply of its osseous matter by the same polype-mouths that furnish it with nourishment. Linnæus reckons seven species.

PENNY, formerly a silver, but now a copper coin.

The penny was the first silver coin struck in England by our Saxon ancestors, being the 240th part of their pound, and its true weight was about 22½ grains troy.

Penny-weight, a troy weight, being the 20th part of an ounce, containing 24 grains; each grain weighing a grain of wheat gathered out of the middle of the ear, well dried.

PENTAGON, in geometry, a figure having five sides, and five angles.

PENTAGRAPH, or **Parallelogram**, an instrument whereby designs of any kind may be copied in any proportion, without the operator being skilled in drawing.

The common pentagraph, however, it must be acknowledged, is an exceedingly imperfect instrument in practice, so much so that artists seldom make any use of it. There have been some improvements on it of late, and one in particular by Harris of London; but in this the work is complex, and the price necessarily high. This latter, instead of being fastened to the table when in use, is delicately suspended in an elevated frame, by which means the artist can regulate the pressure of the point employed in tracing with the utmost exactness.

An instrument for copying with great correctness, simple in its construction, and at a moderate price, is still a desideratum; and perhaps the nearest approach to this yet made, i late invention of Professor Wallace of the university of Edinburgh, and to which he has given the name of *Eidograph*, or *form copier*, a description of which may be seen in the Supplement to the Encyclopædia Britannica, and in the Glasgow Mechanics' Magazine, vol. i. p. 242.

PENTAMETER, in ancient poetry, a kind of verse consisting of five feet, or metres, whence the name.

PENTANDRIA, in botany, one of Linnæus's class of plants, the fifth in order; the characters of which are, that all the plants comprehended in it have hermaphrodite flowers, with five stamina or male parts in each; they are subdivided into orders, which are denominated monogynia, digynia, trigynia, &c. according as there are one, two, three, &c. pistils, or female parts, in each flower.

PENTAPETES, a genus of the dodecandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th

order, columniferæ. There is but one species known in the gardens of this country, viz. the phœnicia, with halbert-pointed, spear-shaped, sawed leaves. It is an annual plant, a native of India.

PENTHORUM, a genus of the pentagynia order, in the pentandria class of plants. The calyx is quinquefied; there are either five petals or none; the capsule is five-pointed and quinquelocular. There is one species.

PENTSLEMON, a genus of the didynamia angiospermia class and order. The calyx is five leaved; the corolla bilabiate, ventricose; rudiment of a 5th stamen, bearded above; capsules two-celled. There are two species.

PENUMBRA, in astronomy, a partial shade observed between the perfect shadow and the full light in an eclipse.

PEPLIS, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 17th order calycanthemæ. The perianthium is campanulated; the mouth cleft in twelve parts; there are six petals inserted into the calyx; the capsule is bilocular. There are two species, creeping plants.

PEPPER. See Piper.

PERAMBULATOR, in surveying, an instrument for measuring distances, called also pedometer, way-wiser, and surveying wheel.

Plate XLI, AA, fig. 5, is a wheel of mahogany, tired with iron, and made very strong; its circumference must be exactly ninety-nine inches, or half a pole. This is placed so as to turn round in an opening cut in the piece BD, which forms the frame. In the arm B, a groove is cut from the centre of the wheel to the dial *b*; the end of the spindle comes through the wood into this groove, and has a small crown-wheel of eight teeth upon it. This works another wheel of eight teeth fixed on a long spindle, which conveys motion from the wheel beneath to the dial *b*. The groove containing this spindle has a slip of wood screwed over it, to keep out dirt, &c.; and the end of this spindle has a square hole in it, into which is put the square end of the spindle *a*, fig. 6. This has an endless screw *d* upon it, which works a worm wheel *e* of twenty four teeth, having a pinion of twelve beneath it; and below this has a wheel *f* of thirty-six. The pinion works the wheel *g* of forty: and the wheel *f* turns the pinion *h* of twelve, whose spindle carries the short hand of the dial, fig. 7. The arbour of the wheel *g* comes up through the dial, and has the hand F on it; as also a pinion of eight, which turns *g* of sixty-four. In the arbour of the wheel *h*, is a pinion *i* of six, taking into *k* of seventy-two; this is here supposed to be half broken away, to shew the wheels beneath. The spindle of this is hollow, and is put over the arbour of the wheel *g*; and carries the hand G. HHHH are four pillars, by which the two plates forming the frame for the wheels are held together. The wheel *g* is not fixed fast to its spindle, but is held between a brass plate *l* and another beneath; the friction of these causes the wheel to turn the hand, and at the same time leaves the hand at liberty to be set without moving the wheels. The plate *l* has a pin *n* fixed in it; which pin takes against a projecting part of the handle of the hammer *m*, so as to lift it up when the plate is turned, and let the spring *o* through *w* against the bell K.

When any distance is to be measured by this machine, the operator takes hold of the handle, and wheels it along in as straight a line as he can. The circumference of the wheel being ninety-nine inches (or half a pole), and the two wheels in the piece being equal, the screw *d* will turn once in each turn of the great wheel, or twice for every pole the machine is wheeled. This screw must be so cut that the great wheel must turn twenty-four times for one turn of the wheel *e*, and also the wheel *f* on the same spindle as this must turn a pinion *h* of one-third of its number of teeth. The short hand on the dial which it carries will for every revolution require eight turns of the great wheel, = four poles, = one chain. The circle is divided into 100 parts, each = one link. The pinion of twelve on the arbour of the wheel *e*, turning once for twenty-four turns of the great wheel, makes the wheel *g* require for each revolution eighty turns of the great wheel, or for the machine to be wheeled ten chains (or turns of the short hand) = 40 poles (as the circle of its hand is divided), = one furlong: and at each revolution of this wheel, the hammer *m* will strike the bell K. The pinion of eight on the arbor of the wheel *g*, works *h* of sixty-four; and its pinion *i* turns K of seventy-two; the result of which will be, that the hand on the spindle of *k* will require for each revolution 7680 turns of the great wheel, or for the machine to be wheeled 3840 poles, = 960 chains or turns of the short hand, = 96 furlongs or turns of the hand F and strokes on the bell, = twelve miles as the dial is divided.

PERCA, Perch, a genus of fishes of the order thoracici; the generic character is, teeth sharp, incurvate; gill-covers triphyllous, scaly, serrated; dorsal fin spiny on the fore part; scales (in most species) hard and rough.

PERCUSSION, in mechanics, the impression a body makes in falling or striking upon another, or the shock of two bodies in motion. See Motion.

Percussion is either direct or oblique; direct, when the impulse is given in a line perpendicular to the point of contact; and oblique, when it is given in a line oblique to the point of contact.

PERENNIAL, in botany, is applied to those plants whose roots will abide many years, whether they retain their leaves in winter or not; those which retain their leaves are called evergreens; but such as cast their leaves, are called deciduous.

PERGALESIA, a genus of the pentandria digynia class and order. Contorted nect. surrounding the genitals with five-sagittated cups; corolla salver-shaped. There are five species, twining plants of the Cape, &c.

PERIANTHIUM. See Botany.

PERICARDIUM. See Anatomy.

PERICARPIUM, among botanists, a covering or case for the seeds of plants. See Botany.

PERICRANIUM. See Anatomy.

PERIGÆUM, perigee. See Astronomy

PERIHELIUM. See Astronomy.

PERILLA, a genus of the class and order didynamia gymnospermia. The calyx uppermost; segment very short; stamina distant styles two, connected. There is one species an annual of the East Indies.

PERIMETER, in geometry, the bounds of

limits of any figure or body. The perimeters of surfaces or figures are lines, those of bodies are surfaces. In circular figures, instead of perimeter, we say circumference, or periphery.

PERINÆUM, or **Perineum**. See Anatomy.

PERIOD, in astronomy, the time taken up by a star or planet in making a revolution round the sun; or the duration of its course till it returns to the same point of its orbit. See Astronomy.

Period. See Chronology.

Period, in grammar, denotes a small compass of discourse, containing a perfect sentence, and distinguished at the end by a point, or full stop, thus (.): and its members or divisions marked by commas, colons, &c.

PERIŒCI. See Geography.

PERIOSTEUM. See Anatomy.

PERIPHERY, in geometry, the circumference of a circle, ellipsis, or any other regular curvilinear figure. See Circle, &c.

PERJURY, is a crime committed when a lawful oath is administered, by any one who has authority, to a person in any judicial proceeding, who swears wilfully, absolutely, and falsely, in a matter material to the issue or cause in question, by his own act, or by the subornation of others. To constitute perjury, it is essential that the oath is wilfully taken; that it is in a judicial proceeding, or some other public proceeding of a similar nature: the oath must be taken before persons lawfully authorized to administer it, and also by a person sworn to depose the truth; it must also be taken absolutely and directly, and upon something material, to the point in issue.

PERIWINKLE. See Turbo.

PERMIT, a licence or warrant for persons to pass with or sell goods, having paid the duties of customs and excise.

PERMUTATION *of quantities*, in algebra, the same with combination. See Combination.

PERORATION, in rhetoric, the epilogue, or last part of an oration, wherein what the orator had insisted on through his whole discourse, is urged afresh with greater vehemence and passion. The peroration consists of two parts: 1. Recapitulation, wherein the substance of what was diffused throughout the whole speech is collected briefly, and cursorily, and summed up with new force and weight. 2. The moving the passions, which is so peculiar to the peroration, that the masters of the art call this part *sedes affectuum*.

PEROXIDE, in chemistry, signifies the maximum of oxidizement. See Oxide.

PERPENDICULAR. See Geometry.

PERPETUITY, in annuities, the number of years' purchase to be given for an annuity which is to continue for ever. It is found by dividing 100*l.* by the rate of interest.

PERRY, a drink made of pears in the same manner as cyder is made from apples. See Cyder.

PERSECUTION, is any pain or affliction which a person designedly inflicts upon another; and, in a more restrained sense, the sufferings of Christians on account of their religion. Historians usually reckon ten general persecutions, the first of which was under the emperor Nero, thirty-one years after our Lord's ascension; when that emperor having set fire to the city of Rome, threw the odium of that execrable action on the Christians, who under that pretence were wrapped up in the skins of wild beasts, and worried and devoured by dogs; others were crucified, and others burnt alive. The second was under Domitian, in the year 95. In this persecution St. John the apostle was sent to the isle of Patmos, in order to be employed in digging in the mines. The third began in the third year of Trajan, in the year 100, and was carried on with great violence for several years. The fourth was under Antoninus the philosopher, when the Christians were banished from their houses, forbidden to shew their heads, reproached, beaten, hurried from place to place, plundered, imprisoned, and stoned. The fifth began in the year 197, under the Emperor Severus. The sixth began with the reign of the Emperor Maximinus in 235. The seventh, which was the most dreadful persecution that had ever been known in the church, began in the year 250, in the reign of the emperor Decius, when the Christians were in all places driven from their habitations, stripped of their estates, tormented with racks, &c. The eighth began in the year 257, in the fourth year of the reign of the emperor Valerian. The ninth was under the emperor Aurelian, A. D. 274, but this was very inconsiderable; and the tenth began in the nineteenth year of Dioclesian, A.D. 303. In this dreadful persecution, which lasted ten years, houses filled with Christians were set on fire, and whole droves were tied together with ropes, and thrown into the sea.

PERSIAN *wheel*, an engine, or wheel, turned by a rivulet, or other stream of water, and fitted with open boxes at its cogs, to raise water for the overflowing of lands, or other purposes.

PERSON, in grammar, a term applied to such nouns or pronouns, as being either prefixed or understood, are the nominatives in all inflections of a verb: or it is the agent or patient in all finite and personal verbs.

PERSONAL GOODS. See Chattels.

PERSONATE, is the representing a person by a fictitious or assumed character, so as to pass for the person represented. Personating bail, is by stat. 21 Jac. I, c. 26, a capital felony. By various other statutes, personating seamen entitled to wages, prize-money, &c. is also a capital felony.

PERSPECTVE, is the art of drawing on a plane surface, in outline, the resemblance of any object, as that object itself would appear to the eye from any distance and situation, real or imaginary. In the following short article on the subject we can only lay down a few general principles for the assistance of the young student, who will do well to consult the excellent treatises of Brook, Taylor, Nicholson, Ferguson, and the short, but superior, practical treatise on perspective by Mr. J. Varley, of London.

The student is supposed to be tolerably well acquainted with geometry, without the knowledge of which his progress and success in the practical part of perspective must be slow, and attended with great uncertainty. Before proceeding to the practical part of this science, it may be of importance to explain some of the technical terms used by artists in regard to it. And first, the horizontal line is that supposed to be drawn parallel to the horizon through the eye of the spectator; or rather it is a line which separates the heaven from the earth, and which

limits the sight. Thus, A, B, fig. 1, Plate XLIII, are two pillars below the horizontal line CD, by reason the eye is elevated above them; in fig. 2, they are said to be equal with it; and in fig. 3, raised above it. Thus, according to the different points in view, the objects will be either higher or lower than the horizontal line. The point of sight, A, fig. 4, is that which makes the central ray on the horizontal line; or, it is the point where all the other visual rays, D, D, unite. The points of distance, C, C, are points set off in the horizontal line at equal distances on each side of the point of sight, A; and, in the same figure, BB represents the base line, or fundamental line; EE is the abridgement of the square, of which D, D, are the sides; F, F, the diagonal lines, which go to the points of distance C, C. Accidental points, are those where the objects end: these may be cast negligently, because neither drawn to the point of sight, nor to those of distance, but meeting each other in the horizontal line. The point of direct view, or of the front, is when we have the object directly before us; in which case, it shews only the foreside; and, if below the horizon, a little of the top, but nothing of the sides, unless the object is polygonous. The point of oblique view, is when we see an object aside of us, and, as it were, aslant, or with the corner of the eye; the eye, however, being all the while opposite to the point of sight: in which case, we see the object laterally, and it presents to us two sides or faces. The practice is the same in the side-points, as in the front points; a point of sight, points of distance, &c. being laid down in the one as well as in the other.

Parallel perspective is where the picture is supposed to be so situated, as to be parallel to the side of the principal object in the picture, as a building for instance.

Oblique perspective, is when the plane of the picture is supposed to stand oblique to the sides of the objects represented, in which case the representations of the lines upon those sides will not be parallel among themselves, but will tend towards their vanishing point.

A bird's-eye view, is a view supposed to be taken in the air, looking down upon the object, and differs from the usual way of drawing perspective views, in supposing the horizontal line to be raised much higher.

When an object is to be drawn in perspective, all its parts must be measured, so that we may be able to lay them down from a scale of equal parts.

Having determined whether it is to be parallel or oblique perspective, the first thing to be drawn is the horizontal line, which is to be put parallel to the bottom of the drawing, and as high above it as the height of a man's head, or five feet six inches, as HG, fig. 5, which is five feet six inches above the bottom of the house. Next, determine on the centre of the picture G, which must be placed so as to leave convenient room for the representation. Fix on C the nearest corner of the object, and draw the perpendicular CB: lay off CD equal to the length of the building, and draw DA and AB. From C, the nearest corner, draw CG to the centre of the picture. CG now contains the line which represents the bottom of the end of the house; but this is an indefinite representation, of which we do not yet know the exact length. The method of determining this is as follows: Continue the line DC to I, and make CI equal to the width of the house. From G, the centre of the picture, lay off G K equal to the distance of the picture, the choosing of which must be regulated by taste. Draw IK, cutting CG in F; then is CF the exact width of the house in perspective, which was equal to CI. To find the middle of this end of the house, you cannot divide it by your compasses, because the farthest half will appear less than the nearer; but if you divide CI into two equal parts in L, and draw LK, it will cut CF into two equal parts perspectively. Or it may be found more simply thus: having drawn the lines BE and CF to the centre of the picture, draw the diagonals EC, BF, crossing each other in M, and raise the perpendicular MN, which is in the middle of the gable end.

To find the height of the gable, lay its actual height above BE, upon the corner line BC continued, as BO, and draw OG; this crossing the perpendicular MN, gives N the point of the gable. The top of the chimney must be drawn in the *same* manner, by laying its *real* height, taken from a scale, on OP; and drawing PG, lay off L*m* and L*n*, each equal to half the width, and draw from these points to the distance-point K; this will cut the bottom of the house CF, in the points *a* and *p*; from these draw perpendiculars, which will give the perspective width of the chimney. To obtain its thickness, lay off PQ equal to its thickness, and draw QG; then drawing from *a* the line *ab*, you obtain the exact width of the chimney. From *b* draw *bc*, and from *d* draw *dc*. The other end of the gable may be drawn by two different methods. The first is by supposing the front of the house transparent, and drawing the other end as if seen through it, in the same manner as the end we have described, by laying its width from D to R, and drawing to the distance-point K. By raising the perpendicular in the middle, you will meet the ridge-line from the other gable in *d*. The other method is as follows: through the centre of the picture G draw the line ST, upwards and downwards, and perpendicular to the horizontal line. Then continue the line of the roof B*d* till it meets ST in S. From A draw AS, which will give the other gable, and S will be the vanishing-point for all lines parallel to B*d* and A*d*; if NE is continued in like manner, it will give T for its vanishing-point. The doors and windows on the side ABCD are laid down from a scale, because that side being parallel to the picture, does not vary from its geometrical delineation, except shewing the thickness of the reveals, or edges of the doors and windows. If there had been any windows in the side BEFC, they would be drawn in perspective by the same method that was used for finding the width of the house and the middle of the end, viz. by laying off the actual dimensions from C upon CI, and drawing from these points to the distance-point K, which would transfer these divisions to the bottom of the house CF, and then perpendiculars might be drawn upwards.

PROBLEM I.

To divide a line in perspective which is parallel to the horizon, and which tends to a vanishing-point, into any number of equal parts; or to divide it into any required proportion

Let A B be the li [illegible] ishing point C, fig 6; and first let it be required to divide that line into six equal parts. Let C D be the horizontal line, and A E the ground line, drawn parallel to it. Lay off at pleasure, C D for the distance of the picture, if C is the centre of the picture. Draw a line from D, touching the end B of the line to be divided: draw D B E, cutting the ground-line in E. Then A E represents the actual dimensions of the line A B, which is seen in perspective. Here it may be observed, that this gives a rule also for finding the real length of any line which tends to a vanishing point. Divide A E into the same number of equal parts into which you proposed to divide the given line A B; as A 1 1 2, 2 3, &c. Then from these different divisions draw lines to D, cutting the line A B in *a*, *b*, *c*, *d*, &c. which will represent the required number of equal parts, but diminishing in size as they are farther removed from the eye. If it is wished to divide the line A B into any number of unequal parts, or to lay off doors, windows, &c. upon it, the line A E, found as before, must be divided into the required proportion, and lines drawn from those to D will give the required divisions on A B, from which perpendiculars may be drawn for the doors, windows, &c.

Problem 2.

To draw a circle in perspective.

The perspective representation of every circle is an ellipsis, when the eye is without the circle. This is obvious, because the rays from the circumference of the circle to the eye form an *oblique cone*. But those who are acquainted with conic sections, know that every section of a cone, whether right or oblique, is a true ellipsis, except when the section is taken subcontrary to its base, a situation which happens so rarely in drawings as to be altogether disregarded, and the section of a cone, or the perspective of a circle, is in all cases considered a perfect ellipsis.

The most correct and easy method of drawing an ellipsis is, to find the transverse and conjugate axes; the curve is then completed by a trammel, or the hand. But as it is difficult to find the transverse and conjugate axes of the ellipsis, which are the perspective, if the circle to be put in perspective be small, describe a square about it. Draw first the diagonals of the square fig. 7, and then the diameters *h a* and *d e*, cutting one another at right angles; draw the straight lines *f g* and *b c* parallel to the diameter *d e*. Through *b* and *f*, and *c* and *g*, draw straight lines meeting D E, the ground of the picture in the points 3 and 4. To the principal V draw the straight lines I V, 3 V, 4 V, 2 V, and to the points of distance L and K, 2 L and 1 K. Lastly, join the points of intersection *a*, *b*, *d*, *f*, *h*, *g*, *e*, *c*, by the arcs *a b*, *e d*, *d f*, and *a b d f h g e c a* will be the circle in perspective. In this process, it is of consequence to know that the curve you trace is a regular ellipsis: for though you cannot easily ascertain the axes *exactly*, yet you may *very nearly*; and the eye soon discovers whether the curve drawn be that of a regular ellipsis.

Problem 3.

To represent a double cross in perspective.

In fig. 8, let A B C D and E F G H be two [illegible] ve squares, [illegible] nd parallel to one another, the uppermost directly above the lowermost, drawn by the rules already laid down, and as far asunder as is equal to the given height of the upright part of the cross; S being the point of sight, and P the point of distance, in the horizon P S taken parallel to A D.

Draw A E, D H, and C G; then A E H D and D H G C shall be the two visible sides of the upright part of the cross; of which, the length A E is here made equal to three times the breadth E H.

Divide D H into three equal parts, H I, I K, and K D. Through these points of division, at I and K, draw M O and P R parallel to A D: and make the parts M N, I O, P Q, K R, each equal to H I: then draw M P, and O R parallel to D H.

From M and O, draw M S and O S to the point of sight S; and from the point of distance P draw P N, cutting M S in T: from T draw T U parallel to M O, and meeting O S in U and you will have the uppermost surface M T U of one of the cross pieces of the figure.—From R, draw R S to the point of sight E; and from U draw U V parallel to O R; and O U V R shall be the perspective square end next the eye of that cross part.

Draw P M *x* (as long as you please) from the point of distance P, through the corner M; lay a ruler to N and S, and draw X N from the line P *x*:—then lay the ruler to I and S, and draw Y Z S.—Draw X Y parallel to M O, and make X W and Y B equal and perpendicular to X Y: then draw W B parallel to X Y, and W X Y B shall be the square visible end of the other cross part of the figure.

Draw B K toward the point of sight S; and from U draw V P to the point of distance P, intersecting Y S in Z: then, from the intersection Z draw Z *a* parallel to M O, and Z *b* parallel to H D, and the whole delineation will be finished.

This done, shade the whole, as in fig. 9, and you will have a true perspective representation of a double cross.

Fig 10 shows the method of drawing a building, or other object, in oblique perspective. A B is the horizontal line, and C D the ground line, parallel to it as before. Here neither of the sides of the house is parallel to the picture; but each goes to its respective vanishing-point. Having fixed on the nearest corner E, draw E B, at pleasure, for one side, and choose any point F for the centre of the picture; then, to find the other side, lay off F G equal to the distance of the picture, which as before depends upon taste only; draw B G, and G A perpendicular to B G cutting the horizontal line in A, the other vanishing point. Draw now E A for the other side. To cut off the several widths of the two sides of the house, which as yet are only drawn to an indefinite extent, two distance points must be laid down, viz. one for each vanishing-point. To do this, extend the compasses from B to G, and lay the distance taken in it from B to H which will give H for the distance-point of B, and which is to cut off all the divisions on the side E B. Also extend the compasses from A G, and lay down A I. I is the distance point of A, and is used for transferring all divisions upon the side E A from the ground-line G E. These points and lines being adjusted, the process is not much different from parallel

perspective; only here equal divisions on each side of the building, as doors, windows, diminish as they recede, in the same way as on the side BEFC, fig. 10. Lay the real length of the side EL, taken from the same scale used for laying down the horizontal line, and lay it down on the ground-line, from E to C, and draw CI, cutting off EL for the perspective length of the building. For the other side of the house, lay its width down in the same manner, from E to D, and draw DH, cutting off EN for the perspective width. Raise the perpendiculars EM, LK, and NO, for the three angles of the house. Lay the height of the building upon the corner that comes to the ground-line, as EM, and draw MK and MO to their several vanishing points. Also lay all the heights of the doors and windows, and other divisions, upon EM, and draw them to the vanishing points A and B. To lay down the widths of the doors and windows, put their actual widths upon CE, and draw from them to the distance-point I, which cuts off all divisions upon the side LE, and then raise the perpendiculars. The gable-end is found exactly in the same manner as has been described, only taking care to use the proper distance-point H. The manner of finding the width of the chimney is different. Lay off *ba* for the height of the chimney above the top of the gable, and draw *ac* parallel to the horizontal line; then put *ac* equal to the actual thickness of the chimney, and draw *ad* to the vanishing-point A; draw also *cd* to the distance-point I, cutting off *ad* in *d*: then having drawn *ef* from the nearest corner of the chimney, which was found as in fig. 10, draw *df* to the vanishing-point B, cutting off *ef* for the exact perspective width.

Perspective-plane, is the glass or other transparent surface, supposed to be placed between the eye and the object, perpendicularly to the horizon. It is sometimes called the section, table, or glass.

PERSPIRATION, in medicine, the evacuation of the juices of the body through the pores of the skin. Perspiration is distinguished into sensible and insensible; and here sensible perspiration is the same with sweating, and insensible perspiration that which escapes the notice of the senses; and this last is the idea affixed to the word *perspiration* when used alone.

PERSPICUITY, properly signifies the property which any thing has of being easily seen through; hence it is generally applied to such writings or discourses as are easily understood.

PERU, *Balsam of.* This substance is obtained from the myroxylon peruiferum, which grows in the warmer parts of South America. The tree is full of resin, and the balsam is obtained by boiling the twigs in water. It has the consistency of honey, a brown colour, an agreeable smell, and a hot acrid taste.

PETAL, among botanists, an appellation given to the flower-leaves, in opposition to folia, or common leaves of the plant.

PETARD, in the art of war, a metalline engine, somewhat resembling a high crowned hat. Its use is in a clandestine attack to break down gates, bridges, barriers, &c. to which it is hung; and this it does by means of the wooden plank. It is also used in counter-mines to break through the enemy's galleries, and give their mines vent.

PETITIO PRINCIPII, in logic, the taking a thing for true, and drawing conclusions from it as such, when it is really false, or at least wants to be proved, before any inferences can be deduced from it.

PETITION. No petition to the king, or to either house of parliament, for any alteration in church or state, shall be signed by above twenty persons, unless the matter thereof is approved by three justices of the peace, or the major part of the grand jury in the county; and in London by the Lord Mayor, aldermen, and common council: nor shall any petition be presented by more than ten persons at a time.

PETRIFACTION, in natural history, denotes the conversion of wood, bones, and other substances, principally animal or vegetable, into stone.

Petrifactions. Stony matters deposited either in the way of incrustation, or within the cavities of organised substances, are called petrifactions. Calcareous earth being universally diffused and capable of solution in water, either alone, or by the medium of carbonic acid or sulphuric acid, which are likewise very abundant, is deposited whenever the water or the acid becomes dissipated. In this way we have incrustations of limestone or of selenite in the form of stalactites or dropstones from the roofs of caverns, and in various other situations.

The most remarkable observations relative to petrifactions are thus given by Kirwan:—

1. That those of shells are found on, or near, the surface of the earth; those of fish deeper; and those of wood deepest. Shells in specie are found in immense quantities at considerable depths.

2. That those organic substances that resist putrefaction most, are frequently found petrified; such as shells and the harder species of woods: on the contrary, those that are aptest to putrefy are rarely found petrified; as fish, and the softer parts of animals, &c.

3. That they are most commonly found in strata of marle, chalk, limestone, or clay, seldom in sandstone, still more rarely in gypsum; but never in gneiss, granite, basaltes, or shorle; but they sometimes occur among pyrites, and ores of iron, copper, and silver, and almost always consist of that species of earth, stone, or other mineral that surrounds them, sometimes of silex, agate, or cornelian.

4. That they are found in climates where their originals could not have existed.

5. That those found in slate or clay are compressed and flattened.

PETROLEUM. See Bitumen.

PETROMYZON, the *lamprey*, a genus of fishes belonging to the class of amphibia nantes. It has seven spiracula at the side of the neck, no gills, a fistula on the top of the head, and no breast or belly fins. There are eight species, distinguished by peculiarities in their back fins.

PETUNSE. See Porcelain.

PEWTER, which is commonly called *etain* in France, and generally confounded there with true tin, is a compound metal, the basis of which is tin. The best sort consists of tin alloyed with about a twentieth or less of copper or other metallic bodies, as the experience

of the workmen has shown to be the most conducive to the improvement of its hardness and colour, such as lead, zinc, bismuth, and antimony. There are three sorts of pewter, distinguished by the names of plate, trifle, and ley-pewter. The first was formerly much used for plates and dishes; of the second are made the pints, quarts, and other measures of beer; and of the ley-pewter, wine measures and large vessels. The best sort of pewter consists of 17 parts of antimony to 100 parts of tin; but the French add a little copper to this kind of pewter.

PHAETON, in ornithology, a genus of birds belonging to the order of anseres, the characters of which are: The bill is sharp, straight, and pointed; the nostrils are oblong, and the hinder toe is turned forward. There are two species, viz.

1. The *demersus*, or red-footed pinguin, has a thick, arched, red bill; the head, hind part of the neck, and the back, of a dusky purplish hue, and breast and belly white; brown wings, with the tips of the feathers white; instead of a tail, a few black bristles; and red legs. It is found on Pinguin isle, near the Cape of Good Hope, is common all over the South Seas, and is about the size of a goose.

2. The *ethereus*, or tropic bird, is about the size of a partridge, and has very long wings. The bill is red, with an angle under the lower mandible. The eyes are encompassed with black, which ends in a point towards the back of the head. Three or four of the larger quill-feathers towards their ends are black, tipped with white; all the rest of the bird is white, except the back, which is variegated with curved lines of black. The legs and feet are of a vermilion red. The toes are webbed. The tail consists of two long straight narrow feathers, almost of equal breadth from their quills to their points.

PHALÆNA, *moth*, a genus of insects of the order lepidoptera: the generic character is; antennæ cetaceous, gradually lessening from base to tip; wings (when sitting) generally deflex (flight nocturnal.) This genus, like that of papilio, containing a vast number of species, is divided into assortments, according to the different habits of the animals.

PHALLUS, the morel, a genus of the order of fungi, belonging to the cryptogamia class of plants. The fungus is reticulated above, and smooth below. There are three species.

PHANTASMAGORIA, or the raising of spectres, is a term applied to the exhibition of an optical apparatus similar to the magic lantern. See Optics.

PHARMACY, is the art of preparing, compounding, and preserving medicinals.

The preservation of medicines merely consists in the application of rules for collecting vegetable, animal, and mineral productions, at certain seasons, or under particular circumstances, and of ensuring them against the injuries they would suffer by exposure to light, heat, air, moisture, &c.; this, therefore, is the least extensive, and peculiar department of the pharmaceutic art. It is the preparation and composition of medicinals that constitute the principal objects of this science.

PHASEOLUS, *kidney-bean*, a genus of the diadelphia decandria class of plants, the corolla whereof is papilionaceous; the vexillum cordated, emarginated, and reclined with reflex sides; the alæ are roundish, of the same length with the vexillum, and stand upon long ungues; the carina is narrow, and revolves spirally in a contrary direction to the sun; the fruit is a long, straight, coriaceous, and obtuse pod; the seeds are oblong, compressed, and kidney-shaped. There are 21 species.

PHASES. See Astronomy.

PHASIANUS, the *pheasant*, in natural history, a genus of birds of the order gallinæ. Generic character: bill short, strong, and convex, head covered in some degree with carunculated flesh; legs generally with spurs. There are ten species.

Phasianus gallus, or the wild pheasant, inhabits the forests of India, and has been seen, indeed, by navigators, in almost all the Indian and South Sea islands.

Phasianus gallus, or the dunghill cock. The most interesting animal under this variety, is the game cock; which is found in greater perfection of vigour and courage in England, than in any other country; and the irascibility and jealousy of which has, in almost all ages, occasioned it to be employed in the brutal diversion of cock-fighting.

PHILOLOGY, a science, or rather assemblage of several sciences, consisting of grammar, rhetoric, poetry, antiquities, history, and criticism. Philology is a kind of universal literature, conversant about all the sciences, their rise, progress, authors, &c. It makes what the French call the *belles lettres*. In the universities it is called humanities. Anciently philology was only a part of grammar.

PHILOSOPHER, a person versed in philosophy; or one who makes profession of, or applies himself to, the study of nature and morality.

PHILOSOPHY, or the love of wisdom, is a term applied to the doctrines that have at different times, and by different men, been asserted and propagated in the world. Of these the following slight sketch may be of service to the young student.

1. *Pythagorean philosophy* was taught by the philosophers who adhered to the doctrines of Pythagoras, who flourished about 500 years before Christ. They taught that there is one God, an incorruptible and invisible Being, and therefore only to be worshipped with a pure mind; and that there is a relationship between the gods and man, which is supposed to have been borrowed from the Christian doctrine of Providence. They asserted a transmigration of souls, and therefore the immortality of the soul. They taught that virtue is harmony, health, and every good thing, and inculcated in an impressive manner the duties of children towards their parents. The disciples of this school were exhorted to cherish sentiments honourable to the female sex.

2. *Aristotelian philosophy.*—This was taught by Aristotle, and maintained by his followers; it was also called *peripatetic*. Aristotle was a disciple of Plato; but his system differed greatly from that of his master. Without enumerating his principles, it may be observed that most of them were false, and his reasonings inconclusive.

3. *Peripatetic philosophy*, so called from a sect of philosophers the followers of Aristotle.

Cicero tells us that Plato left two excellent disciples, Xenocrates and Aristotle, who founded two sects, who differed in name. The former called academics, because they held their conferences in the academy: the latter, who followed Aristotle, were called peripatetics, or walkers, because they disputed walking in the lyceum or school.

4. *Socratic philosophy.*—This comprised the doctrines and opinions with regard to morality and religion, maintained and taught by Socrates about 400 years before Christ. Socrates was one of the best and wisest persons in the heathen world. The first introduction of moral philosophy is ascribed to him. He it was that led men from the contemplation of the heavens to consider *themselves,* their own passions, opinions, faculties, duties, and actions. It was he who, when all the other philosophers boasted that they knew all things, first owned that he knew nothing but this, *that he knew nothing.* Socrates wrote nothing himself, yet almost all the sects of Greece refer their origin to his discipline. The genuine principles of his philosophy are stated in the Memorabilia of Xenophon. Plato by attributing to his master conceptions, sublime indeed, but evidently borrowed from, and embellished with the mythology of, the Pythagorean school, has rendered his writings on this point apocryphal.

5. *Platonic philosophy.*—This was founded by Plato, who lived about 350 years before Christ. It appears to have been drawn from traditions founded upon early revelations: from scattered fragments of the ancient patriarchal creed: and there is scarcely any thing good or commendable said of the Deity, but what he had from ancient creeds, which prevailed before the general defection to idolatry. Plato confesses that the Greeks borrowed their knowledge of the one infinite God from an ancient people, better and nearer to God than they. His account of man's state of innocence—that he was born of the earth—that he was naked—that he enjoyed a truly happy state—that he conversed with brutes—that a personage was expected, who would give mankind a model for devotion, &c.; in short, all parts of his philosophy bear evident marks of being derived from Revelation.

6. *Academic philosophy* was originally derived from Socrates and Plato, who taught in a grove near Athens, consecrated to the memory of Academus, an Athenian hero. Labour and caution in their researches, in opposition to rash and hasty decisions, were the distinguishing characteristics of the disciples of the ancient academy. The sceptical notions of Arcesilaus, Carneades, and the other disciples of the succeeding academics, were of a very opposite nature to those which were inculcated by Socrates and Plato.

7. *Cyrenaic philosophy,* so called from Aristippus of Cyrene, a disciple of Socrates. Their leading tenets were unfriendly to virtue and the welfare of society. This sect was afterwards divided into three branches, when it soon languished, and sunk into deserved obscurity.

8. *Epicurean philosophy,* so named from Epicurus the founder. The Epicureans have in all ages been decried for their morals and their attachment to the pleasures of sense; and in the common use of the word, Epicurean signifies an indolent, effeminate, and voluptuous person. But there were two kinds of Epicureans, the rigid and the remiss. The *rigid* were strictly attached to the sentiments of Epicurus, and placed all their happiness in the pure pleasures of the mind, resulting from the practice of virtue. The *remiss* placed all their happiness in pleasures of the body, in eating, drinking, &c. The former, who were the genuine Epicureans, called the others the sophists of their sect. Epicurus flourished more than 300 years before Christ.

9. *Stoic philosophy* includes the followers of Zeno; so called because Zeno used to teach under a portico or piazza. He is supposed to have borrowed many of his dogmata from the Phœnician philosophy, which was, in fact, taken from the Jewish. Many things also appear to be borrowed from the schools of Socrates and Plato. The morality of the Stoics was couched in paradoxes:—as, the wise man is void of all passion and perturbation of mind—that pain is no real evil—that a wise man is happy in the midst of the severest torture—that a wise man is always the same, and always joyful—that none but a wise man is free and rich, or ought to be esteemed or acknowledged as a king, magistrate, poet, or philosopher—that all wise men are great—that all things are a wise man's who is contented with himself—that wise men are the only true friends and lovers—that nothing ever happens to a wise man beyond expectation—that all good things are equal, and equally to be desired—and that goodness admits of no increase or diminution; with many others. They acknowledged one God, whom they called *mind, fate, Jupiter,* and believed that the human soul survived the body.

10. *Cynic philosophy.*—The disciples of this sect valued themselves upon a contempt of every thing, especially riches and estates, arts and sciences; all excepting morality. The founder of this sect was Antisthenes, a disciple of Socrates, nearly 400 years before Christ. He was called an ingenuous and sincere *dog,* it being the distinguished character of the Cynics to attack and bark at the wicked, and to defend and fawn on the good; hence they were called Cynics. Antisthenes had an academy not far from the gates of Athens. There is an affinity between the Stoics and the Cynics; but the former were more modest and reserved than the latter, who are said to have banished all shame. Diogenes was of this sect; he lived 380 years before Christ.

11. *Sceptic philosophy.*—The doctrines and opinions of the Sceptics, called also Pyrrhonism, from its author Pyrrho, who lived about 500 years before Christ. The ancient scepticism consisted in doubting of every thing, in affirming nothing, and in keeping the judgment in suspense on every thing. Socrates, as was before observed, used to say, 'I know nothing but this, that I know nothing:' which the Sceptics altered to this, 'I know nothing, not even this; that I know nothing.'

In concluding these observations on the ancient philosophy and philosophers, it may be observed that *Scripture* was the basis, or rather the chief source whence the heathens of Greece and Rome drew their fables;—they founded their tenets on the first principles of religion Their philosophy seemed but a prelude to that

conversion of them which God had so frequently predicted by his prophets. The truths of the Christian religion they thus inculcated to their disciples; and what is more remarkable, taught almost 400 years before the light of the gospel had shed its blessings on the world. Plato began to write immediately after the three last prophets that were in Israel. When the prophets ceased among the Jews, God raised these philosophers to illuminate the Gentiles. Thus many of the principles of the gospel were publicly taught at Athens. The philosophers instructed their scholars in the belief of one God; that they ought to love and serve him, and to endeavour to resemble him in holiness and righteousness; and that this God rewards humility, and punishes pride; with many other tenets nearly similar to those contained in the gospel.

PHLEBOTOMY, in surgery, the opening a vein with a proper sharp-edged and pointed instrument of steel, in order to let out a proper quantity of blood, either for the preservation, or recovery, of a person's health.

PHLOAS, a genus of vermes testacea; the animal an ascidia; shell bivalve, divaricate, with several lesser differently shaped accessory ones at the hinge; hinges recurved united by a cartilage: in the inside, beneath the hinge, is an incurved tooth. The inhabitants of this genus perforate clay, spongy stones and wood, while in the younger state; and as they increase in size, enlarge their habitation within, and thus become imprisoned. They contain a phosphorous liquor of great brilliancy in the dark, and which illuminates whatever it touches or happens to fall upon. There are 12 species.

PHLOMIS, the *sage-tree*, or *Jerusalem sage*, a genus of the gymnospermia order, in the didynamia class of plants. The calyx is angular; corolla, upper lip incumbent, compressed, villose. There are 22 species, all of which have perennial roots, and of many the stalks also are perennial.

PHOCA, *seal*, a genus of quadrupeds of the order feræ. The generic character is, fore-teeth in the upper jaw six, pointed, parallel, the exterior larger; in the lower jaw four, bluntish, parallel, distinct, equal canine teeth one on each side in both jaws, large, pointed; the upper ones distinct from the cutting-teeth, the lower from the grinders; grinders, five on each side above, six below, obtusely tricuspidated. There are about 19 species.

PHŒNICOPTERUS, or FLAMINGO, in ornithology, a genus of birds belonging to the order of grallæ. The beak is naked, toothed, and bent, as if it was broken; the nostrils are linear; the feet are palmated, and four-toed. There is but one species, viz. the Bahamensis of Catesby, a native of Africa and America.

This bird resembles the heron in shape, excepting the bill, which is of a very singular form. It is two years old before it arrives at its perfect colour, and then it is entirely red, excepting the quill feathers, which are black. A full-grown one is of equal weight with a wild duck; and when it stands erect, it is five feet high. The feet are webbed. The flesh is delicate, and most resembles that of a partridge in taste. These birds make their nests on hillocks in shallow water, on which they sit with their legs extended down, like a man sitting on a stool. They breed on the coasts of Cuba and the Bahama islands in the West Indies, and frequent salt water only.

PHŒNIX, the *great palm*, or *date-tree*, a genus of plants belonging to the order palmæ. The calyx is 3-parted; corolla 3-petalled; male stamina three; female pist. one, drupe ovate. There is only one species, viz. the dactylifera, or common date-tree, a native of Africa and the Eastern countries, where it grows to 50, 60, and 100 feet high.

PHOSPHATS, salts formed by the phosphoric acid, with the alkalis, earths, and metallic oxides. They may be distinguished by the following properties: 1. When heated with combustibles, they are not decomposed, nor is phosphorous obtained. 2. Before the blowpipe they are converted into a globule of glass, which in some cases is transparent, in others opaque. 3. Soluble in nitric acid without effervescence, and precipitated from that solution by lime-water. 4. Decomposed, at least partially, by sulphuric acid; and their acid, which is separated, when mixed with charcoal, and heated to redness, yields phosphorus. 5. After being strongly heated, they often phosphoresce.

The phosphats readily combine with an excess of acid, and form superphosphats.

The phosphats at present known amount to 12; two of which are triple salts.

PHOSPHITES, salts formed with the phosphorus acid united to the earths, alkalis, and metallic oxides. These salts may be distinguished by the following properties: 1. When heated, they emit a phosphorescent flame. 2. When distilled in a strong heat, they give out a little phosphorus, and are converted into phosphats. 3. They detonate when heated with nitrat or oxymuriat of potass, and are converted into phosphats. 4. They may be converted into phosphats by nitric and oxymuriatic acid. 5. They are fusible in a violent heat into glass. The phosphites at present known amount to eight.

PHOSPHORIC ACID. The base of this acid, or the acid itself, abounds in the mineral, vegetable, and animal kingdoms. In the mineral kingdom it is found in combination with lead, in the green lead ore; with iron, in the bog ores which afford cold short iron; and more especially with calcareous earth in several kinds of stones. Whole mountains in the province of Estremadura in Spain are composed of this combination of phosphoric acid and lime.

In the animal kingdom it is found in almost every part of the bodies of animals which are not considerably volatile. There is not, in all probability, any part of these organized beings which is free from it. It has been obtained from blood, flesh, both of land and water animals; from cheese; and it exists in large quantities in bones, combined with calcareous earth. Urine contains it, not only in a disengaged state, but also combined with ammonia, soda, and lime.

PHOSPHORUS. If phosphoric acid be mixed with 1-5th of its weight of powdered charcoal, and the mixture distilled at a moderate red heat, in a coated earthen retort, whose beak is partially immersed in a basin of water, drops of a waxy-looking substance will pass

over, and, falling into the water, will concrete into the solid called phosphorus. It must be purified, by straining it through a piece of chamois leather, under watm water. It is yellow and semitransparent. It is as soft as wax, but fully more cohesive and ductile. Its sp. gr. is 1.77. It melts at 90° F. and boils at 550 degrees.

When phosphorus is heated in the air to about 148°, it takes fire, and burns with a splendid white light, and a copious dense smoke. If the combustion take place within a large glass receiver, the smoke becomes condensed into snowy looking particles, which fall in a successive shower, coating the bottom plate with a spongy white efflorescence of phosphoric acid. This acid snow soon liquefies by the absorption of aqueous vapour from the air.

When phosphorus is inflamed in oxygen, the light and heat are incomparably more intense; the former dazzling the eye, and the latter cracking the glass vessel.

PHOSPHURETS, substances formed by an union of the alkalis, earths, and metallic oxides, with phosphorus. Thus we have phosphuret of lime, &c.

PHOTOMETER, an instrument intended to indicate the different quantities of light, as in a cloudy or bright day, or between bodies illuminated in different degrees. Mr. Leslie has invented an instrument of this kind, the essential part of which consists of a glass tube like a reversed syphon, whose two branches should be equal in height, and terminated by balls of equal diameter; one of the balls is of black enamel, and the other of common glass into which is put some liquid.

The motions of the liquor, which is sulphuric acid tinged red with carmine, are measured by means of a graduation, the zero is situated towards the top of the branch that is terminated by the enamelled ball. The use of this instrument is founded upon the principle, that when the light is absorbed by a body, it produces a heat proportional to the quantity of absorption. When the instrument is exposed to the solar rays, those rays that are absorbed by the dark colour, heat the interior air, which causes the liquor to descend at first with rapidity in the corresponding branch. But as a part of the heat which had introduced itself by means of the absorption is dissipated by the radiation, and as the difference between the quantity of heat lost, and that of the heat acquired goes on diminishing, there will be a point where these two quantities having become equal, the instrument will be stationary, and the intensity of the incident light is then estimated by the number of degrees which the liquor has run over.

The author of this ingenious instrument has pointed out its advantages in determining the progressive augmentation undergone by the intensity of the light, and the gradation in a contrary sense which succeeds to that progress, both from the beginning of the day to its end, and from the winter solstice to the end of the succeeding autumn. With the help of such an instrument one might also compare the action of rays of light in different countries of which some dart with sufficient constancy from a fine and serene sky, while others seem to be covered with a veil which dims and obscures their lustre.

PHRENOLOGY, from φρην *mind*, and λογος *a discourse*, is the name applied to a science which, though by no means new, has not till very recently attracted the attention of the public. Phrenology, says Mr. George Combe, in his excellent little work on the subject treats of the faculties of the human mind, and of the organs by which they manifest themselves; but it does not enable us to predict actions. Dr. Gall, a physician of Vienna, appears to have been the founder of the system, and for the first time delivered lectures on it in 1796 In 1800, Dr. J. G. Spurzheim began to study this doctrine under Dr. Gall; and in 1804 was associated with him in his labours. Since that time he has added much to the discoveries of Dr. Gall; and indeed to him we are principally indebted for the high ground on which the system stands in Britain at the present day.

This system, although yet in its infancy, promises to effect great things. Much alarm has been excited by it among those who are reckoned the great defenders of the Christian religion, as if its tendency were towards the foolish and gloomy doctrine of materialism: this, however, is only a strong proof that they have never examined the subject with sufficient care; or rather it is a proof of the insufficiency of their own system to afford satisfaction on topics of great interest to minds that are expanding by the benign influence of science. The subject of phrenology has met with the greatest encouragement in this country. In the city of Edinburgh, where there is a regularly organized society composed of men of respectability and superior talent; the reports of this society are regularly published, in addition to which they issue a Magazine, embracing discussions in any way suited to elicit information on the grand object of their researches.' We shall here present our readers with an abstract of the doctrine of phrenology, as exhibited in the most recent productions of its advocates, merely farther observing, that the general developement of the different organs is by a protuberance in that part of the head where they are respectively situated, and by the proportion which that protuberance bears to the rest of the skull and the adjoining organs. The numbers refer to the different regions of the map of the head as laid down by phrenologists. See plate XLIV.

1. **Amativeness.** The cerebellum is the organ of this propensity; it is situated between the maistoid process on each side, and the projecting point in the middle of the transverse ridge of the occipital bone: i. e. at the back of the neck or lower part of the head. The size is indicated by the thickness of the neck at these parts. *Function.* The sexual passions.

y.

2. **Philoprogenitiveness.** Above the middle part of the cerebellum, corresponding to the general protuberance of the occiput it is above amativeness. *Function.* The instinctive love of offspring in general. Parental affection.

3. **Concentrativeness.** Above philoprogenitiveness, and below self-esteem. *Function* The faculty of concentrating several powers t one object. Study.

4. **Adhesiveness.** On each side of concentrativeness, above philoprogenitiveness, and just above the lambdoidal suture. *Function.* The instinctive tendency to attach ourselves to others, to animals, or to objects. Friendship.

5. **Combativeness.** At the inferior and mastoid angle of the parietal bone, behind the ear, next to philoprogenitiveness and adhesiveness. *Function.* Courage, and the propensity to attack. Quarrelsomeness.

6. **Destructiveness.** Above the ear, corresponding to the squamous plate of the temporal bone, below secretiveness, and next to combativeness. *Function.* Desire to destroy in general. Murder.

7. **Constructiveness.** At that part of the frontal bone, above the spheno-temporal suture next acquisitiveness, about 1½ inch from the eye, and nearly in a line with destructiveness. *Function.* The tendency to construct in general. Mechanical skill.

8. **Acquisitiveness.** At the anterior inferior angle of the parietal bone, between constructiveness and secretiveness. *Function.* Desire to possess in general. Avarice, theft.

9. **Secretiveness.** At the inferior edge of the parietal bones, above destructiveness, or in the middle of the lateral portion of the brain. *Function.* Tendency to conceal. Cunning, deceit.

SENTIMENTS.

10. **Self-esteem.** At the top of the head above the posterior, or sagittal angle of the parietal bones, above concentrativeness. *Function.* Self-love in general. Dignity, conceit, pride, selfishness.

11. **Love of Approbation.** On each side of self-esteem, about half an inch from the lambdoidal suture. *Function.* Love of other's esteem, and the expression of it in praise, bashfulness, fame.

12. **Cautiousness.** Near the middle of the parietal bone, where ossification generally begins, love of approbation and secretiveness. *Function.* The emotion of fear in general. Care, deliberation, doubt, panic.

13. **Benevolence.** At the upper part of the frontal bone, in the coronal aspect, before the fontanel, above the brow, next veneration. *Function.* Desire of the happiness of others. Philanthropy, hospitality.

14. **Veneration.** At the middle of the coronal aspect, at the bregma, or fontanel, between benevolence and firmness. *Function.* The sentiments of respect, reverence, and adoration. Religion, idolatry, toryism.

15. **Hope.** On each side of veneration, under part of the frontal, and part of the parietal bones. *Function.* Tendency to believe in the possibility of obtaining our desires. Belief, credulity.

16. **Ideality.** Along the lower edge of the temporal ridge of the frontal bone, above acquisitiveness. *Function.* The feeling of exquisiteness and perfectibility. Sensations of sublime and beautiful. Fine Arts. Enthusiasm.

17. **Wonder.** Above Ideality. *Function.* Sensations of novelty, surprise, astonishment. News. mystery, supernatural agency.

18. **Conscientiousness.** On the posterior and lateral parts of the coronal surface of the brain, above Cautiousness, behind Hope. *Function.* Feelings of right and wrong. Justice. Duty.

19. **Firmness.** At the posterior part of the coronal surface of the head, close upon the middle line, between self-esteem and veneration. *Function.* To produce determination, constancy, perseverance, and fortitude. Decision of character, obstinacy, stubbornness, infatuation.

INTELLECT.

20. **Individuality.** In the middle of the lower part of the forehead, or brow, below comparison, Nos. 1 and 2. *Function.* The desire and ability to know facts and things. Philosophy, science, metaphor.

21. **Form.** Between the eyes; the degrees of this organ correspond to the greater or less development of brain, situate on the mesial, or inner side of the orbitary plates of the frontal bone, on each side of the *crista galli*. *Function.* To judge of form, to distinguish faces. Imitative arts.

22. **Size.** Above the eyes: below locality. *Function.* Facility in estimating size. Perspective.

23. **Weight or Resistance.** Above the eyes; next size. *Function.* To judge of the weight, resistance, or momentum of bodies. Laws of mechanics.

24. **Colouring.** Above the eyes: next weight. *Function.* To perceive colours. Painting, dyeing, &c.

25. **Locality.** Above size and weight. *Function.* Local memory. Desire for travelling. Topography, geography, astronomy, landscape, painting, &c.

26. **Order.** Above the eyes; between colouring and number. *Function.* Love of order and arrangement. Desire to see every thing in its place.

27. **Time.** Above colouring and locality. *Function.* Recollection of dates, judging of time and of intervals in general. Chronology, association.

28. **Number.** The arch of the eye-brow is either much pressed downward, or there is an elevation at the external angle of the orbit next Order. *Function.* The conception of number and its relations. Arithmetic, algebra, logarithms.

29. **Tune.** In the lateral part of the forehead, between constructiveness and wit, *Function.* The perception of melody. Taste for music.

30. **Language.** In the eyes. *Function.* Faculty of acquiring the knowledge and the use of language. Style, volubility, verbal memory.

31. **Comparison.** In the upper and middle portion of the frontal bone, between benevolence and individuality. *Function.* Power of perceiving resemblances, similitudes, analogies, and coincidences. Reasoning by comparison, proverbs, parables,

32. **Causality.** In the upper part of the frontal bone, on each side of comparison. *Function.* Desire to discover causes and their connection with effects. Deep penetration, genius for metaphysics, political economy, and similar sciences. Speculation, abstraction.

33. **Wit.** In the anterior-superior-lateral parts of the forehead, between casualty and Tune. *Function.* Disposition to view objects in a ludicrous light. Humour, joke satire, epigrams.

34. **Imitation.** In the superior-anterior portion of the head, on the two sides of benevolence, rising up in the form of a segment of a circle. *Function.* The power of imitation in general. Found in artists, players, painters, sculptors, engravers, &c.

We cannot quit this subject without venturing a prediction, which we firmly believe a few years will verify. viz. that phrenology, when better understood, and more amply confirmed by experience, will be found to diffuse a flood of light over many parts of the Old Testament Scriptures, which at present appear obscure and uninteresting.

PHYLACTERY, in antiquity, a charm or amulet, which being worn, was supposed to preserve people from certain evils, diseases, and dangers. The Jews were remarkable for wearing phylacteries of parchment, in the form of slips or rolls, wherein were written certain passages of the law: these they wore upon their foreheads, and upon the wrists of their left arms. See Matthew, chap. xxiii.

PHYSETER, **Cachalot**, a genus of fishes of the order cete. The generic character is, teeth visible in the lower jaw only; spiracle on the head or snout. 1. Physeter macrocephalus, blunt-headed cachalot. This whale, which is one of the largest species, is scarcely inferior in size to the great mysticete, often measuring sixty feet or more in length. The head is of enormous size, constituting more than a third of the whole animal; the mouth wide; the upper lip rounded, thick or high, and much broader than the lower; which is of a somewhat sharpish form, fitting in a manner, into a longitudinal bed or groove in the upper. The teeth, at least the visible ones, as mentioned in the generic character, are situated only in the lower jaw; and when the mouth is closed, are received into so many corresponding holes or cavities in the upper: they are pretty numerous, rather blunt, and of a somewhat conic form, with a very slight bend or inclination inwards. There are also, according to Fabricius, small curved, flattish, concave, and sharp-pointed teeth, lying almost horizontally along the upper jaw; though, from their peculiar situation and size, they are not visible like those of the lower; being imbedded in the fleshy interstices of the holes which receive the lower teeth, and presenting only their internal concave surfaces to meet the latter when the mouth is closed. The front of the head is very abrupt, descending perpendicularly downwards; and on its top, which has been improperly termed the neck by some authors, is an elevation or angular prominence containing the spiracle, which appears externally simple, but is double within. The head is distinguished or separated from the body by a transverse furrow or wrinkle. The eyes are small and black: and the ears or auditory passages extremely small. About the middle of the back is a kind of spurious fin, or dorsal tubercle, of a callous nature, not moveable, and somewhat abrupt or cut off behind. The tongue is of the shape of the lower jaw, clay-coloured externally, and of a dull red within. out is but small in proportion to the animal. The body is cylindrical beyond the pectoral fins, growing narrower towards the tail. The colour of the whole animal is black, but when advanced in age grows whitish beneath. It swims swiftly, and is said to be a violent enemy to the squalus carcharias, or white shark, which is sometimes driven ashore in its endeavours to escape, and according to Fabricius, will not venture to approach its enemy, even when dead, though fond of preying on other dead whales.

It is in a vast cavity within the upper part of the head of this whale, that the substance called spermaceti is found, which while fresh and in its natural receptacle, is nearly fluid; but when exposed to the air, concretes into opake masses: this substance being so universally known, it becomes unnecessary to describe it further.

A more curious and valuable production, the origin of which had long eluded the investigation of naturalists, is obtained from this animal, viz. the celebrated perfume called ambergris, which is found in large masses in the intestines, being in reality no other than the fæces.

Physician, one who professes medicine, or the art of healing diseases. See Medicine.

PHYSICS, a term made use of by Dr. Keil and others, for natural philosophy, explains the doctrine of natural bodies, their phenomena, causes, and effects, with the various affections, motions, and operations. Experimental physics inquire into the reasons and nature of things by experiments, as in hydrostatics, pneumatics, optics, &c. but more particularly in chemistry, in which more has been done the last thirty years than could possibly have been conceived by the imagination. Mechanical physics explain the appearances of nature from the matter, motion, structure, and figures of bodies, and their parts, according to the settled laws of nature.

PHYSIOGNOMY, is a term applied to the peculiar combination of features, which designates the feelings and dispositions of the mind. That every individual of the human race possesses a set of distinctive marks, in the form of the head and the outlines of the countenance, is visible to the most inattentive observer; and it is well known, that those marks insensibly lead us to form conclusions as to the nature and inclinations of persons to whom we are introduced for the first time, which may sometimes be correct, but are frequently erroneous.

This subject, which, for a considerable time, has occupied the attention of philosophers, has now assumed a new name, and the reader will find a short notice of it under the term phrenology.

PHYSIOLOGY, is the science which treats of the powers that actuate the component parts of living animal bodies, and of the functions which those bodies execute.

This science embraces a most extensive field of investigation, indeed the most extensive of any to which the human powers are at all adequate; on this account we would not attempt even an outline of it, but refer the reader to those works in which it is to be found, treated of at large, amongst which the productions of Haller, Richerand, Blumenbach and Lawrence, hold a conspicuous place.

PHYTOLOGY, a discourse concerning the kinds and virtues of plants.

PHYTOTAMA, a genus of birds of the

order passeres; the generic character is, bill conic straight, serrate; nostrils oval; tongue short, obtuse; feet four-toed. There is only a single species viz. P. rara, that inhabits Chili, nearly equal in size to the quail;

PIA MATER. See ANATOMY.

PICA. See MUS.

PICÆ, the second order of birds, according to the Linnæan system. They are distinguished by a bill sharp-edged, convex above; legs short, strong, feet formed for walking, perching, or climbing; body toughish, impure; food various, filthy substances; nest in trees; the male feeds the female while she is sitting. They live in pairs. Of this order there are twenty-six genera.

PICQUET, a celebrated game at cards played between two persons, with only thirty-two cards; all the twos, threes, fours, fives, and sixes, being set aside.

PICUS, the *woodpecker*, in ornithology, a genus belonging to the order of picæ. The beak is straight, and consists of many sides, and like a wedge at the point: the nostrils are covered with bristly feathers; the tongue is round like a worm, very long and sharp at the point, which is beset with bristles bent backwards.

The grand characteristic of these birds is the tongue, the muscles necessary to the motions of which are singular and worthy of notice, affording the animal means of darting it forwards the whole length, or drawing it within the mouth at will. Latham enumerates no less than 50 different species of woodpeckers, besides varieties of some of them which amount to nine more.

PIEPOUDRE, *Court of*, the lowest, and at the same time the most expeditious, court of justice known to the law of England. It is a court of record, incident to every fair and market; and of which the steward of him who holds the toll of the market is the judge. It was instituted to administer justice for all commercial injuries done in that very fair or market, and not in any preceding one; so that the injury must be done, complained of, heard and determined, within the compass of one and the same day, unless the fair continues longer.

PIGEONS. Every person who shall shoot at, kill, or destroy a pigeon, may be committed to the common jail for three months, by two justices of the peace, or pay 20*s* to the poor.

PIKE, an offensive weapon, consisting of a shaft of wood, twelve or fourteen feet long, headed with a flat-pointed steel, called the spear.

PILASTAS. See ARCHITECTURE.

PILE, in artillery, denotes a collection or heap of shot or shells, piled up by horizontal courses into either a pyramidal or else a wedgelike form: the base being an equilateral triangle, a square, or a rectangle. In the triangle and square, the pile terminates in a single ball or point, and forms a pyramid.

PILOT, a person employed to conduct ships over bars and sands, or through intricate channels, into a road or harbour.

PIN, in commerce, a little necessary instrument made of brass wire, chiefly used by women in adjusting their dress.

PINCHBECK, an alloy containing three parts of zinc, and four of copper: it assumes the colour of gold, but it is not so malleable as brass. See ZINC.

PINE. See PINUS.

PINE-APPLE. See BROMELIA.

PINGUIN, or PENGUIN. See APTENODYTES.

PINION, in mechanics, an arbor, or spindle, in the body whereof are several notches, which catch the teeth of a wheel that serves to turn it round; or it is a lesser wheel which plays in the teeth of a larger.

PINITE, a mineral that has received its name from Pini in Saxony, where it has been found in granite. Its colour is reddish brown or black; always in crystals, either rhomboidal prisms, or six sided prisms; sometimes entire; sometimes having their alternate lateral edges truncated: sometimes whole; surface smooth and brilliant; fracture uneven, passing to conchoidal; specific gravity 2.9.

PINK, a vessel used at sea, masted and rigged like other ships, only that this is built with a round stern: the bends and ribs compassing so as that her sides bulge out very much.

PINK. See *Dianthus*.

PINNA, in zoology, a genus belonging to the order of vermes testaceæ. The animal is a slug. The shell is bivalve, fragile, and furnished with a beard, gapes at one end; the valves hinge without a tooth.

PINNACE, a small vessel used at sea with a square stern, having sails and oars, and carrying three masts, chiefly used as a scout for intelligence, and for landing of men, &c. One of the boats belonging to a great man of war, serving to carry the officers to and from the shore, is also called the pinnace.

PINUS, the *pine tree*, a genus of the monadelphia order, in the monœcia class of plants. The male calyx is four-leaved; no corolla; stamina very many, with naked anthers: fem. cal. strobiles, with a two-flowered scale; corolla none; pistil one; nut with a membraneous wing. There are 21 species of this genus.

PIONEERS, in the art of war, are such as are commanded in from the country, to march with an army for mending the ways, for working on entrenchments and fortifications, and for making mines and approaches.

PIP, or *Pep*, pepia, a disease among poultry, consisting of a white thin skin, or film, that grows under the tip of the tongue, and hinders their feeding.

PIPE, in building &c. a canal or conduit, for the conveyance of water and other fluids. Pipes for water, water-engines, &c. are usually of lead, iron, earth, or wood: the latter are commonly made of oak or elder. Those of iron are cast in forges; their usual length is about two feet and a half; several of these are commonly fastened together by means of four screws at each end, with leather or old hat between them, to stop the water. Those of earth are made by the potters; these are fitted into one another, one end being always made wider than the other. To join them the closer, and prevent their breaking, they are covered with tow and pitch: their length is usually about that of the iron pipes. The wooden pipes are trees bored with large iron augurs, of different sizes, beginning with a less, and then proceeding with a larger successively; the first being pointed, the rest formed like spoons, increasing in diameter. from one to six inches or more they are fitted into the extremity of each other, and sold by the foot.

Pipes, *tobacco,* are made of various fashions; long, short, plain, worked, white, varnished, unvarnished, and of various colours, &c. The Turks use pipes three or four feet long, made of rushes, or of wood bored, at the end whereof they fix a kind of pot of baked earth, which serves as a bowl, and which they take off after smoking.

Pipe also denotes a vessel or measure for wine, containing 126 gallons.

PIPER, pepper; a genus of the trigynia order, in the diandria class of plants. There is no calyx or corolla; the berry is one-seeded. There are sixty species, of which the most remarkable is the siriboa, with oval, heart-shaped, nerved leaves, and reflexed spikes. This is the plant which produces the pepper so much used in food. It is a shrub whose root is small, fibrous, and flexible; it rises into a stem, which requires a tree or prop to support it.

PIRATE, one who maintains himself by pillage and robbing at sea. By statute 28, Henry VIII, c. 15, all felonies committed upon the sea, or any place where the Admiral has jurisdiction, shall be tried wherever the king shall appoint by his special commission, as if the offence had been at common law.

And by statute 6, George I. if any subjects or denizens of this kingdom, commits any hostility against others of the king's subjects upon the sea, under colour of any commission from any prince or other authority, he shall be deemed a pirate, and suffer accordingly.

By statute 18, George II. c. 30, persons committing hostilities, or aiding enemies at sea, may be tried as pirates. Piracies at sea are excepted out of the general pardon by 20 George II. c. 52.

PISCES, in natural history, is the fourth class in the Linnæan system, consisting of five orders, viz.

Abdominales	Jugulares
Apodes	Thoracici
Cartilaginii	

The class is described as having incumbent jaws; eggs without white; organs of sense; for covering, imbricate scales; fins for supporters: they swim in water.

Of the various functions of fishes, the most important is that of respiration; this is performed by means of gills, which supply the place of lungs. This process, in fishes, as breathing in the human subject, is carried on during sleep, and is repeated about twenty-five times in a minute; and the necessity of it is evinced from the circumstance of fish being certainly killed in water, from which air is taken away by means of the air-pump, or excluded by very severe frost. Should the free play of the gills be even suspended, or their covers kept from moving, by a string tied round them, the fish would fall into convulsions, and die in a few minutes. It is said, likewise, that though the bronchial apparatus be comprised in a small compass, its surface when fully extended would occupy many square feet; a fact, that may convince the most sceptical, of the numberl[illegible] convolutions and ramifications in which the included water is elaborated and attenuated, in the course of giving out its air in the respiratory process.

Fishes have the organs of sense, some of them probably in a very high degree, and others imperfectly; of the latter kind are the senses of touch and of taste: but the sense of hearing has now been completely ascertained, which was long doubted, and by some physiologists denied; the organ is contained in the cavity of the head.

The organ of smelling is large, and the animals have a power of contracting and dilating the entry to it as they have occasion. It seems to be mostly by their acute smell that they discover their food, for their tongue seems not to have been designed for a very nice sensation, being of a pretty firm cartilaginous substance; and common experience evinces that their sight is not of so much use to them as their smell in searching for their nourishment.

The optic nerves in fishes are not confounded with one another in their middle progress between their origin and the orbit, but the one passes over the other without any communication; so that the nerve which comes from the left side of the brain goes distinctly to the right eye, and *vice versa.*

We must here notice the motion of fishes, for the celerity of which their shape is admirably adapted: hence, vessels designed to be navigated in water are made to imitate, in some degree or other, the shape of fish; but the rapidity of a ship in sailing before the wind is not to be compared to the velocity of a fish. The largest fishes are known to overtake a ship in full sail with the greatest ease, to play round it without effort, and to surpass it at pleasure. Every part of the body seems formed for dispatch: the fins, the tail, and the motion of the whole back-bone assist in the business; and it is to that flexibility of body which mocks the efforts of art, that fishes owe the great velocity of their motions. The chief instruments in a fish's motion are its fins, air-bladder, and tail; with two pair, and three single fins, it will migrate a thousand leagues in a season, and without indicating any visible symptoms of languor or fatigue. The fins serve not only to assist the animal in progression, but in rising and sinking, in turning, and even in leaping out of the water.

By means of the air bladder, fishes can increase or diminish the specific gravity of their body. When they contract it, and press out the air, the bulk of the body is diminished, and the fish sinks as far as it pleases; on relaxing the operation, the bladder acquires its natural size, the body becomes specifically lighter, and the fish is enabled to swim near the surface. The tail, in the last place, may be regarded as the rudder, directing the motions of the fish, to which the fins are only subservient.

With respect to the nourishment of fishes: they are mostly carnivorous, though they seize upon almost any thing that falls in their way, and not uncommonly devour their own offspring: they seem, indeed, to manifest a particular predilection for whatever they can swallow possessed of life. They often meet with each other in fierce opposition, and the victor, without scruple, devours his antagonist. Fishes can, however, notwithstanding their natural voracity, live long, apparently, without food; but they, perhaps, in vases, and other ornamental vessels, feed on insects too small for the human eye to see; or, it has been thought, they

may have the power of chemically decomposing water.

In most, if not in all fishes, there is a difference in sex, though Bloch and others make mention of individuals, which seemed to unite the two sexes, and to be real hermaphrodites. The number of males, it has been remarked is about double that of females; and were it not for this wise provision of nature, a large proportion of the extruded eggs would remain unfecundated. A few species, indeed, as the eel, blenny, &c. are viviparous; but by far the greater number are produced from eggs. These last compose the roe, ovaries of the females, which lie along the abdomen. The milt of the males is disposed along the backbone, in one or two bags, and consists of a whitish glandular substance, which secretes the spermatic fluid.

Fishes have different seasons for depositing their spawn. Some, which live in the depths of the ocean, choose the winter months; but, in general, those with which we are acquainted choose the hottest months in summer, and prefer such water as is somewhat tepified by the beams of the sun. They then leave the deepest parts of the ocean, which are the coldest, and shoal round the coasts, or swim up the fresh-water rivers, which are warm as they are comparatively shallow, depositing their eggs where the sun's influence can most easily reach them, and seeming to take no farther charge of their future progeny. Of the eggs thus deposited, scarcely one in a hundred brings forth an animal, as they are devoured by all the lesser fry which frequent the shores, by aquatic birds near the margin, and by the larger fish in deep water. Still, however, the sea is amply supplied with inhabitants: and notwithstanding their own rapacity, and that of various tribes of fowls, the numbers that escape are sufficient to relieve the wants of a considerable portion of mankind. Indeed, when we consider the fecundity of a single fish, the amount will seem astonishing. If we should be told, for example, that a single being could in one season, produce as many of its kind as there are inhabitants in England, it would strike us with surprise: yet the cod annually spawns, according to Lewenhoeck, above nine million of eggs contained in a single roe. The flounder is commonly known to produce above one million; and the mackerel above five hundred thousand; a herring of a moderate size will yield at least ten thousand: a carp, of fourteen inches in length, contained, according to Petit, two hundred and sixty two thousand two hundred and twenty-four; and another, sixteen inches long, contained three hundred and forty-two thousand one hundred and forty-four; a perch deposited three hundred and eighty thousand six hundred and forty; and a female sturgeon, seven million six hundred and fifty-three thousand two hundred. The viviparous species are by no means so fruitful; yet the blenny brings forth two or three hundred at a time, all alive and playing round the parent together.

PISCES, in astronomy, the twelfth sign or constellation of the zodiac. The stars in Pisces, in Ptolemy's catalogue, are 38; in Tycho's, 33; and in the Britannic catalogue, 109.

PISCIS VOLANS, a small constellation of the southern hemisphere, unknown to the ancients, and invisible to us in these northern regions.

PISOLIT, a mineral found at Carlsbad, in Bohemia. It has the form of round masses composed of concentric layers, and containing a grain of sand in their centre. Colour white, often greyish, reddish, or yellowish.

PISONIA, a genus of the polygamia diœcia class of plants, the corolla whereof is of an infundibuliform shape; the tube is short; the limb is semiquinquefid, acute, and patulous; the fruit is an oval quinquangular capsule, formed of five valves, and containing only one cell; the seed is single, smooth, and oval-oblong. There are five species, trees of the West Indies.

PISTACHIA, *turpentine-tree, pistachia nut, mastich-tree;* a genus of the pentandria order, in the diœcia class of plants. There are six species.

PISTIA, a genus of the monadelphia octandria class and order. There is no calyx; the corolla is one-petalled, tongue-shaped, entire; anthers six or eight; style one; capsule one-celled. There is one species, an aquatic of Senegal.

PISTIL. See *Botany.*

PISTON. See *Pump.*

PISUM, *Pea;* a genus of the decandria order, in the diadelphia class of plants. The style is triangular, above one celled, pubescent; calyx has the two upper segments shorter. The species are, 1. The sativum, or garden-pea. 2. The maritimum, or sea-pea, with footstalks which are plain on their upper side, an angular stalk, arrow-pointed stipulæ, and footstalks bearing many flowers. 3. The ochrus, with membranaceous running footstalks, having two leaves and one flower upon a footstalk.

PITCH, a tenacious oily substance, drawn chiefly from pines and firs, and used in shipping, medicine, and various other arts; or it is more properly tar, inspissated by boiling it over a slow fire. See BITUMEN.

PITCH, *mineral*, has a strong resemblance to common pitch. Colour black, dark brown, or reddish. Specific gravity from 1.45 to 2. Does not stain the fingers. On a white iron it flames with a strong smell, and leaves a quantity of grey ashes. See BITUMEN.

PITCHSTONE. This stone, which occurs in different parts of Germany, France, and other countries, has obtained its name from some resemblance which it has been supposed to have to pitch. It is most usually in amorphous pieces of different sizes.

PITH, in vegetation, the soft spongy substance contained in the central parts of plants and trees.

PLAGUE. Any infectious distemper in foreign countries may be declared the plague, by the king's proclamation. And there are several very salutary regulations by our statute law for the performance of quarantine in order to prevent the extending of infection.

PLAIN *table*, in surveying, a very simple instrument, whereby the draught of a field is taken on the spot, without any future protraction.

PLAN, in general, denotes the representation of something drawn on a plane; such are maps, charts, ichnographies, &c. See MAP, CHART, &c.

The term plan, however, is particularly used

for a draught of a building, such as it appears or is intended to appear, on the ground; shewing the extent, division, and distribution of its area, or ground-plot into apartments, rooms, passages, &c.

PLANE. See GEOMETRY.

PLANE, in joinery, an edged tool, or instrument for paring and shaving of wood smooth. It consists of a piece of wood, very smooth at bottom, as a stock or shaft; in the middle of which is an aperture, through which a steel-edge, or chisel, placed obliquely, passes, which being very sharp, takes off the inequalities of the wood it is slid along. A great improvement in the construction of this instrument has just been made by an ingenious carpenter named Gladwin: it answers all the purposes of the jack-plane, the pannel-plane, the smoothing-plane, and the moulding-plane. For this invention he has been rewarded by the Society of Arts.

PLANET. See ASTRONOMY.

PLANETARIUM, an astronomical machine, made to represent the motions of the planets, and their satellites, as they really are in nature.

PLANISPHERE, signifies a projection of the sphere, and its various circles on a plane; in which sense maps, wherein are exhibited the meridians, and other circles of the sphere, are planispheres.

PLANISPHERE, is more particularly used for an astronomical instrument used in observing the motions of the heavenly bodies. It consists of a projection of the celestial sphere upon a plane, representing the stars, constellations, &c. in their proper order; some being projected on the meridian, and others on the equator.

PLANTING. See AGRICULTURE.

PLASHING *of quickset hedges*, an operation very necessary to promote the growth and continuance of old hedges.

It is performed in this manner: The old stubs must be cut off, &c. within two or three inches of the ground, and the best and longest of the middle-sized shoots must be left to lay down. Some of the strongest of these must also be left to answer the purpose of stakes. These are to be cut off to the height at which the hedge is intended to be left; and they are to stand at ten feet distance one from another: when there are not proper shoots for these at the due distances, their places must be supplied with common stakes of dead wood. The hedge is to be first thinned, by cutting away all those shoots which are intended to be used either as stakes or the other work of the plashing: the ditch is to be cleaned out with the spade; and it must be now dug as at first, with sloping sides each way; and when there is any cavity on the bank on which the hedge grows, or the earth has been washed away from the roots of the shrubs, it is to be made good by facing it, as they express it, with the mould dug from the upper part of the ditch: all the rest of the earth dug out of the ditch is to be laid upon the top of the bank, and the owner should look carefully into it that this is done; for the workmen, to spare themselves trouble, are apt to throw as much as they can upon the face of the bank; which being by this means overloaded, is soon washed off into the ditch again, and a very great part of the work undone; whereas, what is laid on the top of the bank always remains there, and makes a good fence of an indifferent hedge.

PLASTER, in pharmacy, is defined to be an external application, of a harder consistence than our ointments: these are to be spread according to the different circumstances of the wound, place, or patient, either upon linen or leather.

PLASTER OF PARIS. See GYPSUM.

PLATALEA, the *spoonbill*, in ornithology, a genus belonging to the order of grallæ. The beak is plain, and dilates towards the point into an orbicular form; the feet have three toes, and are half-palmated. There are three species, distinguished by their colour: and of these species there are three varieties; two of which are called the white species, and one of the roſeate.

PLATANUS, the *plane-tree*, a genus of the polyandra order, in the monœcia class of plants. The male calyx is an ament, globular; corolla scarcely apparent; anthers growing round the filament. Female calyx ament, globular; corolla many petalled; stigma removed; seeds roundish, marcomate with the style, pappose at the base.

PLATFORM, in the military art, an elevation of earth, on which canon is placed to fire on the enemy; such are the mounts in the middle of curtains. On the ramparts there is always a platform, where the cannon are mounted. It is made by the heaping up of earth on the rampart; or by an arrangement of madriers rising insensibly, for the cannon to roll on, either in a casement or on attack in the outworks. All practitioners are agreed that no shot can be depended on, unless the piece can be placed on a solid platform; for if the platform shakes with the first impulse of the powder, the piece must likewise shake, which will alter its direction, and render the shot uncertain.

PLATINA. See CHEMISTRY.

PLATING, is the art of covering baser metals with a thin plate of silver either for use or for ornament. It is said to have been invented by a spur-maker, not for show but for real utility. Till then the more elegant spurs in common use were made of solid silver; and from the flexibility of that metal, they were liable to be bent into inconvenient forms by the slightest accident. To remedy this defect, a workman at Birmingham contrived to make the branches of a pair of spurs hollow, and to fill that hollow with a slender rod of steel or iron. Finding this a great improvement, and being desirous to add cheapness to utility, he continued to make the hollow larger, and of course the iron thicker and thicker, till at last he discovered the means of coating an iron spur with silver in such a manner as to make it equally elegant with those which were made wholly of that metal. The invention was quickly applied to other purposes; and to numberless utensils which were formerly made of brass or iron are now given the strength of these metals, and the elegance of silver, for a small additional expense.

PLATONIC YEAR, or the GREAT YEAR, is a period of time determined by the revolution of the equinoxes, or the space wherein the stars and constellations return to their former places in respect of the equinoxes. The Pla-

tonic year, according to Tycho Brahe, is 25816: according to Ricciolus 25920; and according to Cassini 24800 years.

PLATOON, in the military art, a small square body of forty or fifty men drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them; or in ambuscades, straits, and defiles, where there is not room for whole battalions or regiments.

PLATYLOBIUM, a genus of the diadelphia decandria class and order. The calyx is bell-shaped, five-cleft; the two upper segments very large; legume pedicelled, compressed, winged at the back. There is one species a shrub of South Wales.

PLATYPUS, a quadruped of the order of bruta. The generic character is, mouth shaped like the bill of a duck; feet webbed.

PLEA, that which either party alleges for himself in court. These are divided into pleas of the crown and common pleas.

Pleas of the crown are all suits in the king's name against offences committed against his crown and dignity, or against his crown and peace. Common pleas are those that are held between common persons.

Common pleas are either dilatory or pleas to the action.

Pleas dilatory are such as tend merely to delay or put off the suit, by questioning the propriety of the remedy rather than by denying the injury.

Pleas to the action are such as dispute the very cause of suit.

PLEADINGS, in general, signify the allegations of parties to suits when they are put into a proper and legal form; and are distinguished in respect to the parties who plead them by the names of bars, replications, rejoinders, sur-rejoinders, rebutters, sur-rebutters, &c.; and though the matter in the declaration of court does not properly come under the name of pleading, yet, being often comprehended in the extended sense of the word, it is generally considered under this head.

PLEIADES, in astronomy, an assemblage of stars in the neck of the constellation Taurus. See ASTRONOMY.

PLENE ADMINISTRAVIT, a plea pleaded by an executor or administrator, where they have administered the deceased's estate faithfully and justly before the action brought against them.

PLENUM, in physics, denotes, according to the Cartesians, that state of things wherein every part of space is supposed to be full of matter; in opposition to a vacuum.

PLENUS *flos*, in botany, *a full flower*; a term expressive of the highest degree of luxuriance in flowers. The petals in full flowers are so multiplied as to exclude all the stamina, and frequently to choak up the female organ, so that such flowers, though delightful to the eye, are vegetable monsters. Flowers with more than one petal are most liable to this; such are the ranunculus, anemony, poppy, myrtle, &c. &c. Flowers with one petal only are but seldom subject to this fulness; these, however, are not totally exempt, as may be seen in the double polyanthus, hyacinth, crocus, &c. In flowers with one petal, the mode of luxuriance, or impletion is by a multiplication of the divisions of the limb or upper part. In flowers with more than one petal by a multiplication of the petals or nectarium.

PLEURISY, in medicine, a violent pain in the side, attended with an acute fever, a cough, and a difficulty of breathing.

PLEURONECTES, *flounder*, a genus of fishes of the order thoracici, of which there are 17 species. The generic character is, eyes both on the same side of the head; body compressed, one side representing the back, and the other the abdomen.

The singular structure of this genus is justly considered as one of the most curious deviations from the general uniformity or regularity observed by nature in the external figure of animals, in which (except in a very few instances) both sides of the body are perfectly similar; but in the genus pleuronectes the animal is so constituted, that one side appears to represent the back, and the opposite side the abdomen. They swim laterally, and the eyes are always placed on one side. It is from this circumstance that the division of the species is conducted, viz. into those which have the eyes dextrous, or towards the right, when the fish is laid with its coloured side upwards with its abdomen towards the spectator; and sinistrous when the eyes are towards the left in the above situation of the fish.

PLOT, in dramatic poetry, is sometimes used for the fable of a tragedy or comedy, but more particularly the knot of intrigue, which makes the embarras of any piece. The unravelling puts an end to the plot.

PLOT, in surveying, the plan or draught of any field, farm, or manor surveyed with an instrument, and laid down in the proper figure and dimensions.

PLOTTING, among surveyors, is the art of laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, &c. and a chain. In surveying with the plain table, the plotting is saved; the several angles and distances being laid down on the spot, as fast as they are taken.

PLOUGH, in agriculture, a machine for turning up the soil, contrived to save the time, labour, and expence, that without this instrument must have been employed in digging land, to prepare it for the sowing of all kinds of grain. See AGRICULTURE.

PLOUGH, among bookbinders, is a machine for cutting the edges of the leaves of books smooth.

PLUM-*tree*. See PRUNUS.

PLUMB-*line*, among artificers, denotes a perpendicular to the horizon; so called as being commonly erected by means of a plummet.

PLUMBERY is the art of casting and working lead, and using it in the various departments of life, as buildings pipes &c.

PLUMMET, plumb-rule, or plumb-line, an instrument used by carpenters, masons, &c. in order to judge whether walls, &c. are upright planes, horizontal, or the like. It is thus called from a piece of lead, fastened to the end of a cord, which usually constitutes this instrument. Sometimes the string descends along a wooden ruler, &c. raised perpendicularly on another, in which case it becomes a level.

PLUMMING, among miners, is the method of using a mine dial, in order to know

the exact place of the work where to sink down an air shaft, or to bring in an adit to the work, or to know which way the load inclines when any flexure happens in it.

PLUS, in algebra, a character marked thus +, used for the sign of addition. See Algebra.

PLUSH, in commerce, &c a kind of stuff leaving a sort of velvet knap, or shag, on one side, composed regularly of a woof of a single woollen thread, and a double warp, the one wool, of two threads twisted, the other goats' or camels' hair; though there are some plushes entirely of worsted, and others composed wholly of hair.

PNEUMATICS. This term is derived from the Greek *πνευμα, a spirit*, and is used to designate that science which treats of the mechanical properties of air, and other compressible fluids.

The air is a fluid in which we live and breathe; it entirely envelopes our globe, and extends to a considerable height around it. Together with the clouds and vapours that float in it, it is called the atmosphere. As it is possessed of gravity in common with all other fluids, it must press upon bodies in proportion to the depth at which they are immersed in it; and it also presses in every direction, in common with all other fluids.

It differs from all other fluids in the four following particulars: 1. It can be compressed into a much less space than it naturally possesses; 2. It cannot be congealed or fixed as other fluids may; 3. It is of a different density in every part upward from the earth's surface; decreasing in its weight, bulk for bulk, the higher it rises; 4. It is of an elastic or springy nature, and the force of its spring is equal to its weight.

When the air is at rest, we can move in it with the utmost facility; nor does it offer to us a sensible resistance, except the motion is quick, or the surface opposed to it considerable; but when that is the case, its resistance is very sensible, as may be easily perceived by the motion of a fan.

When air is in motion, it constitutes wind; which is nothing more than a current or stream of air, varying, in its force, according to the velocity with which it flows.

The invisibility of air, therefore, is only the consequence of its transparency; but it is possessed of all the common properties of matter. When a vessel is empty, in the usual way of speaking, it is, in fact, still filled with air.

But it is possible to empty a vessel even of the air which it contains, by which means we shall be able to discover several properties of this fluid. The instrument, or machine, by which this operation is performed, is called an air-pump. As it is by means of this useful instrument that all the mechanical properties of air are demonstrated, it will be necessary to describe its construction, and the manner of using it, before we proceed to the experiments that are made with it.

Plate XLV, fig. 1, is the air-pump that is now most in use. A A are two brass barrels, each containing a piston, with a valve opening upwards. They are worked by means of the winch B, which has a pinion that fits into the teeth of the racks C C, which are made upon the ends of the pistons, and by this means moves them up and down alternately.

On the square wooden frame D E, there are placed a brass plate G, ground perfectly flat, and also a brass tube, let into the wood, communicating with the two barrels and the cock I, and opening into the centre of the brass plate at *a*. The glass vessel K, to be emptied or exhausted of air, has its rim ground quite flat, and rubbed with a little pomatum, or hogs' lard, to make it fit more closely upon the brass plate of the pump. These vessels are called receivers. Having shut the cock I, the pistons are worked by the winch; and the air being suffered to escape when the piston is forced down, because the valve opens upwards, but prevented from returning into the vessel for the same reason, the receiver is gradually exhausted, and will then be fixed fast upon the pump-plate. By opening the cock I, the air rushes again into the receiver.

Of the Pressure of the Air.

When the surface of a fluid is exposed to the air, it is pressed by the weight of the atmosphere equally on every part, and consequently remains at rest. But if the pressure is removed from any particular part, the fluid must yield in that part, and be forced out of its situation.

Into the receiver A, fig. 2, put a small vessel with quicksilver *z*, or any other fluid, and through the collar of leathers at B, suspend a glass tube *x*, closed, or hermetically sealed, as it is called, over the small vessel. Having exhausted the receiver, let down the tube into the quicksilver, which will not rise into the tube as long as the receiver continues empty. But re-admit the air, and the quicksilver will immediately ascend. The reason of this is, that upon exhausting the receiver, the tube is likewise emptied of air; and therefore, when it is immersed in the quicksilver, and the air re-admitted into the receiver, all the surface of the quicksilver is pressed upon by the air, except that portion which lies above the orifice of the tube; consequently, it must rise in the tube, and continue so to do, until the weight of the elevated quicksilver presses as forcibly on that portion which lies beneath the tube, as the weight of the air does on every other equal portion without the tube.

A square column of quicksilver twenty-nine and a half inches high, and an inch thick, weighs just fifteen pounds, consequently, the air presses with a weight equal to fifteen pounds upon every square inch of the earth's surface: and 144 times as much, or 2160 pounds, upon every square foot.

The pressure of the air is beautifully illustrated by what are called the Magdiburgh hemispheres. These are represented by fig. 3, and consist of two hollow hemispheres of brass, which are made to fit upon each other by a ground joint rendered air-tight by a little pomatum. Having screwed off the handle at C, put both the hemispheres together, and screw them into the pump-plate, and turn the cock E, so that the pipe may be open all the way into the cavity of the hemispheres; then exhaust the air out of them, and turn the cock; unscrew the hemispheres from the pump, and having put on the handle C, let two strong

men try to pull the hemispheres asunder by the rings, which they will find hard to do; for if the diameter of the hemispheres is four inches, they will be pressed together by the external air with a force equal to 190 pounds.

Screw the end A of the brass pipe AB, fig. 4, into the pump-plate, and turn the cock *e* until the pipe is open; then put a wet leather on the plate *ca*, fixed on the pipe, and cover it with the tall receiver GH, which is close at top; then exhaust the air out of the receiver, and turn the cock *e* to keep it out; which done, unscrew the pipe from the pump, and set its end A into a bason of water, and turn the cock *e* to open the pipe; on which, as there is no air in the receiver, the pressure of the atmosphere on the water in the bason will drive the water forcibly through the pipe, and make it play up in a jet to the top of the receiver.

Of the Elasticity of the Air.

To shew the elasticity or spring of the air, tie up a very small quantity of air in a bladder, and put it under the receiver; then exhaust the air out of the receiver, and the air which is confined in the bladder (having nothing to act against it) will expand by the force of its spring, so as to fill the bladder completely. But upon letting the air into the receiver again, it will overpower that in the bladder, and press its sides close together.

If the bladder so tied up is put into a wooden box, and has twenty or thirty pounds weight of lead placed upon it, and the box is covered with a close receiver; upon exhausting the air out of the receiver, that which is confined in the bladder will expand itself so as to raise up all the lead by the force of its spring.

A very pleasing variety of this experiment is exhibited by lecturers with what is called the condensed air-fountain. Take a strong copper vessel, fig. 5, having a tube that screws into the neck of it so as to be air tight, and long enough to reach nearly to the bottom. Having poured a quantity of water into the vessel, so as to fill it about three parts full, and screwed in the tube, adapt to it a condensing syringe, and condense the air in the vessel; shut the stop-cock, and unscrew the syringe; then, on opening the stop-cock, the air acting upon the water in the vessel, will force it out into a jet of very great height. A number of different kinds of jets may be screwed on the tube, such as stars, wheels, &c. forming a very pleasing appearance.

But the most striking pneumatic experiment for shewing the elasticity of compressed air, is the air-gun. By means of this instrument, bullets may be propelled with a force nearly equal to that of gun-powder.

Fig. 6 represents the condenser for forcing the air into the ball. At the end *a* of this instrument is a male screw, on which the hollow ball *b* is screwed, in order to be filled with condensed air. In the inside of this ball is a valve, to hinder the air after it is injected from making its escape, until it is forced open by a pin, against which the hammer of the lock strikes; which then lets out as much air as will drive a ball with considerable force to a great distance.

When you condense the air in the ball, place your feet on the iron cross *hh*, to which the piston-rod *d* is fixed; then lift up the barrel *ea*, by the handles *ii*, until the end of the piston is brought between *e* and *c*: the barrel *ac* will then be filled with air through the whole *e*. Then thrust down the barrel *ac* by the handles *ii*, until the piston *e* joins with the neck of the iron ball at *a*: the air, being thus condensed between *e* and *a*, will force open the valve in the ball; and when the handles *ii* are lifted up again, the valve will close, and keep in the air; so by rapidly continuing the stroke up and down, the ball will presently be filled; after which, unscrew the ball off the condenser, and screw it upon another male screw, which is connected with the barrel, and goes through the stock of the gun, as represented fig. 7. Twelve dwts. of air have been injected into a ball of 3.75 inches diameter, which has discharged 15 bullets with considerable force.

It may be expected that we should here give some account of the old magazine air-gun, but we deem that altogether unnecessary, as the modern make of the instrument is far superior, and universally adopted. And, indeed, all the advantages of that clumsy article are combined with the lightest form in which the air-gun is at present made.

Before quitting this article we would just notice, that, although we have given a drawing of the common table pump, it is an article of which we by no means approve, if the experiments are such as require great nicety and quickness of exhaustion.

Cuthbertson's double barrelled pump, which stands table height, is at once the most elegant and powerful instrument that can be used for pneumatical purposes.

In many pneumatic experiments it is required to effect strong condensations of air, and sometimes of gases. For this purpose an instrument, called a condenser, represented at fig. 8, is used. It consists of a brass barrel containing a piston, which has a valve opening downwards; so that as the piston is raised, the air passes through the valve; but as the piston is pushed down, the air cannot return, and is therefore forced through a valve at the bottom of the barrel, that allows it to pass through into the receiver B, but prevents it from returning. Thus, at every stroke of the piston, more air is thrown into the receiver, which is of very thick and strong glass. The receiver is held down upon the plate C by the cross piece D, and the screws EF. The air is let out of the receiver by the cock G, which communicates with it.

POCKET, in the woollen trade, a word used to denote a larger sort of bag, in which wool is packed up to be sent from one part of the kingdom to another. The pocket contains usually twenty-five hundred weight of wool. The pocket of hops is also a small bag usually containing the best hops.

POETRY, or POESY, is a term derived from the Greek ποιητρια, ποιησις, of ποιεω, *I make*, and is used to designate that particular kind of literary composition which is characterized by metrical harmony. *Dr. Blackwall*, in his "Essay on the Life and Writings of Homer," says, on the subject of poetry, that "it is of a nature so delicate, as not to admit of a direct definition; for if ever the *je ne scais quoi* was rightly applied, it is to the

powers of poetry, and the faculty that produces it. To go about to describe it would be like attempting to define inspiration, or that glow of fancy, or effusion of soul, which a poet feels while in his fit; a sensation so strong, that they express it only by abjurings, exclamations, and rapture." To the same purpose, but in less inflated language, Dr. Blair has observed, that it is not so easy as might at first be imagined to ascertain with minute precision wherein poetry differs from prose. In point of fact, every reflecting reader must be sensible, that as it is difficult to determine the precise line where different shades of colour terminate, or even the boundaries of animal and vegetable nature, so it is a matter of no small nicety to fix the point where composition rises from the scale of prose to that of poetry.

By a small addition to the ideas of Aristotle, poetry may, however, be defined an imitative and creative art, whose energies are exerted by means of words metrically arranged, the end and design of which art is to amuse the fancy, and powerfully to excite the feelings.

The word poet, in its original import, signifies creator. And as names are not unfrequently significant of the nature of the ideas which they represent, the name itself of poetry will direct us to one of its most distinguishing characteristics. It is, indeed, one of the noblest qualities of poetry, that it opens to the mind a new creation.

"The poet's eye, in a fine frenzy rolling,
Doth glance from heaven to earth, from earth to heaven:
And as imagination bodies forth
The form of things unknown, the poet's pen
Turns them to shapes, and gives to airy nothing
A local habitation and a name."

But though melodious and metrical arrangement of words be one of the characteristics, and, as Dr. Blair denominates it, "the exterior distinction" of poetry, it is necessary to observe, that too many writers seem to assign to this characteristic a place of eminence to which it is by no means entitled. In consequence of this error, vast multitudes of compositions are obtruded upon the world under the name of poems, which possess no other merit than that of regularity of versification and smoothness of numbers. Against these wearisome productions, Horace has long ago protested in his memorable declaration, that the quality of mediocrity is denied to poets, and that poetry includes something more in its definition than the measuring of syllables and the tagging of a verse. If the heart does not glow with the flame of genius, the mechanism of art will be of no avail.

He who aspires after the title of poet should never, indeed, forget, that the end of poetry is to amuse the fancy and powerfully to excite the feelings, and that this is effected by impressing the mind with the most vivid pictures. In the course of her operations, poetry hurries us beyond the reach of sober judgment, and captivates by rousing the energy of passion. Here then we see the cause of the power of verse, nor wonder at the efficaciousness which has, more especially in early times, been ascribed to the muses. For how easily are mankind guided by those who possess the art of awakening or of allaying their feelings. Though all unconscious of being under the guidance of another, they turn obedient to the rein. They are roused to insurrection, or moderated to peace, by him who can touch with a skilful hand the master springs that regulate the motion of their minds. "The primary aim of a poet," says Dr. Blair, "is to please and to move; and therefore it is to the imagination and the passions that he speaks. He may, and he ought to have it in his view, to instruct and to reform; but it is indirectly, and by pleasing and moving that he accomplishes this end. His mind is supposed to be animated by some interesting object, which fires his imagination, or engages his passions; and which of course communicates to his style a peculiar elevation, suited to his ideas, very different from that mode of expression which is natural to the mind in its calm ordinary state."

POINT, in geometry, as defined by Euclid, is a quantity which has no parts, or which is indivisible. Points are the ends or extremities of lines. If a point be supposed to be moved any way, it will, by its motion, describe a line.

POINTS, in heraldry, are the several different parts of an escutcheon, denoting the local positions of any figure. See HERALDRY.

POINT is also an iron or steel instrument, used with some variety in several arts. Engravers, etchers, cutters in wood, &c. use points to trace their designs on the copper, wood, stone, &c. See ENGRAVING, &c.

POINT, in the manufactories, is a general term, used for all kinds of laces wrought with the needle; such are the point de Venice, point de France, point de Genoa, &c., which are distinguished by the particular economy and arrangement of their points.

POINT-BLANK, in gunnery, denotes the shot of a gun levelled horizontally.

POISONS. Substances which, when applied to living bodies, derange the vital functions, and produce death, by an action not mechanical. The study of their nature, mode of operation, and antidotes, has been called *toxicology.*

Antidotes for poisons have often proved effectual, but in most cases they completely fail; and on this account, the surgeon, who now applies the most powerful of them, may be considered as trifling with the life of his patient, if he neglect the immediate use of the stomach pump, lately invented by Mr. Jukes, by means of which the contents of the stomach may be instantly withdrawn.

POLARITY, the quality of a thing considered as having poles; but chiefly used in speaking of the magnet. See MAGNETISM.

POLARIZATION OF LIGHT. This new branch of optical science sprung from the ingenuity of Malus. It has been since cultivated by M.M. Arago, Fresnel, and Biot, in France, and by Dr. Brewster, in this country.

An excellent article on the subject has appeared in the supplement to the Encyclopædia Britannica, by M.M. Arago.

If a solar ray fall on the anterior surface of an unsilvered mirror plate, making an angle with it of 35° 25′, the ray will be reflected in a right line, so that the angle of reflection will be equal to the angle of incidence. In any point of its reflected path, receive it on

another plane of similar glass, it will suffer in general a second partial reflection. But this reflection will vanish, or become null, if the second plate of glass form an angle of 35° 25′ with the first reflected ray, and at the same time be turned, so that the second reflection is made in a plane perpendicular to that in which the first reflection takes place. For the sake of illustration: suppose that the plane of incidence of the ray on the first glass coincides with the plane of the meridian, and that the reflected ray is vertical. Then, if we make the second inclined plate revolve, it will turn around the reflected ray, forming always with it the same angle; and the plane in which the second reflection takes place will necessarily be directed towards the different points of the horizon, in different azimuths. This being arranged, the following phenomena will be observed.

When the second plane of reflection is directed in the meridian, and consequently coincides with the first, the intensity of the light reflected by the second glass is at its maximum.

In proportion as the second plane, in its revolution, deviates from its parallelism with the first, the intensity of the reflected light will diminish.

Finally, when the second plane of reflection is placed in the prime vertical, that is, east and west, and consequently perpendicular to the first, the intensity of the reflection of light is absolutely null on the two surfaces of the second glass, and the ray is entirely transmitted.

Preserving the second plate at the same inclination to the horizon, if we continue to make it revolve beyond the quadrant now described, the phenomena will be reproduced in the inverse order; that is, the intensity of the light will increase, precisely as it diminished, and it will become equal, at equal distances from the east and west. Hence, when the second plane of reflection returns once more to the meridian, a second maximum of intensity equal to the first recurs.

From these experiments it appears, that the ray reflected by the first glass, is not reflected by the second, under this incidence, when it is presented to it by its east and west sides; but that it is reflected, at least in part, when it is presented to the glass by any two others of its opposite sides. Now, if we regard the ray as an infinitely rapid succession of a series of luminous particles, the faces of the ray are merely the successive faces of these particles. We must hence conclude, that these particles possess faces endowed with different physical properties, and that in the present circumstance, the first reflection has turned towards the same sides of space similar faces, or faces equally endowed at least with the property under consideration. It is this arrangement of its molecules which Malus named the *polarization* of light, assimilating the effect of the first glass to that of a magnetic bar, which would turn a series of magnetic needles, all in the same direction.

Hitherto we have supposed that the ray, whether incident or reflected, formed with the two mirror plates an angle of 35° 25′; for it is only under this angle that the phenomenon is complete. Without changing the inclination of the ray to the first plate, if we vary ever so little the inclination of the second, the intensity of the reflected light is no longer null in any azimuth, but it becomes the feeblest possible in the prime vertical in which it was formerly null.

Similar phenomena may be produced, by substituting for the mirror glasses polished plates formed for the greater part of transparent bodies. The two planes of reflection must always remain rectangular, but they must be presented to the luminous ray at different angles, according to their nature. Generally, all polished surfaces have the property of thus polarizing, more or less completely, the light which they reflect under certain incidences; but there is for each of them a particular incidence, in which the polarization it impresses is most complete; and for a great many, it amounts to the whole of the reflected light.

When a ray of light has received polarization in a certain direction, by the processes now described, it carries with it this property into space, preserving it without preceptible alteration, when we make it traverse perpendicularly a considerable mass of air, water, or any substance possessed of single refraction. But the substances which exercise double refraction. in general alter the polarization of the ray, and apparently in a sudden manner, and communicate to it a new polarization of the same nature, but in another direction. It is only in certain directions of the principal section, that the ray can escape this disturbing force.

POLE, in astronomy, one of the extremities of the axis, on which the sphere revolves. These two points, each ninety degrees distant from the equinoctial or equator, are by way of eminence called the poles of the world; and the extremities of the axis of the artificial globes, corresponding to these points in the heavens, are termed the poles thereof.

Pole, Perch, or **Rod**, in surveying, is a measure containing sixteen feet and a half.

Pole, or **Polar** *star*, is a star of the second magnitude, the last in the tail of ursa minor. Its longitude Mr. Flamsteed makes 24° 14′ 41″; its latitude, 66° 4′ 11″.

Pole-cat. See Viverra.

POLEMONIUM, *Greek valerian*, or *Jacob's ladder*: a genus of the monogynia order in the pentandria class of plants; and in the natural method ranking under the 29th order, campanaceæ. There are five species, of which the most remarkable is the cæruleum, with an empalement longer than the flower. It grows naturally in some places of England: its beauty, however, has obtained it a place in the gardens.

POLICY of ASSURANCE. The deed or instrument by which a contract of assurance is effected. The premium or consideration paid for the risk or hazard assured against, must be inserted in the policy, and likewise the day, month, and year, on which the policy is executed, and it must be duly stamped.

POLL, a word used in ancient writings for the head: hence to poll is either to vote or to enter down the names of those persons who give in their votes at an election.

Poll-money, a capitation or tax imposed by the authority of parliament on the head or person either of all indifferently, or according to some known mark of distinction.

POLLIA, a genus of the class and order hexandria monogynia. The corolla is infe

rior, six-petalled; berry many-seeded. There is one species, an herbaceous plant of Japan.

POLLICHIA, a genus of the monandria monogynia class and order. The calyx is one-leafed, five-toothed; corolla, five petals; seed solitary; receptacle succulent, aggregate scales. There is one species, of the Cape.

POLLUX, in astronomy, a fixed star of the second magnitude in the constellation Gemini or the Twins. See ASTRONOMY.

POLYADELPHIA (from ϖολυς *many*, and αδελφια, *brotherhood*,) many brotherhoods; the name of the 18th class of Linnæus's sexual system, consisting of plants with hermaphrodite flowers in which several stamina or male organs are united by their filaments into three or more distinct bundles.

POLYANDRIA (from ϖολυς, many, and ανερ, a *man* or *husband*,) many husbands; the name of the 13th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with several stamina that are inserted into the common receptacle of the flower.

POLYGAMIA (πολυς, *many*, and γαμος, *marriage*). This term, expressing an intercommunication of sexes, is applied, by Linnæus, both to plants and flowers. A polygamous plant is that which bears both hermaphrodite flowers and male or female, or both.

POLYGAMY, a plurality of wives or husbands, in the possession of one man or woman, at the same time; which by the laws of England is felony.

POLYGLOTT, among divines and critics, chiefly denotes a bible printed in several languages. In these editions of the holy scriptures, the text in each language is ranged in opposite columns.

POLYGON. See GEOMETRY.

POLYGONAL NUMBERS, are so called because the units whereof they consist may be disposed in such a manner as to represent several regular polygons.

POLYNEMUS, *polyneme*, a genus of fishes of the order abdominales. The generic character, is head repressed, covered with scales; snout very obtuse and prominent; gill, membrane five or seven rayed; separate filaments or setaceous processes near the base of the pectoral fins.

POLYPUS, the popular name for those fresh-water insects, which class under the genus of hydra, of the order of vermes zoophytæ. The name of hydra was given them by Linnæus on account of the property they have of reproducing themselves when cut in pieces, every part soon becoming a perfect animal.

PONTON or PONTOON, in war, denotes a little floating-bridge made of boats and planks. The ponton is a machine consisting of two vessels, at a little distance, joined by beams, with planks laid across for the passage of the cavalry, the cannon, infantry, &c. over a river, or an arm of the sea, &c.

POOR-LAWS, the term is applied to those regulations adopted by the country, for the support of all those who are in such a low and mean condition, that they either are, or may become a burden to the parish.

POOR'S-RATE, an assessment raised throughout England and Wales, for the temporary relief, or permanent maintenance, of all such persons, as from age, infirmity, or poverty; cannot themselves procure the means of subsistence.

POPE, PAPA, FATHER, the sovereign pontiff, or supreme head of the Romish church. The appellation of pope was anciently given to all christian bishops: but about the latter end of the eleventh century it was discontinued.

POPULATION, the state of a country with respect to the number of its inhabitants.

The obvious principle, that population is necessarily limited by the means of subsistence has been stated, and conclusions drawn from it, by many different writers; but it has lately been discussed at great length in an "Essay on the Principle of Population," by Mr. T. R. Malthus, who has endeavoured to prove that population invariably increases where the means of subsistence increase, unless prevented by some very powerful and obvious checks; and that these checks, and the checks which repress the superior power of population, and keep its effects on a level with the means of subsistence, are all resolvable into moral restraint, vice, and misery. Under whatever denomination the causes which adjust population to the circumstances of the country may be classed, it is certain that they exist in every civilized country, and while the nature of men remains the same they must continue to exist, although operating in a greater or less degree according to the progress the country has made in cultivation, commerce, and political power.

POPULUS, the POPLAR, a genus of the octandria order, in the diœcia class of plants; and in the natural method ranking under the 50th order, amentaceæ. The calyx of the amentum is a lacerated, oblong, and squamous leaf; the corolla is turbinated, oblique, and entire. The female has the calyx of the amentum and corolla the same as in the male; the stigma is quadrifid; the capsule bilocular, with many pappous seeds. There are eleven species.

PORCELAIN is the most beautiful and the finest of all earthen wares.

The art of making porcelain is one of those in which Europe has been excelled by oriental nations. The first porcelain that was seen in Europe was brought from Japan and China. The whiteness, transparency, fineness, neatness, elegance, and even the magnificence of this pottery, which soon became the ornament of sumptuous tables, did not fail to excite the admiration and industry of Europeans.

Father Entrecolles, missionary at China, sent home a summary description of the process by which the inhabitants of that country make their porcelain, and also a small quantity of the materials which they employ in its composition. He said, that the Chinese compose their porcelain of two ingredients, one of which is a hard stone or rock, called by them petuntse, which they carefully grind to a very fine powder; and the other, called, by them kaolin, is a white earthy substance which they mix intimately with the ground petuntse.

Reaumur examined both these matters; and having exposed them separately to a violent fire, he discovered that the petuntse had

fused without addition, and that the kaolin had given no sign of fusibility. He afterward mixed these matters, and formed cakes of them, which, by baking, were converted into porcelain similar to that of China.

Reaumur gave the quality of porcelain to glass; that is, he rendered glass of a milky colour, semi-transparent, so hard as to strike fire with steel, infusible, and of a fibrous grain, by means of cementation. The process, which he published, is not difficult. Common glass, such as that of which wine bottles are made, succeeds best. The glass vessel which is to be converted into porcelain, is to be enclosed in a baker's earthen case or seggar. The vessel and case are to be filled with a cement composed of equal parts of sand and powdered gypsum or plaster; and the whole is to be put into a potter's kiln, and to remain there during the baking of common earthenware; after which the glass vessel will be found transformed into such a matter as has been described.

PORCUPINE. See Hystrix.

PORE, in anatomy a little interstice or space between the parts of the skin, serving for perspiration. See Cutis, and Physiology.

Pores, are the small interstices between the particles of matter which compose bodies; and are either empty, or filled with some insensible medium.

Condensation and rarefaction are only performed by closing and opening the pores.

PORPHYRY is a compound rock, having a basis, in which the other contemporaneous constituent parts are imbedded. The base is sometimes clay-stone, sometimes hornstone, sometimes compact felspar; or pitchstone, pearlstone, and obsidian. The imbedded parts are most commonly felspar and quartz, which are usually crystallized more or less perfectly, and hence they appear sometimes granular. According to Werner, there are two distinct porphyry formations; the oldest occurs in gneiss, in beds of great magnitude; and also in mica-slate and clay-slate. Between Blair in Athole and Dalnacardoch, there is a very nple of a bed of porphyry-slate in The second porphyry formation is much more widely extended. It consists principally of clay porphyry, while the former consists chiefly of hornstone porphyry and felspar porphyry.

PORT, a harbour or place of shelter, where ships arrive with their freight, and customs from goods are taken.

Port-holes, in a ship, are the holes in the sides of the vessel, through which are put the muzzles of the great guns. These are shut up in storms to prevent the water from driving through them

PORTCULLIS, in fortification, is an assemblage of several large pieces of wood, joined across one another like a harrow, and each pointed with iron at the bottom. They are sometimes hung over the gateway of old fortified towns, ready to let down in case of surprise, when the gates could not be shut.

PORTER, a kind of malt liquor, which differs from ale and pale beer in its being made with high dried malt.

PORTGREVE, or portgrave, anciently the principal magistrate in ports and other maritime towns. The word is formed from the Saxon "port," and "geref," a governor. It is sometimes also written "portreve." It it said by Camden, that the chief magistrate of London was anciently called portgreve, which was exchanged by Richard I. for two bailiffs; and these again gave place, in the reign of king John, to a mayor, who was an annually elected magistrate.

PORTICO, in architecture, a kind of gallery on the ground, supported by columns, where people walk under covert.

PORTLAND-STONE, is a dull whitish species of stone, much used in buildings; it is composed of a coarse grit, cemented together by an earthy spar: it will not strike fire with steel, but makes a violent effervescence with nitric acid.

PORTRAIT. See Painting.

POSITION, or the *rule of false* Position, otherwise called the *rule of* Falsehood, in arithmetic, is a rule so called, because in calculating on several false numbers taken at random, as if they were the true ones, and from the differences found therein, the number sought is determined. This rule is either single or double. Single position is when there happens in the proposition some partition of numbers into parts proportional, in which case the question may be resolved, at one operation, by this rule. Imagine a number at pleasure, and work therewith according to the tenor of the question, as if it were the true number: and what proportion there is between the false conclusion and the false proportion, such proportion the given number has to the number sought. Therefore the number found by argumentation shall be the first term of the rule of three: the second number supposed, the second term; and the given number, the third. Or the result is to be regulated by this proportion, *viz.* As the total arising from the error to the true total, so is the supposed part to the true one. Example, A, B, and C, designing to buy a quantity of lead to the value of 140*l.* agree that B shall pay as much again as A, and C as much again as B; what then must each pay.

Now suppose A to pay 10*l.* then B must pay 20*l.* and C 40*l.* the total of which is 70*l.* but should be 140*l.* Therefore, if 70*l.* should be 140*l.* what should 10*l.* be?

Answer, 20*l.* for A's share, which doubled makes 40*l.* for B's share, and that again doubled gives 80*l.* for C's share, the total of which is 140*l.* Double position is when there can be no partition in the numbers to make a proportion. In this case, therefore, you must make a supposition twice, proceeding therein according to the tenor of the question. If neither of the supposed numbers solve the proportion, observe the errors, and whether they be greater or less than the supposition requires, and mark the errors accordingly with the sign × and —.

Then multiply contrarywise the one position by the other error, and if the errors be both too great, or both too little, subtract the one product from the other, and divide the difference of the errors. If the errors be unlike, as the one + and the other —, add the products, and divide the sum thereof by the sum of the errors added together: for the proportion of the errors is the same with the proportion of the excesses or defects of the numbers supposed to be the number sought: or the sup-

positions and their errors being placed as before, work by this proportion as a general rule, viz. as the difference of the errors, if alike, or their sum, if unlike, is to the difference of the suppositions, so either error to a fourth number, which accordingly, added to or subtracted from the supposition against it, will answer the question.

POSSESSION, is two-fold, actual and in law. Actual possession is when a man actually enters into lands and tenements to him descended. Possession in law, is when the lands or tenements are descended to a man, and he has not as yet actually entered into them.

POST, a military station. Thus the detachments established in front of. the army are termed out-posts; the stations on the wings of the army are said to be the posts of honour, as being the most conspicuous and most exposed. But in the operations of a campaign, a post properly signifies any spot of ground capable of lodging soldiers, or any situation, whether fortified or not, where a body of men may make a stand, and engage the enemy to advantage. The great advantages of good posts, in carrying on war, as well as the mode of securing them, are only learned by experience.

Post, a conveyance for letters or dispatches.

The present establishment of the general post-office of Great Britain, consists of a post-master-general, to the duties of which station there have, for many years past been two persons appointed, under the title of joint post-masters-general; a secretary; upwards of 150 assistants and clerks for the head letter-office in London, under the direction of a superintending president of the inland-letter department; and a comptroller of the foreign-letter office. Near 600 deputy-postmasters throughout the kingdom, act under one principal, and nine riding surveyors. There are also distinct officers and clerks, acting under an accountant-general and a receiver-general; as well as a separate establishment for the two-penny, formerly the penny-post, which since the abolition of Mr. Palmer's appointment of surveyor and comptroller-general, has been new modelled and greatly improved in all its branches. There is likewise a post-master-general of Scotland with a secretary, comptroller, surveyor, and a separate establishment of all the requisite officers and clerks at Edinburgh, acting under the orders of the joint postmasters-general in London. The annual expence of management is about 350,000*l.* and the gross produce exceeds 1,300,000*l.* a year.

POST, *two-penny*, a post established for the benefit of London and other parts adjacent, whereby any letter or small parcel is speedily and safely conveyed to and from all places within the bills of mortality, or within ten miles of the city. It is now managed by the general post office, and receiving-houses are established in most of the principal streets for the more convenient transmission of letters.

POST, a particular mode of travelling. A person is said to travel post, in contradistinction to common journey travelling, when in place of going on during his whole journey in the same vehicle, and with the same horses, he stops at different stages, to provide fresh horses, or carriages, for the sake of greater convenience and expedition. As he thus uses the same mode of travelling that is employed for the common post, he is said to travel post, or in post, i. e. in the manner of a post.

POST DISSEISIN, a writ for him that having recovered land or tenements by præcipe quod reddat, upon default of reddition, is again disseised by the former disseisor.

POSTEA, is the return of the proceedings by nisi prius into the court of common pleas after a verdict, and there afterwards recorded.

POSTERN, in fortification, is a small gate generally made in the angle of the flank of a bastion, or in that of the curtain, or near the orillon, descending into the ditch; by which the garrison may march in and out unperceived by the enemy, either to relieve the works, or to make private sallies, &c.

POSTULATE, in mathematics, &c. is described to be such an easy, and self-evident supposition, as needs no explication or illustration to render it intelligible; as, that a right line may be drawn from one point to another.

POTASH, commonly called the vegetable alkali, because it is obtained in an impure state by the incineration of vegetables. It is the hydrated protoxide of potassium.

Table of the saline product of one thousand pounds of ashes of the following vegetables

Saline products.

Stalks of Turkey wheat or maize, 198 lbs. Stalks of sun-flower, 349. Vine branches, 162.6. Elm, 166. Box, 78. Sallow, 102. Oak, 111. Aspen, 61. Beech, 219. Fir, 132. Fern cut in August, 116, or 125, according to Wildenheim. Wormwood, 748. Fumitory, 360. Heath, 115, Wildenheim.

On these tables Kirwan makes the following remarks:—

1. That in general weeds yield more ashes, and their ashes much more salt, than woods; and that consequently, as to salts of the vegetable alkali kind, as potash, pearl-ash, cashup, &c. neither America, Trieste, nor the northern countries, have any advantage over Ireland.

2. That of all weeds fumitory produces most salt, and next to it wormwood. But if we attend only to the quantity of salt in a given weight of ashes, the ashes of wormwood contain most. Trifolium fibrinum also produces more ashes and salt than fern.

The process for obtaining pot and pearl-ash is given by Kirwan, as follows:—

1. The weeds should be cut just before they seed, then spread, well dried, and gathered clean.

2. They should be burned within doors on a grate, and the ashes laid in a chest as fast as they are produced. If any charcoal be visible, it should be picked out, and thrown back into the fire. If the weeds be moist, much coal will be found. A close smothered fire, which has been recommended by some is very prejudicial.

3. They should be lixiviated with twelve times their weight of boiling water. A drop of the solution of corrosive sublimate will immediately discover when the water ceases to take up any more alkali. The earthy matter that remains is said to be a good manure for clayey soils.

4. The ley thus formed should be evaporated to dryness in iron pans. Two or three at least of these should be used, and the ley, as fast as it is concreted, passed from the one to the other. Thus, much time, is saved, as weak leys eva-

porate more quickly than the stronger The salt thus produced is of a dark colour, and contains much extractive matter, and being formed in iron pots is called potash.

5. This salt should then be carried to a reverberatory furnace, in which the extractive matter is burnt off, and much of the water dissipated: hence it generally loses from ten to fifteen per cent. of its weight. Particular care should be taken to prevent its melting, as the extractive matter would not then be perfectly consumed, and the alkali would form such a union with the earthy parts as could not easily be dissolved.

POTASSIUM. See Chemistry.

POTATOE. See Solanum.

POTTERY, the manufacture of earthen ware, or the art of making earthen vessels. The inferior kinds of porcelain, or pottery, are prepared by the same process as that which has been described under the word Porcelain, less pure, but more fusible materials being employed, and of course a less degree of heat being applied.

The better kinds of English stone-ware are composed of pipe-clay, and pounded flints. The yellow stone-ware is made of the same materials, in other proportions. The first is glazed by throwing sea-salt into the furnace in which it is baked, when the heat is strong; the salt is converted into vapour, and this, being applied to the surface of the stone-ware, vitrifies it, and forms an excellent glazing. The yellow stone-ware is glazed by dipping the baked ware in water, in which is suspended a mixture of pounded flint, glass, and oxide of lead. In the glazing of some kinds of stone-ware, oxide of tin enters into the composition with the oxide of lead, and gives a whiter glaze. All the coarser kinds of pottery are glazed with oxide of lead; this promoting so much the fusion and vitrification, that the low heat at which they are baked is sufficient.

POTSTONE, or lapis ollaris. Colour greenish-grey. Massive, and in granular concretions. Glistening. Fracture curved foliated. Translucent on the edges. Streak white. Soft. Sectile. Feels greasy. Somewhat tough. Sp. gr. 2.8. Its constituents are, silica 39, magnesia 16, oxide of iron 10, carbonic acid 20, water 10. It occurs in thick beds in primitive slate. It is found abundantly on the shores of the lake Como in Lombardy. It is fashioned into culinary vessels in Greenland.

POUNCE, gum sandarach pounded and sifted very fine, to rub on paper, in order to preserve it from sinking, and to make it more fit to write upon. Pounce is also a little heap of charcoal dust, inclosed in a piece of muslin or some other open stuff, to be passed over holes pricked in a work, in order to mark the lines or designs on paper, silk, &c. placed underneath; which are to be afterwards finished with a pen and ink, a needle, or the like.

POWER, in mechanics, denotes any force, whether of a man, a horse, a spring, the wind, water, &c. which being applied to a machine tends to produce motion.

Power *of attorney*, an instrument, or deed, whereby a person is authorised to act for another, either generally or in a specific transaction.

This power is always revoked by the death of the grantor, and no person who has a power of attorney can grant a power under him.

PRÆMUNIRE. This punishment is inflicted upon him who denies the king's supremacy the second time; upon him who affirms the authority of the pope, or refuses to take the oath of supremacy; upon such as are seditious talkers of the inheritance of the crown; and upon such as affirm that there is any obligation by any oath, covenant, or engagement whatsoever, to endeavour a change of government either in church or state; or that both or either house of parliament have or has a legislative power without the king, &c.

PRAYER, a petition offered to the Almighty for some future favour. This is not the place for an essay on the important subject of prayer, but surely it may be allowable to remark that all prayer, in order to its being acceptable before the Great Being to whom it is addressed, must be presented in faith and sincerity, otherwise it is only an insult offered to the Divine Majesty; and this, it is to be feared, is the case with the greater part of the public prayers with which our ears have become familiar by long use.

PREBENDARY, an ecclesiastic who enjoys a prebend. The difference between a prebendary and a canon is, that the former receives his prebend, in consideration of his officiating in the church; but the latter merely by his being received into the cathedral or college.

PRECEDENCE, or Precedency, a place of honour to which a person is entitled: this is either of courtesy or of right. The former is that which is due to age, estate, &c. which is regulated by custom and civility: the latter is settled by authority, and when broken in upon gives an action at law.

The order of precedency, which is observed in general, is thus: that persons of every degree of honour or dignity take place according to the seniority of their creation, and not of years, unless they are descended from the blood-royal; in which case, they have place of all others of the same degree.

PRECENTOR, a dignitary in cathedrals, popularly called the chantor, or master of the choir.

PRECESSION *of the equinoxes*, is a very slow motion of them, by which they change their place, going from east to west, or backward, *in antecedentia*, as astronomers call it, or contrary to the order of the signs.

PREDICATE, in logic, that part of a proposition which affirms or denies something of the subject: thus, in these propositions, snow is white, ink is not white, whiteness is the predicate which is affirmed of snow, and denied of ink.

PREROGATIVE, is a word of large extent, including all the rights and privileges which by law the king has as chief of the common wealth, and as intrusted with the execution of the laws.

Prerogative *court*; the court wherein all wills are proved, and all administrations taken which belong to the archbishop by his prerogative; that is, in case where the deceased had goods of any considerable value out of the diocese wherein he died; and that value is ordinarily 5*l.* except it is otherwise by composition between the said archbishop and some other bishop, as in the diocese of London it is 10*l.*

PRESBYTERIANS, a sect of protestants, so called from their maintaining that the government of the church appointed in the new testament was by presbyteries; that is, by ministers and ruling elders, associated for its government and discipline.

But the appellation presbyterian, is in England appropriated to a large denomination of dissenters, who have no attachment to the Scotch mode of church government any more than to episcopacy among us; and, therefore, to this body of Christians the term presbyterian is improperly applied.

PRESS, the name given to a machine for compressing any substance or substances together, and retaining them under that compression as long as may be requisite.

PRIMITIVE, in grammar, is a root or original word in a language, in contradistinction to derivative. Thus, *God* is a primitive, *godly*, derivative, and *god like* a compound.

PRIMOGENITURE, the right of first-born. This right seems to be an unjust prerogative, and contrary to the natural right; for since it is birth alone gives children a title to the paternal succession, the chance of primogeniture should not throw any inequality among them.

PRIMUM *mobile*, in the Ptolemaic astronomy, the ninth or highest sphere of the heavens, whose centre is that of the universe.

PRINCE, in polity, a person invested with the supreme command of a state, independent of any other. Prince also denotes a person who is a sovereign in his own territories, yet holds of some other as his superior; such are the princes of Germany, who, though absolute in their respective principalities, are bound to the emperor in certain services. Prince also denotes the issue of princes, or those of the royal family. In France, they are called princes of the blood.

PRINCIPAL, the chief and most necessary part of a thing. In commerce, principal is the capital of a sum due or lent, so called in opposition to interest. It also denotes the first fund put by partners into a common stock, by which it is distinguished from the calls or accessions afterwards required.

PRINT, the impression taken from a copper-plate.

PRINTING, the art of taking impressions from characters or figures moveable or immoveable, on paper, linen, silk, &c. There are four kinds of printing, one from moveable letters for books; another from copper plates, for pictures; a third from blocks, in which the representation of birds, flowers, &c. are cut for printing calicoes, linens, &c. and the fourth by solid pages cast for the printing of books; the first, called common press-printing, the second rolling press-printing, the third calico, &c. printing; and the last stereotype printing.

The method of printing from moveable type is now so well known, that we need not here offer a detail of the process. The method of printing linen and paper for hangings, has been practised in the East from time immemorial. Printing from wooden blocks has been known in China for more than 1660 years. When a work is to be stereotyped, it is fairly transcribed upon a thin transparent paper. Each leaf is then reversed, and fixed upon a smooth block of hard wood, where the characters are engraven in relief; there is therefore a separate block for each page. The Italians, Germans, Flemings, and Dutch, began to engrave on wood and copper, about the end of the fourteenth century, and inscriptions in relief upon monuments and altars, in cloisters, and over church porches, became models for block-printing; and the letters upon painted windows, strongly resemble those in books of images.

The invention of cards in France, in the reign of Charles the Wise, about the year 1376, was an intermediate step. They were soon introduced into Spain, Italy, Germany, and England. At first the cards were painted; afterwards, about the year 1400, a method was devised of printing them from blocks, and to this we may trace the art of printing. From the next step resulted the books of images, printed from wooden blocks; one side of the leaf only was impressed, the corresponding text was placed below, at the side, or it issued from the mouth of the figure; the idea of stereotype printing is, therefore, not of modern origin.

Towards the close of the seventeenth century, this art, therefore, was practised in Holland. William Ged, of Edinburgh, in the year 1725, made the first use of this art in Britain; but owing to some defect in the plan, or want of skill in its execution, the invention attracted little notice.

In 1782, Mr. Alexander Tilloch, editor of the Philosophical Magazine, revived, or rather re-discovered this art; for he is said to have been ignorant of Ged's contrivance long after he had announced his own. In the subsequent year, he took out a patent for it, in conjunction with Mr. Andrew Foulis, printer to the university of Glasgow. Mr. Tilloch, however, removing to London, the concern was dropped altogether; not, however, until several small volumes had been stereotyped and printed, under the direction of these gentlemen.

About the year 1789, M. Didot, of Paris, applied the stereotype art to logarithmic tables, and afterwards to several of the Latin classics, and to various French publications; he introduced several important improvements, which render his mode more convenient and useful than that of any of his predecessors. The French, as usual, claim the merit of the invention, but our readers must soon perceive to whom this honour properly belongs. The name stereotype seems first to have been employed by M. Didot; it is derived from στερεος, *solidus*, and τυπος, *typus*, denoting that the types were soldered, or otherwise connected together.

Some years after Mr. Tilloch had given up the prosecution of this art, Mr. Wilson, a printer, of London, engaged with Earl Stanhope, for the purpose of bringing it to perfection, and eventually to establish it in this country. After two years application, the stereotype art was, in January 1804, with the approbation of Earl Stanhope, offered to the University of Cambridge, and accepted by them. Their bibles, testaments, and prayer-books, were printed in this manner. The plan was followed by the Bible Society, and other persons, for printing books of extensive sale and permanent demand, as bibles, dictionaries, grammars, &c. &c. The stereotype art has much the advantage of common printing for such purposes, wherein no alteration, as to plan or size, is allowed to take place. But for the common and general purposes of the

art of printing, the method by moveable types is incontestably the best.

The process of preparing the stereotype is now much improved, and is in general conducted thus. A page of any work intended to be stereotyped, is set up in the usual manner, with the ordinary moveable types. From this page, when corrected, a mould in plaster, the basis of which is gypsum, is taken off, and from this mould an impression is cast in the ordinary type metal, from which the printing is made. In this way each page of the work is set up, and from these casts, plates are procured, from which impressions may be made exactly the same in every particular as that from the moveable types originally set up.

A stereotype plate, therefore, is simply a fac-simile of the page from which it was taken, with this advantage, that it does not require to be more than the seventh or eighth part of the thickness or height of the common types.

After the plate has been cast, several little imperfections appear on it, which are easily removed by appropriate tools; the back of the plate is then turned perfectly level in a lathe, that it may lie flat in the press.

In nothing connected with mechanical science, has there been more emulation displayed than in the construction of the printing press. We have now the improved Stanhope press, the Columbian press, Barclay's American press, Mr. Ruthven's press; Bacon and Donkin's, Applegarth's, and Bensley's printing machines, with others of less note. All these possess their peculiar advantages over the old common printing press; but mature experience seems to have given a decided preference to the Columbian press. This press was invented by Mr. George Clymer, of Philadelphia, now of London.

The principal excellences of this press are the following. The power is obtained by a combination of levers instead of a screw, and is much greater than that of any other printing press. This power is susceptible of gradation to the smallest as well as to the largest forms, and is equally well adapted to all kinds of work, from the smallest card to the heaviest double royal sheets. In this press also an extra degree of care is taken, to make the surface of the iron platten, and that of the iron bed for the types, perfectly level; thus an equal pressure on every part of the sheet is insured. It is found also that by this press much less injury is done to the types than by any other press, since from its great power a very sharp impression may be obtained without sinking into the paper.

PRINTERS, *Marks of,* are those marks used by the correctors of the press, to point out the errors of the proof sheets, that the compositor may amend them before the work is printed off.

The corrections are placed on the margin of every page, against the line in which the faults are found: and there are different characters used to express different corrections: thus ₰ is put for dele, to intimate that something, as a point, letter, word, &c. dashed in that line, is to be taken out. If any thing is to be inserted, the place is to be marked thus ∧ and the thing to be inserted added in the margin. When there are two or more corrections in the same line, then they are all separated in the margin by little bars, thus /. If a space is omitted, its place is marked with a caret, and in the margin thus #. When a letter is inverted, it is expressed in the margin thus ℘. When any thing is to be transposed it is directed thus, Extraordinary scarce ever fail of attainments exciting envy, for Extraordinary attainments scarcely ever fail of exciting envy, and in the margin is added *trs.* If Italic characters are to be changed for Roman, or vice versa, a line is drawn thus — under the letters, and *Rom.* or *Ital.* is written in the margin. If a space, or an m or an n quadrat, stick up, and print black, it is marked in the margin with a dash, thus | If a word, sentence, or paragraph, is entirely omitted, the place is marked with a caret, and in the margin is put the word *out.* If the letters of a word stand too far asunder, a line is drawn under them, and in the margin is put a crooked line or hook, thus ‿. There are many other marks used in correcting, as ✓ for superior, *cap.* for capital, *l. c.* for lower-case, &c.

PRISM, in geometry, an oblong solid, contained under more than four planes, whose bases are equal, parallel, and alike situated.

Prism, in dioptrics, a triangular glass-prism, much used in experiments about the nature of light and colours. See Optics.

PRISTIS, or saw-fish, a genus of fishes of the order chondropterigii: the generic character is, snout long, flat, spinous down the edges, spiracles lateral; body oblong, roundish, covered with a rough, coriaceous skin; mouth beneath; nostrils before the mouth, half-covered with a membranaceous flap; behind the eyes two oval orifices; ventral fins approximate. There are five species.

PRIVATEERS, in maritime affairs, a kind of private ships of war, fitted out by private persons at their own expense; who have leave granted them to keep what they can take from the enemy, allowing the admiral his share.

PRIVY *council,* is the principal council belonging to the king, and is generally called by way of eminence the council. Privy counsellors are made by the king's nomination, without either patent or grant; and on taking the necessary oaths they become immediately privy counsellors, during the life of the king that chooses them, but subject to removal at his discretion.

PRIZE, in sea affairs, a vessel taken from the enemies of a state, or from pirates, either by a man-of-war, a privateer, &c. having a commission for that purpose. Vessels are looked on as prize, if they fight under any other standard than that of the state from which they have their commission.

PROBATE. See Will.

PROBE, a surgeon's instrument for examining the circumstances of wounds, &c. See Surgery.

PROBLEM, in logic, is a proposition that neither appears absolutely true nor false; and consequently may be asserted either in the affirmative or negative.

PROBLEMATICAL RESOLUTION, in algebra, a method of solving difficult questions by certain rules called canons.

PROBOSCIS, in natural history, is the trunk or snout of an elephant, and some other beasts and insects.

PROCEDENDO, in law, a writ whereby a plea or cause, formerly called from an inferior court to the court of chancery, king's bench, or court of common pleas, by writ of privilege, habeas corpus, or certiorari, is released and returned to the other court to be proceeded in, upon its appearing that the defendant has no cause of privilege, or that the matter in the party's allegation is not well proved.

PROCELLARIA, in ornithology, a genus of birds belonging to the order of anseres. The beak is somewhat compressed, and without teeth; the mandibles are equal, the superior one being crooked at the point; the feet are palmated, the hind claw being sessile, without any toe. Mr. Latham enumerates twenty-four species, which are principally distinguished by their colour.

PROCTOR, a person commissioned to manage another person's cause in any court of the civil or ecclesiastical law. The proctors of the clergy, are the representatives chosen by the clergy to sit in the lower house of convocation: of these there are two for each diocese, and one for each collegiate church.

PROCURATOR, a person who has a charge committed to him to act for another. Thus the proxies of the lords in parliament are, in our law-books, called procurators; the bishops are sometimes called procuratores ecclesiarum; and the representatives sent by the clergy to convocation, procuratores cleiici.

PROCYON, in astronomy, a fixed star of the second magnitude in the constellation called canis minor. See Canis.

PRODUCING, in geometry, signifies the drawing out a line farther till it has any assigned length.

PRODUCT, in arithmetic and geometry, the factum of two or more numbers, or lines, &c. into one another: thus 5 × 4 = 20 the product required.

PROFILE, the draught of a building, fortification, &c. See Architecture.

Profile, also denotes the outline of a figure, building, member of architecture, &c.

Profile, in sculpture and painting, denotes a head, portrait, &c., when represented sideways, or in a side view. On almost all medals, faces are represented in profile.

PROGRESSION, an orderly advancing or proceeding in the same manner, course, tenor, proportion, &c.

Progression is either arithmetical or geometrical.

Progression, *Arithmetical*, is a series of quantities proceeding by continued equal differences, either increasing or decreasing. Thus,

increasing 1, 3, 5, 7, 9, &c. or
decreasing 21, 18, 15, 12, 9, &c.;

where the former progression increases continually by the common difference 2, and the latter series or progression decreases continually by the common difference 3.

1. And hence to construct an arithmetical progression, from any given first term, and with a given common difference; add the common difference to the first term, to give the 2nd; to the 2nd, to give the 3rd; to the 3rd, to give the 4th; and so on; when the series is ascending or increasing: but subtract the common difference continually, when the series is a descending one.

PROHIBITION, is a writ properly issuing only out of the court of king's bench, being the king's prerogative writ; but, for the furtherance of justice, it may now also be had in some cases out of the court of chancery, common pleas, or exchequer, directed to the judge and parties of a suit in an inferior court, commanding them to cease from the prosecution thereof, upon a suggestion, that either the cases originally, or some collateral matter arising therein, does not belong to that jurisdiction, but the cognizance of some other court.

PROJECTILES, the science of the motion, velocity, flight, range, &c. of a projectile put into violent motion by some external cause, as the force of gunpowder, &c. This is the foundation of gunnery, under which article may be found all that relates peculiarly to that branch.

PROJECTION. In perspective, projection is the appearance or representation of an object on the perspective plane. The projection of the sphere is either orthographic, or stereographic. The former, or orthographic projection, supposes the eye placed at an infinite distance; whereas, in the stereographic projection, it is supposed to be only 90 degrees distant from the primitive circle, or placed in its pole, and thence viewing the circles on the sphere. The primitive circle is that great circle which limits or bounds the representation or projection; and the place of the eye is called the projecting point.

PROLATE, in geometry, an epithet applied to a spheroid produced by the revolution of a semi-ellipsis about its larger diameter.

PROMISE, is where, upon a valuable consideration, persons bind themselves by words to do or perform such a thing agreed on; it is in the nature of a verbal covenant, and wants only the solemnity of writing and sealing to make it absolutely the same. Yet for the breach of it, the remedy is different; for instead of an action of covenant, there lies only an action upon the case, the damages whereof are to be estimated and determined by the jury.

PROMISSORY NOTE. See Bills of Exchange.

PRONOUN, in grammar, a declinable part of speech, which being put instead of a noun, points out some person or thing.

PROOF, the shewing or making plain the truth of any matter alleged; either in giving evidence to a jury on a trial, or else on interrogatories, or by copies of records, or exemplifications of them.

PROPORTION, is often confounded with ratio; but they are quite different things. For ratio is properly the relation of two magnitudes or quantities of one and the same kind; as the ratio of 4 to 8, or 15 to 30, or of 1 to 2, and so implies or respects only two terms or things. But proportion respects four terms or things, or two ratios which have each two terms: though the middle term may be common to both ratios, and then the proportion is expressed by three terms only, as 4, 8, 64, where 4 is to 8 as 8 to 64.

PROPOSITION, in logic, part of an argument wherein some quality, either negative or positive, is attributed to a subject.

PROSODY, that part of grammar which treats of the quantities and accents of syllables and the manner of making verses.

PROSOPŒIA, a figure in rhetoric, whereby we raise qualities, or things inanimate, into persons.

PROTEST, when one openly affirms, that he does either not at all, or but conditionally, yield his consent to any act, or unto the proceeding of a judge in court wherein his jurisdiction is doubtful, or to answer upon his oath any farther than by law he is bound.

PROTEST, is also that act by which the holder of a foreign bill of exchange declares that such bill is dishonoured.

PROTEST, is also that act of a master, on his arrival with his ship from parts beyond the seas, to save him and his owners harmless and indemnified from any damage sustained in the goods of her lading, on account of storms. See BILLS of EXCHANGE, and INSURANCE.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because in 1529, they protested against a decree of the emperor Charles V. and the diet of Spires; declaring that they appealed to a general council. The same name also has been given to those of the sentiments of Calvin, and is now become a common denomination for all those of the reformed churches.

PROTHONOTARY, a term which properly signifies first notary, and which was anciently the title of the principal notaries of the emperors of Constantinople.

Prothonotary with us is used for an officer in the king's bench and common pleas; the former of which courts has one, and the latter three.

PROTESTATION, is a form in pleading, when one does not directly affirm or deny any thing that is alleged by another, or which he himself alleges.

PROTRACTOR, is the name of an instrument used for protracting or laying down on paper the angles of a field, or other figure. The protractor is a small semicircle of brass, or other solid matter, the limb or circumference of which is nicely divided into one hundred and eighty degrees: it serves not only to draw angles on paper, or any plane, but also to examine the extent of those already laid down.

PROVIDENCE, the conduct and direction of the several parts of the universe by a superior intelligent being.

On the subject of providence an eminent philosopher and profound Theologian has the following truly appropriate remarks:

"It is Jehovah from whom order is derived, hence it may be said that Jehovah is order itself; for from himself, he ruleth over order, not in the universal only, as is commonly supposed, but in the most particular things; for particulars are what constitute an universal, and to talk of an universal, and thence to separate particulars, would be like talking of a whole in which there are no parts, and thus like talking of something in which there is nothing; consequently it is most false, and merely notional, to say that the Lord's providence is universal, and not at the same time most particular; for to provide and rule in the universal, and not at the same time in the most particular things, is not to provide nor rule at all.

This is philosophically true, and yet it is surprising that philosophers themselves, even the most sublime and exalted, conceive and think otherwise."

PROVISO, in law, a condition inserted in a deed, upon the observance whereof the validity of the deed depends.

PROVOST, an officer, whereof there are divers kinds, civil, military, &c.

PROVOST, of a city or town, is the chief municipal magistrate in several trading cities, particularly Edinburgh, Glasgow, &c. being much the same with the mayor in other places. He presides in city-courts, and, together with the baillies, who are his deputies, determines in all differences that arise among citizens.

PROW, in navigation, denotes the head or fore part of a ship, particularly in a galley, being that which is opposite to the poop or stern. In the middle of the prow is the beak that cuts the water, on the top of which is commonly some figure or hieroglyphic.

PRUNELLA, a genus of the gymnospermia order, in the didynamia class of plants; and in the natural method ranking under the 12th order, holoraceæ. The filaments are bifurcated, the stigma is bifid. There are three species, herbs of Europe.

PRUNELLÆ, in pharmacy, a preparation of purified saltpetre.

PRUNES, in commerce, are plums dried in the sun-shine, or in an oven.

PRUNING, in gardening and agriculture, is the lopping off the superfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular. Pruning though an operation of very general use, is nevertheless rightly understood by few; nor can it be learned by rote, or indeed wholly by books, but requires a strict observation of the different manners of growth of the several sorts of fruit trees; the proper method of doing which cannot be known, without carefully observing how each kind is naturally disposed to produce its fruit; for some do this on the same year's wood as vines; others for the most part upon the former year's wood, as peaches, nectarines, &c. and others, upon spurs which are produced upon wood of three, four, &c. to fifteen or twenty years old, as pears, plums, cherries, &c. therefore, in order to the right management of fruit trees, provision should always be made to have a sufficient quantity of bearing wood in every part of the trees, and at the same time there should not be a superfluity of useless branches, which would exhaust the strength of the trees, and cause them to decay in a few years. The reasons for pruning of fruit-trees, are, 1. To preserve them longer in a vigorous bearing state; 2. To render them more beautiful; and, 3. To cause the fruit to be larger and better tasted.

PRUNUS, a genus of the monogynia order, in the icosandria class of plants; and in the natural method ranking under the 36th order, pomaceæ. The calyx is quinquefid, inferior: there are five petals; the fruit is a plum, having a kernel with prominent sutures. There are 33 species.

PRUSSIC ACID, is one of the most powerful and important of the acids. The following brief account of it is from the Chemical Dictionary of Dr. Ure, to which we would refer the reader for a most interesting account of this remarkable substance.

The combination of this acid with iron was

long known and used as a pigment by the name of Prussian blue, before its nature was understood. Macquer first found that alkalis would decompose Prussian blue, by separating the iron from the principle, with which it was combined in it, and which he supposed to be phlogiston. In consequence, the prussiate of potash was long called *phlogisticated alkali*. Bergman, however, from a more scientific consideration of its properties, ranked it among the acids; and, as early as 1772, Sage announced, that this animal acid, as he called it, formed with the alkalis neutral salts, that with potash forming octaedral crystals, and that with soda rhomboids or hexagonal laminæ. About the same time Scheele instituted a series of sagacious experiments, not only to obtain the acid separate, which he effected, but also to ascertain its constituent principles.

Scheele's method is this: Mix four ounces of prussian blue with two of red oxide of mercury prepared by nitric acid, and boil them in twelve ounces by weight of water, till the whole becomes colourless; filter the liquor, and add to it one ounce of clean iron filings, and six or seven drams of sulphuric acid. Draw off by distillation about a fourth of the liquor, which will be Prussic acid; though, as it is liable to be contaminated with a portion of sulphuric, to render it pure, it may be rectified by redistilling it from carbonate of lime.

This prussic acid has a strong smell of peach blossoms, or bitter almonds; its taste is at first sweetish, then acrid, hot, and virulent, and excites coughing; it has a strong tendency to assume the form of gas; it has been decomposed in a high temperature, and by the contact of light, into carbonic acid, ammonia, and carburetted hydrogen. It does not completely neutralize alkalis, and is displaced even by the carbonic acid; it has no action upon metals, but unites with their oxides, and forms salts for the most part insoluble; it likewise unites into triple salts with these oxides and alkalis: the oxygenated muriatic acid decomposes it.

From the experiments of M. Magendie it appears, that the pure hydrocyanic acid is the most violent of all poisons. When a rod dipped into it is brought in contact with the tongue of an animal, death ensues before the rod can be withdrawn. If a bird be held a moment over the mouth of a phial containing this acid, it dies. In the Annales de Chimie for 1814 we find this notice: M. B. Professor of Chemistry, left by accident on a table, a flask containing alcohol impregnated with Prussic acid; the servant, enticed by the agreeable flavour of the liquid, swallowed a small glass of it. In two minutes she dropped down dead, as if struck with apoplexy. The body was not examined.

"Scharinger, a professor at Vienna," says Orfila, "prepared six or seven months ago a pure and concentrated prussic acid; he spread a certain quantity of it on his naked arm, and died a little time after."

Dr. Magendie has, however, ventured to introduce its employment into medicine. He found it beneficial against phthisis and chronic catarrhs. His formula is the following:—

Mix one part of the pure prussic or hydrocyanic acid of M. Gay Lussac with 8½ of water by weight. To this mixture he gives the name of medicinal Prussic acid.

Of this he takes	1 gros.	or	59 gr. Troy
Distilled water,	1 lb.	or	7560 grs.
Pure sugar,	1½ oz.	or	708¾ gr.

And mixing the ingredients well together, he administers a table-spoonful every morning and evening.

PSITTACUS, or *parrot*, a genus belonging to the order of picæ. The bill in this genus is hooked from the base; and the upper mandible is moveable: the nostrils are round, placed in the base of the bill, which in some species is furnished with a kind of cere; the tongue is broad, and blunt at one end: the head is large, and the crown flat; the legs are short, the toes placed two before and two behind. Parrots are found almost every where within the tropics; and in their natural state they live on fruits and seeds, though, when tame, they will eat flesh and even fish.

PTOLEMAIC, or *Ptolemean system of astronomy*, is that invented by Claudius Ptolemæus, a celebrated astronomer and mathematician of Pelusium in Egypt, who lived at the beginning of the second century of the Christian æra.

This hypothesis supposes the earth immoveably fixed in the centre, not of the world only, but also of the universe; and that the sun, the moon, the planets, and stars, all move about it from east to west, once in 24 hours, in the order following: viz. the Moon next to the Earth, then Mercury, Venus, the Sun, Mars, Jupiter, Saturn, the fixed stars, the first and second crystalline heavens, and above all, the fiction of their primum mobile.

PUDDING *stone*, in chemistry, a term invented by English lapidaries to designate one particular mineral aggregate, consisting of oblong and rounded pebbles of flint, about the size of almonds, imbedded in a hard siliceous cement. The pebbles are usually black, and the cement a light yellowish brown. It is capable of receiving a very high polish, and is used in ornamental works. It is found chiefly in Essex.

PULEX, in natural history, the *flea*, a genus of insects of the order aptera. Generic character: mouth without jaws or feelers, with a long inflected proboscis, covered at the base with two ovate laminæ; the sheat two-valved, five-jointed, and concealing a single bristle; lip rounded and fringed with reflected prickles; antennæ projecting, moniliform; two eyes; abdomen compressed; six legs formed for leaping.

PULLEY, in mechanics, one of the mechanical powers, called by seamen a tackle. See Mechanics.

PULSE, in the animal economy denotes the beating or throbbing of the heart and arteries.

Pulse. See Legumen.

PUMICE-*stone*, or *porous glasses*. When the compact glasses are exposed to the heat of our furnaces, they emit a great number of air-bubbles, which renders them porous: such is the origin of pumice. It has the same base as compact glass. The texture is fibrous; the fibres have a silky lustre. Colours various, white, brown, yellow, black. Before the blow-pipe, they melt into a white enamel.

PUMP. See Hydraulics.

PUNCH, an instrument of iron or steel, used

in several arts for the piercing or stamping holes in plates of metals, &c. being so contrived as not only to perforate, but to cut out and take away the piece. The punch is a principal instrument of the metal button-makers, wafer-makers, patch-makers, shoe-makers, &c.

PUNCHEON, a little block or piece of steel, on one end whereof is some figure, letter, or mark, engraven either in creux or relievo, impressions whereof are taken on metal, or some other matter, by striking it with a hammer on the end not engraved. There are various kinds of these puncheons used in the mechanical arts; such for instance are those of the goldsmiths, cutlers, pewterers, &c.

PURCHASE, in law, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance. A joint purchase is when two or more persons join together in the purchase.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of their professing to follow the pure word of God, in opposition to all traditions and human constitutions.

PURPLE, a colour composed of a mixture of red and blue. See DYEING.

PURSER, an officer aboard a man of war, who receives her victuals from the victualler, sees that it is well stowed, and keeps an account of what he every day delivers to the steward.

PUS. The liquid called pus is secreted from the surface of an inflamed part, and usually moderates and terminates the inflammation. It assumes different appearances according to the state of the sore. When it indicates a healing sore, it is called healthy or good-conditioned pus. This liquid possesses the following properties:

It is of a yellowish-white colour, and of the consistence of cream. Its taste is insipid, and it has no taste when cold. Before the microscope it exhibits the appearance of white globules swimming in a transparent fluid.

PUTREFACTION. The spontaneous decomposition of such animal or vegetable matters, as exhale a fetid smell, is called putrefaction. The solid and fluid matters are resolved into gaseous compounds and vapours which escape, and into an earthy residuum. As the grand resolvent of organic matter is water, its abstraction by drying, or fixation by cold, by salt, sugar, spices, &c. will counteract the process of putrefaction. The atmospheric air is also active in putrefaction; hence, its exclusion favours the preservation of food; on which principle, some patents have been obtained.

PUTTY, in the arts. When tin is melted in an open vessel, its surface soon becomes covered with a grey powder, which is an oxide of the metal. If the heat is continued, the colour of the powder gradually changes, and at last becomes yellow. In this state it is known by the name of putty, and employed in polishing glass and other hard substances.

PUTTY is also a kind of paste compounded of whiting and linseed-oil, beaten together to the consistence of a thick dough. It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots, &c.

PUZZULANA or POZZOLANA, *terra*, or *terrus*, is a greyish kind of earth used in Italy for building under water. The best is found about Puteoli, Baiæ, and Cumæ, in the kingdom of Naples, from the first of which places it derives its name. It is supposed to be a volcanic product, composed of heterogeneous substances thrown out from the burning mouths of volcanoes in the form of ashes; sometimes in such large quantities, and with so great violence, that whole provinces have been covered with it at a considerable distance.

PYRAMID, in geometry, a solid standing on a triangular, square or polygonal basis, and terminating in a point at the top; or, according to Euclid, it is a solid figure consisting of several triangles, whose bases are all in the same plane, and which have one common vertex.

There are several pyramids in Egypt, but those at Gizeh are the most gigantic; and the most enormous, or the great pyramid, is situated near Memphis. Herodotus says, he was informed the latter covered the remains of Cheops, and another adjoining those of his brother Cephrenes, who succeeded him; the first only having inner galleries, or passages. Although much dependence cannot be placed upon the further accounts of this ancient writer, it seems highly probable that an 100,000 men may have been constantly employed, for 20 years, in efecting the immense pile, and that Cheops became detested by the people, who were thus taken from more useful employments, as well as by the bulk of the population, who found the taxes demanded of them appropriated to a purpose utterly unproductive of future advantage.

PYRITES, a genus of inflammable substances composed of sulphur, which has dissolved or saturated itself with metals. Thus there are many kinds of pyrites; as of gold, arsenic, iron, &c.

PYROLIGNEOUS *acid*, or, as it is sometimes termed, *vinegar of wood*, is a substance likely to become of great use as an animal antiseptic. From the low price at which it is sold it is adapted for general use; more particularly, as it not only preserves the food from putrefaction, but also gives to it that smoky and acid taste peculiar to well dried hams and red-herrings. Indeed, the only difference in using this acid, and drying by turf or wood smoke, seems to be merely the mode of operation; for in both cases this acid is the agent employed. In one case, the animal substance is acted on during the distillation of the acid and in the other the already formed acid is applied to the substance by immersion.

This acid, the product of the distillation of wood, is now well known in Britain as an article of commerce, and in its native state is a liquid of the colour of white wine, possessing a strong acid and slightly astringent taste, combined with an empyreumatic smell. When allowed to remain in a state of rest for eight or ten days, tar of a black colour subsides, and the acid is then comparatively transparent. To purify it further, it undergoes the process of distillation, by which it is freed from a still greater portion of the tar with which it is combined, and is thus rendered still more transparent. But though the process of distillation be repeated without end, it will never be freed from the volatile oil with which it is combined,

and which is the cause of the empyreuma constantly attending it. In short, it contains the same properties for the preservation of animal matters from putrefaction as smoking them by wood does, which is practised at present by the most barbarous nations, and which has been handed down from the remotest ages of antiquity.

PYROMETER. The most celebrated instrument for measuring high temperatures is that invented by the late Mr. Wedgewood, founded on the principle, that clay progressively contracts in its dimensions, as it is progressively exposed to higher degrees of heat. He formed his white porcelain clay into small cylindrical pieces, in a mould, which, when they were baked in a dull red heat, just fitted into the opening of two brass bars, fixed to a brass plate, so as to form a tapering space between them. This space is graduated; and the farther the pyrometric clay gauge can enter, the greater heat does it indicate. The two converging rules are placed at a distance of 0.5 of an inch at the commencement of the scale, and of 0.3 at the end.

PYROPHORUS. By this name is denoted an artificial product, which takes fire or becomes ignited on exposure to the air. Hence, in the German language, it has obtained the name of luft-zunder, or air-tinder. It is prepared from alum by calcination, with the addition of various inflammable substances.

Dr. Ure has made a very good pyrophorus by simply mixing three parts of alum with one of wheat-flour, calcining them in a common phial till the blue flame disappeared; and has kept it in the same phial, well stopped with a good cork when cold.

If this powder be exposed to the atmosphere, the sulphuret attracts moisture from the air, and generates sufficient heat to kindle the carbonaceous matter mingled with it.

PYROTECHNY, the art of fire, or a science which teaches the management and application of fire in several operations. But the term is more particularly used to denote the doctrine of artificial fireworks.

On this subject, which would require a distinct volume, we can only here offer a brief outline, at the same time referring the student to an able article under this head in the Edinburgh Encyclopædia.

The principal ingredients used in the process of artificial firework making, are,—1. saltpetre, purified for the purpose; 2. sulphur; and 3. charcoal. Gunpowder is likewise used in the composition of fire-works, being first ground, or, as it is technically termed, mealed. Camphor and gum-benzoin are employed as ingredients in odoriferous fire-works. The proportions of the materials differ very much in different fire-works, and the utmost care and precaution are necessary in the working them to a state fit for use, and then in the mixing. In this work we cannot enter on the subject with a sufficient degree of minuteness to teach the method of making fire-works, and we shall therefore content ourselves with a brief notice of the proportions of the materials in some of the more common, and more interesting articles in use.

The charges for sky-rockets are made of saltpetre, four pounds; brimstone, one pound; and charcoal one pound and a half; or by another direction, saltpetre, four pounds; brimstone, one pound and a half; charcoal, twelve ounces; and meal powder, two ounces. These proportions vary again according to the size of the rocket; in rockets of four ounces, mealed-powder, saltpetre, and charcoal, are used in the proportions of 10 : 2 and 1; but in very large rockets the proportions are saltpetre, four; mealed-powder and sulphur one each. When stars are wanted, camphor, alcohol, antimony, and other ingredients are required according as the stars are to be blue, white &c. In some cases gold and silver rain is required; then brass-dust, steel-dust, saw-dust, &c. enter into the composition; hence the varieties may be almost indefinite. With respect to colour, sulphur gives a blue, camphor a white or pale colour, saltpetre a clear white yellow, sal-ammoniac a green, antimony a reddish, rosin a copper colour.

To the above may be added NITRATE of STRONTIAN, the effect of which is to produce a fine crimson light of indescribable richness and beauty. See STRONTIAN.

PYRUS, the *pear tree*, a genus of the pentagynia order, in the icosandria class of plants, and in the natural method ranking under the 36th order pomaceæ. The calyx is quinquefid; there are five petals; the fruit is an apple, inferior, quinquelocular, and polyspermous. To this genus Linnæus has joined the apple and quince. There are thirteen species.

PYTHIAN GAMES, in antiquity, solemn games celebrated near Delphi in honour of Apollo, and in remembrance of his having killed the serpent Python.

These were held every two years, about the month of Elaphebolion, which answers to our February.

Q.

Q, or q, the sixteenth letter of our alphabet. As a numeral, it stands for 500; and with a dash over it, thus $\bar{Q}$, for 500,000. Used as an abbreviature, q signifies quantity or quantum: thus, among physicians, q. pl. is quantum placet, *i. e.* as much as you please of a thing; and q. s. quantum sufficit, *i. e.* as much as is necessary. Q. E. D. among mathematicians, is quod erat demonstrandum, *i. e.* which was to be demonstrated; and Q. E. F. quod erat faciendum, *i. e.* which was to be done

Q. D. among grammarians, is quasi dictum, *i. e.* as if it was said, or, as who should say. In the notes of the ancients, Q stands for Quintus or Quintius; Q. B. V. for quod bene vertat Q. S. S. S. for quæ supra scripta sunt; Q. M. for Quintus Mutius, or quomodo; Quint. for Quintilius; and Quæs. for quæstor.

QUACK, a medical impostor, who "for the good of the public," and "by the blessing of God," undertakes with his powders, potions, or balsam, to cure "all disorders." Thus, igno

rance and blasphemy unite in picking the pockets and ruining the constitution of thousands of credulous people in this and other countries. The pretension to infallibility in any one medicine, as a cure for any one disorder, is next to absurd: much more ridiculous is it then to suppose, that any medicine will remove all kinds of complaints.

QUADRANGLE, in geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles. To the class of quadrangles belong the square, parallelogram, trapesium, rhombus, and rhomboides. A square is a regular quadrangle; a trapesium an irregular one.

QUADRANS, the quarter or fourth part of any thing, particularly the *as*, or pound.

QUADRANT, denotes a mathematical instrument, of great service in astronomy, and, consequently, in navigation, for taking the altitudes of the sun and stars; as also for taking angles in surveying. Those chiefly in use, are Adams's, Cole's, Gunter's, Hadley's, Sutton's, or Collins's, the horodictical, the sinical, the astronomical, and the common surveying quadrant.

Of the common Quadrant.

This instrument, ABC, fig. 1, Plate XLVI. is made of brass, or wood, &c. the limb or arch of which BC is divided into 90°, and each of these is farther divided into as many equal parts as the space will allow, either diagonally or otherwise. To one of the radii AC, are fitted two moveable sights; and to the centre is sometimes also annexed a label, or moveable index, AD, bearing two other sights; but, instead of these last sights, there is sometimes fitted a telescope. Also from the centre hangs a thread with a plummet; and on the under side or face of the instrument are fitted a ball and socket, by means of which it may be put into any position. The general use of it is for taking angles in a vertical plane, comprehended under right lines going from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. But besides the parts above described, there is often added on the face, near the centre, a kind of compartment EF, called a quadrat, or geometrical square, which is a kind of separate instrument, and is particularly useful in altimetry and longimetry, or measuring heights and distances.

Of Cole's Quadrant.

This is a very useful instrument, invented by Mr. Benjamin Cole. It consists of six parts, viz. the staff AB, fig. 2, the quadrantal arch DE; three vanes A, B, C; and their vernier FG. The staff is a bar of wood about two feet long, an inch and a quarter broad, and of a sufficient thickness to prevent it from bending or warping. The quadrantal arch is also of wood, and is divided into degrees and third parts of degrees, to a radius of about nine inches; and to its extremities are fitted two radii, which meet in the centre of the quadrant by a pin, about which it easily moves. The sight-vane A is a thin piece of brass, near two inches in height and one broad, set perpendicularly on the end of the staff A, by means of two screws passing through its foot. In the middle of this vane is drilled a small hole, through which the coincidence or meeting of the horizon and solar spot is to be viewed. The horizontal vane B is about an inch broad, and two inches and a half high, having a slit cut through it of near an inch long, and a quarter of an inch broad; this vane is fixed in the centre-pin of the instrument, in a perpendicular position, by means of two screws passing through its foot, by which its position with respect to the sight-vane is always the same, their angle of inclination being equal to 45 degrees. The shade-vane C is composed of two brass plates. The one which serves as an arm, is about 4½ inches long, and ¾ of an inch broad; being pinned at one end to the upper limb of the quadrant by a screw, about which it has a small motion; the other end lies in the arch, and the lower edge of the arm is directed to the middle of the centre-pin. The other plate, which is properly the vane, is about two inches long, being fixed perpendicularly to the other plate, at about half an inch distance from that end next the arch; this vane may be used either by its shade, or by the solar spot cast by a convex lens placed in it. And because the wood-work is often subject to warp or twist, therefore this vane may be rectified by means of a screw, so that the warping of the instrument may occasion no error in the observation, which is performed in the following manner: set the line G on the vernier against a degree of the upper limb of the quadrant, and turn the screw on the backside of the limb forward or backward, till the hole in the sight-vane, the centre of the glass, and the sunk spot in the horizon-vane, lie in a right line.

Of Collin's or Sutton's Quadrant.

From an inspection of the figure, it will be seen that this quadrant, fig. 3, is a stereographic projection of one quarter of the sphere between the tropics, upon the plane of the ecliptic, the eye being in its north pole; and fitted to the latitude of London. The lines running from right to left, are parallels of altitude; and those crossing them are azimuths. The smaller of the two circles bounding the projection, is one quarter of the tropic of Capricorn; and the greater is a quarter of the tropic of Cancer. The two ecliptics are drawn from a point on the left edge of the quadrant, with the characters of the signs upon them; and the two horizons are drawn from the same point. The limb is divided both in degrees and time; and by having the sun's altitude, the hour of the day may here be found to a minute. The quadrantal arches next the centre contain the calendar of months; and under them, in another arch, is the sun's declination On the projection are placed several of the most remarkable fixed stars between the tropics; and the next below the projection are the quadrant and line of shadows

Of Gunter's Quadrant.

This quadrant is represented at fig. 4, and is so called from its inventor, Edmund Gunter. Besides the apparatus of other quadrants, this has a stereographic projection of the sphere on the plane of the equinoctial; and also a calender of the months, next to the divisions of the limb; by which, besides the common purposes of other quadrants, several useful questions in astronomy, &c. are easily resolved. To find the sun's meridian altitude for any given day

versely the day of the year answering any given meridian altitude. Lay the thread to the day of the month in the scale next the limb; then the degree it cuts in the limb is the sun's meridian altitude. And contrariwise, the thread being set to the meridian altitude, it shows the day of the month.

Of Hadley's Quadrant.

Fig. 5 exhibits this instrument as it is usually constructed. It is properly an octant, and is by far the most complete instrument of the kind ever invented: its utility and correctness have obtained for it the name of "*portable observatory.*" The following are its principal parts: B C, the arc of 45°; A D, the index, moving on a pivot, under the centre of the index-glass, E; which glass is in the exact direction of the index, and stands at right angles upon it. F, the fore horizon-glass, which receives the reflection from the index-glass. G, the back horizon-glass. The former stands parallel with the leg, A C; the latter at right angles to it. K is a pivot, on which three dark glasses, or screens move, so that any one, or more, may be placed between the index-glass and the horizon-glass, to diminish the lustre of the reflected planet. H and I, the vanes, or sights. The arc, B C, is called the limb, or quadrantal arc; what is beyond 0, is the arc of excess: the residue of the arc usually is graduated up as far as 100°.

A large portion of the lower part of the index is open, so as to show the gradations on the arc: the lower edge is chamfered, that it may come close down to them, and is there divided into smaller portions: this scale is called the nonius, and shows the smaller divisions in a more correct and obvious manner than could be done by the quadrantal arc, on which each degree is subdivided into no more than three equal parts, of 20′ each. Now the nonius, being divided into 21 equal parts, shows at what portions of the arc the index cuts the division of 20 minutes; therefore it shows every minute.

The Use of Hadley's Quadrant.

For the Fore-Observation.—Bring the index close to the bottom, so that the middle of the Vernier's scale, or nonius, stand against 0 degrees. Hold the plane of the instrument vertical, with the arch downwards; look through the right-hand hole in the vane, and direct the sight through the transparent part of the horizon-glass, to observe the horizon. If the horizon-line, seen both in the quicksilvered part, and through the transparent part, should coincide, or make one straight line, then is the glass adjusted; but if one of the horizon-lines should stand above the other, slacken the screw in the middle of the lever, backwards or forwards, as there may be occasion, until the lines coincide: fasten the screw in the middle of the lever, and all is ready for use.

To take the sun's altitude.—Fix the screens above the horizon-glass, using either or both of them, according to the strength of the sun's rays, by turning one or both the frames of those glasses close against the plane or face of the instrument; then your face being turned towards the sun, hold the quadrant by the braces, or by either radius, as is found most convenient, so as to be in a vertical position, with the arch downwards. Put the eye close to the right-hand hole in the vane, look at the horizon through the transparent part of the horizon-glass, at the same time sliding the index with the left hand, until the image of the sun, seen in the quicksilvered part, falls in with the edge of the horizon, taking either the upper or the under edge of the solar image. Swing your body gently from side to side; and when the edge of the sun is observed not to cut, but to touch the horizon-line, like a tangent, the observation is made. Then will the degrees on the arch, reckoning from the end next your body, give the altitude of that edge of the sun which was brought to the horizon. If the lower edge was observed, then sixteen minutes, added to the said degrees, gives the altitude of the sun's centre; but if the upper edge was used, the sixteen minutes must be subtracted.

To take the altitude of a star.—Look directly up at the star, through the vane, and transparent part of the glass; the index being close to the button: then will the image of the star, by refraction, be seen in the silvered part, right against the star seen through the other part. Move the index forward, and, as the image descends, let the quadrant descend also, to keep it in the silvered part, till it comes down in a line with the horizon, seen through the transparent part, and the observation is made.

To make an artificial horizon.—Often when the atmosphere is clear above, the horizon is so laden with vapours, as to prevent an observation being taken. In such case, an artificial horizon is to be made thus: fill into any vessel, having a diameter of about three inches, and about half an inch deep, from one to two pounds of quicksilver, on which lay a metal speculum, or a piece of plain glass, whose diameter may be about one-third of an inch less than that of the surface of quicksilver: in this the image of the sun may be seen distinctly. Sling the vessel, so that it may remain level, and take an observation with a stained glass, which will subdue the great brilliancy of the reflection. The observation thus taken, will be as correct as if taken by means of the natural horizon.

Quadrant *of altitude,* is a thin piece of metal, in general applied to the globe, and marked with the degrees, from 0 to 90°: when laid upon the meridian of any place, it shows its latitude, or distance from the equator.

Quadrant *of a circle,* or the fourth part of its circumference, is contained under two radii standing at right angles. The quadrant contains ninety degrees, and is the parent of various lines of the greatest utility in many branches of the mathematics, such as the lines of chords, of sines, of latitude, &c.

QUADRAT, a mathematical instrument, called also a geometrical square, and line of shadows; it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrant.

Quadrat, in printing, a piece of metal cast to fill up the spaces between the words, at the close of paragraphs, and other open places. The quadrats are of different sizes, as m quadrats

n quadrats, &c. which are, respectively, of the dimensions of these letters.

QUADRATIC *equation*, in algebra, that wherein the unknown equality is of two dimensions, or raised to the second power. See ALGEBRA.

QUADRATURE, in geometry, denotes the squaring, or reducing a figure to a square. Thus, the finding of a square, which shall contain just as much surface, or area; as a circle, an ellipsis, a triangle, &c. is the quadrature of a circle, ellipsis, &c.

QUADRATURE, in astronomy, that aspect of the moon when she is 90° distant from the sun; or when she is in a middle point of her orbit, between the points of conjunction and opposition, namely, in the first and third quarters.

QUADRATURE-*lines*, are two lines placed on Gunter's sector: they are marked with Q, and 5, 6, 7, 8, 9, 10: of which Q signifies the side of the square, and the other figures the side of the polygons of 5, 6, 7, &c. sides. S, on the same instrument, stands for the semidiameter of a circle, and 90 for a line equal to 90° in circumference.

QUADRILATERAL, in geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure. The quadrilateral figures are either a parallelogram, trapezium, rectangle, square rhombus, or rhomboides.

QUADRILLE, a game at cards, sometimes called ombre by four; which chiefly differs from ombre by three, in being played by four persons; and having all the forty cards dealt out, to each person at ten each.

QUAKERS, a religious sect who appeared in England about the year 1650. The origin will be best given in their own words: "The beginning of the seventeenth century is known to have been a time of great dissension in England, respecting religion; many pious persons having been dissatisfied with the settlement of the church of England in the reign of queen Elizabeth. Various societies of dissenters had accordingly arisen; some of whom evinced their sincerity by grievous sufferings under the intolerance of those who governed church affairs. But these societies, notwithstanding their honest zeal, seemed to have stopped short in their progress towards a complete reformation; and, degenerating into formality, to have lost their most enlightened members, and still to lament the want of something more instructive and consolatory to the soul, than the most rigorous of their ordinances had ever produced. Thus, dissatisfied and disconsolate, they were ready to follow any teacher, who seemed to be able to direct them to that light of peace of which they felt the need. Many in succession engaged their attention; until finding the insufficiency of them all, they withdrew from the community of every visible church, and dwelt retired, and attentive to the inward state of their own minds."

The quakers have places of worship, where they regularly assemble on the sabbath, though sometimes without vocal prayer, or any religious or practical exhortation. They reject water-baptism and the Lord's supper, have no distinct order of ministers, and are firm advocates for the Arminian system of doctrine. Their internal government is much admired; their own poor are supported without parochial aid, and their industry and sobriety are deserving of imitation. They also reprobate the destructive practice of war, the infamous traffic of slaves, and profess their abhorrence of religious persecution. Refusing to pay tithes, they suffer the loss of their goods and of their liberty, rather than comply with the demand, and their *losses* are emphatically termed by them *sufferings*. As the quakers cannot be made to take an oath in a court of justice, their affirmation is permitted in all civil, but not in criminal cases. Towards the close of the 16th century, the respectable William Penn, who founded Pennsylvania, introduced and established a large and flourishing colony of them in America, where they are now very numerous.

QUALITY, is defined by Mr. Locke, to be the power in a subject of producing any idea in the mind: thus a snow-ball having the power to produce in us the ideas of white, cold, and round, these powers, as they are in the snow-ball, he calls qualities; and as they are sensations, or perceptions, in our understandings, he calls ideas.

QUANTITY, any thing capable of estimation, or mensuration; or which, being compared with another thing of the same kind, may be said to be greater or less than it, equal or unequal to it.

QUANTITY, in grammar, an affection of a syllable, whereby its measure, or the time wherein it is pronounced, is ascertained; or that which determines the syllable to be long or short.

QUANTUM, *valebant*, in like manner is where goods and wares sold are delivered by a tradesman at no certain price, or to be paid for them as much as they are worth in general; and the plaintiff is to aver them to be worth so much.

QUARANTINE, a trial which ships undergo when suspected of having on board persons infested with a pestilential disease. Physicians are occasionally consulted on this subject by government, who regulate this unpleasant restriction on the commerce of the country by their judgment, as to the period of time within which the effects of any infection received by any individual on board, would be shown. The usual quarantine is forty days. This may be ordered by the king, with the advice of the privy-council, at such times, and under such regulations, as he judges proper. Ships ordered on quarantine must repair to the place appointed, and must continue there during the time prescribed, without having any intercourse with the shore, except for necessary provisions, which are conveyed with every possible precaution. When the time is expired, and the goods opened and exposed to the air as directed, if there be no appearance of infection they are admitted to port. Ships infected with the pestilence must proceed to St. Helen's Pool in the Scilly islands, and give notice of their situation to the Custom-house officers, and wait till the king's pleasure be known.

QUARRY, a place under ground, out of which are got marble, free-stone, slate, lime stone, or other matters proper for buildings.

QUARTER, the fourth part of any thing, the fractional expression for which is ¼. Quar-

ter, in weights, is generally used for the fourth part of a hundred weight avoirdupois, or 28lbs.

Used as the name of a dry measure quarter is the fourth part of a ton in weight, or eight bushels.

Quarter, in heraldry, is applied to the parts or members of the first division of a coat that is quartered or divided into four quarters.

Quarter *of a point*, in navigation, is the fourth part of the distance between two cardinal points, which is 2° 48′.

Quarter *of a ship*, is that part of a ship's hold which lies between the steerage-room and the transom.

Quarter-*masters*, or **quarteers**, in a ship of war, are officers whose business it is to rummage, stow, and trim, the ship in the hold; to overlook the steward in his delivery of victuals to the cook, and in pumping or drawing out beer, or the like. They are also to keep their watch duly, in conning the ship, or any other duty.

QUARTERING, in gunnery, is when a piece of ordnance is so traversed that it will shoot on the same line or on the same point of the compass as the ship's quarter bears.

QUARTERS, a name given at sea to the several stations where the officers and crew of a ship of war are posted in action.

QUARTER *sessions*. See **Sessions**.

QUARTZ, a mineral of the flint genus, which is divided into five sub-species: viz. the amethyst, the rock-crystal, milk quartz, common quartz and prase.

QUASSIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 14th order gruinales. The calyx is pentaphyllous; there are five petals; the nectarium is pentaphyllous; there are from two to five seed-cases, standing asunder, and monospermous. There are three species, the amara, simaruba, and excelsa.

This tree is so named from Quassi, a negro slave, who first discovered the nature of its wood. Besides its use in medicine, quassia is often used by brewers to communicate a bitter taste to the beer, instead of hops.

QUEEN, a woman who holds a crown singly. The title of queen is also given by way of courtesy to her that is married to a king, who is called by way of distinction queen-consort.

A queen-consort is inferior to the king, and is really his subject, though, as the king's wife, she has several prerogatives above other women.

QUERCUS, the *oak tree*, a genus of the polyandria order, in the monœcia class of plants, and in the natural method ranking under the 50th order, amentaceæ. The calyx is nearly quinquefid; there is no corolla; the stamina are from five to ten in number. The female calyx is monophyllous, very entire, and scabrous. There is no corrolla; the styles are from two to five; and there is an ovate seed.

The English oak claims precedence as a timber-tree, for its prodigious height and bulk, and superior worth of its wood. The oak is remarkable for its slowness of growth, bulk, and longevity. It has been remarked that the oak has attained to the size only of fourteen inches in diameter, and some to twenty, in the space of four score years.

QUICK, or **quickset hedge**, among gardeners, denotes all live hedges, of whatsoever sort of plants they are composed, to distinguish them from dead hedges; but in a more strict sense of the word, it is restrained to those planted with the hawthorn, or cratægus oxyacantha, under which name these young plants, or sets, are sold by the nursery-gardeners, who raise them for sale.

QUICKSILVER. See **Mercury**.

QUILLS, are the large feathers taken out of the end of the wings of geese, ostriches, crows, &c. They are denominated from the order in which they are fixed in the wing; the second and third quills being the best for writing, as they have the largest and roundest barrels. Crow quills are chiefly used for drawing.

QUILTING, a method of sewing two pieces of silk, linen, or stuff, on each other, with wool or cotton between them; by working them all over in the form of chequer or diamond work, or in flowers.

QUINCE. See **Pyrus**.

QUINCUNX, in Roman antiquity, denotes any thing that consists of five-twelfth parts of another, but particularly of the as.

QUINDECAGON, in geometry, a plan figure with fifteen sides and 15 angles, which, if the sides are all equal, is termed a regular quindecagon, and irregular when otherwise.

The side of a regular quindecagon inscribed in a circle is equal in power to the half-difference between the side of the equilateral triangle, and the side of the pentagon inscribed in the same circle; also the difference of the perpendiculars let fall on both sides, taken together.

QUIRE of paper, a quantity of 24 or 25 sheets.

QUITAM, in law, is where an action is brought, or an information exhibited, against a person, on a penal statute, at the suit of the king and the party or informer, when the penalty for breach of the statute is directed to be divided between them; in that case, the informer prosecutes as well for the king as himself.

QUIT-*claim*, in law, signifies a release of any action that one person has against another It signifies also a quitting a claim or title to lands, &c.

QUIT-*rent*, in law, a small rent that is payable by the tenants of most manors, whereby the tenant goes quit and free from all other services. Anciently this payment was called white-rent, on account that it was paid in silver coin, and to distinguish it from rent corn.

QUOIN, or *Coin*, on board a ship, a wedge fastened on the deck, close to the breech of the carriage of a gun to keep it firm up to the ship's side.

QUOITS, a kind of exercise or game known among the ancients under the name discus.

QUO MINUS, is a writ which issues out of the court of exchequer to the king's farmer or debtor, for debt, trespass, &c. Though this writ was formerly granted only to the king's tenants or debtors, the practice now is become general for the plaintiff to surmise, that by the wrong the defendant does him, he is the less able to satisfy his debt to the king, by which means jurisdiction is given to the court of exchequer to determine the cause. This writ is to take the body of the defendant in like manner as the capias in the common pleas, and the writ of latitat in the king's bench.

QUO WARRANTO, in law, a writ which lies against a person or corporation that usurps any franchise or liberty against the king; as to have a fair, market, or the like, in order to oblige the usurper to shew by what right and title he holds or claims such franchise. This writ also lies for mis-user or non-user of privileges granted. The attorney-general may exhibit a quo-warranto in the crown office against any particular persons, or bodies politic or corporate, who use any franchise or privilege without having a legal grant or prescription for the same; and a judgment obtained upon it is final, as being a writ of right.

R.

R, the seventeenth letter of our alphabet. In the notes of the ancients, R. or RO. signifies Roma; R. C. Romana civitas; R. G. C. rei gerendæ causa; R. F. E. D. recte factum et dictum; R. G. F. regis filius; R. P. res publica, or Romani principes; and R. R. R. F. F. F. res Romana ruet ferro, fame, flamma.

Used as a numeral, R. anciently stood for eighty, and with a dash over it, thus $\bar{R}$, for 80,000; but the Greek r, or ρ, signified 100.

RABBETING, in carpentry, the planing or cutting of channels or grooves in boards. In ship-carpentry, it signifies the letting-in of the planks of the ship into the keel; which, in the rake and run of a ship, is hollowed away, that the planks may join the closer.

RABBIT. See LEPUS.

RACHITIS. See MEDICINE.

RACK, an infernal engine of torture, furnished with pullies and chords; &c. for extorting confession from criminals. This instrument is happily banished from almost every civilized state of the world. The trial by the rack was never known to the law of England.

RADICAL. That which is considered as constituting the distinguishing part of an acid, by its union with the acidifying principle, or oxygen, which is common to all acids. Thus, sulphur is the radical of the sulphuric and sulphurous acids. It is sometimes called the base of the acid, but base is a term of more extensive application.

RADIAL CURVES, are curves of the spiral kind, whose ordinates, if they may be so called, all terminate in the centre of the including circle, appearing like radii of that circle, whence the name.

RADIUS, in geometry, the semidiameter of a circle, or a right line drawn from the centre to the circumference. See CIRCLE, and GEOMETRY.

RADIUS. See ANATOMY.

RAFT, a sort of float, formed by an assemblage of various planks or pieces of timber fastened together side by side, so as to be conveyed more commodiously to any short distance in a harbour or road than if they were separate.

RAFTERS, in building, are pieces of timber, which standing by pairs on the raising piece, meet in an angle at the top, and form the roof of a building.

RAG WORT. See SENECIS.

RAGG, *rowley*, a genus of stones belonging to the siliceous class. It is of a dusky or dark-grey colour, with many small shining crystals, having a granular texture, and acquiring an ochry crust by exposure to the air.

RAILWAY, a species of road or carriage-way, in which the track of the carriage-wheels being laid with bars, or rails, of wood, stone, or metal, the carriage is more easily drawn along this smooth surface than over an ordinary road. On some rail-ways in England, the waggons are drawn by means of a steam engine working in a waggon by itself, the wheels of which are driven by the engine, and acting on a rack laid along the road, impel forward both the engine and the attached waggons: in some instances the wheels of the waggon operate by mere friction, and require not the aid of the rack-work. The engines used for this purpose are of the high pressure kind, which require no condensing apparatus. This application of steam, however, has not yet arrived at such perfection as to obtain general adoption; and the present unprecedented mania for rail-ways over the country, to supersede the excellent inland navigation which has done so much for our commerce, is likely to terminate as all such dreams have hitherto done, viz. in the disappointment and loss of many for the enriching of a few.

RAIN. Mr. Luke Howard, who may be considered as our most accurate scientific meteorologist, is inclined to think, that rain is in almost every instance the result of the *electrical* action of clouds upon each other. This idea is confirmed by observations made in various ways, upon the electrical state of clouds and rain; and it is very probable that a thunder-storm is only a more sudden and sensible display of those energies, which, according to the order observable in the creation in other respects, ought to be incessantly and silently operating for more general and beneficial purposes. See METEOROLOGY.

RAINBOW. See OPTICS.

RAISING-*pieces*, in architecture, are pieces that lie under the beams, and over the posts or puncheons.

RAISINS, grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven. The difference between raisins dried in the sun, and those dried in ovens, is very obvious: the former are sweet and pleasant; but the latter have a latent acidity with the sweetness, that renders them much less agreeable.

RAKE *of a ship*, is all that part of her hull which hangs over both ends of her keel. That which is before is called the fore-rake, or rake-forward; and that part which is at the setting on of the stern-post, is called the rake-aft or afterward.

RALLUS, the *rail*, in ornithology, a genus belonging to the order of grallæ. The beak is thickest at the base, compressed, equal, acute, and somewhat sharp on the back near the

point; the nostrils are oval; the feet have four toes, without any web; and the body is compressed. Mr. Latham, in his Index Ornithologicus, enumerates 24 species, besides some varieties. They are chiefly distinguished by their colour. "These birds (says Buffon) constitute a large family, and their habits are different from those of the other shore-birds which reside on sands and gravel. The rails, on the contrary, inhabit only the slimy margins of pools and rivers, especially low grounds covered with flags and other large marsh-plants.

RAM, in zoology, the male of the sheep kind. See Ovis.

Ram, *battering*, in antiquity, a military engine used to batter and beat down the walls of places besieged.

RAMPANT. See Heraldry.

RAMPART, in fortification, is an elevation of earth, round a place capable of resisting the cannon of an enemy; and formed into bastions, curtains, &c. See Fortification.

RAMPHASTOS, in ornithology, a genus belonging to the order of picæ. The bill is very large, and serrated outwardly. The nostrils are situated behind the base of the beak; and in most of the species the feet are toed, and placed two forwards and two backwards. The tongue is long, narrow, and feathered on the edges. Mr. Latham enumerates 15 different species, of which the toucans are the most remarkable.

RANA, *frog*, a genus of amphibia of the order reptiles; the generic character is, body four-footed, without tail, and naked, or without any integument but the skin.

This genus may be divided into three sections, viz. 1. Frogs, commonly so called, or ranæ, with light active bodies, and which leap when disturbed. 2. Slender-limbed frogs, hylæ, calamitæ, or ranæ arboreæ, viz. such as have light bodies, very slender limbs, and toes terminating in flat, circularly expanded, tips, enabling the animals to adhere at pleasure to the surface even of the smoothest bodies. Several of this division generally reside on trees, adhering by their toes to the lower surfaces of the leaves and branches. 3. Toads, bufones, or such as have large heavy bodies, short thick limbs, and which rather crawl than leap when disturbed.

RANCIDITY. The change which oils undergo by exposure to the air.

The rancidity of oils is probably an effect analogous to the oxidation of metals. It essentially depends on the combination of oxygen with the extractive principle, which is naturally united with the oily principle. This inference is proved by attending to the processes used to counteract or prevent the rancidity of oils.

RANDOM *shot*, in gunnery, is a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly, or point blank. The utmost random of any piece is about ten times as far as the bullet will go point blank. The bullet will go furthest when the piece is mounted to about forty-five degrees above the level range.

RANGE, in gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges.

RANGER, a sworn officer of a forest, appointed by the king's letters-patent, whose business is to walk through his charge to drive back the deer out of the purlieus, &c. and to present all trespasses within his jurisdiction at the next forest-court.

RANGES, in a ship, two pieces of timber that go across from side to side; the one on the forecastle, a little abaft the fore mast; and the other in the beak-head, before the wouldings of the bowsprit.

RANK, in war, is a row of soldiers placed side by side.

Rank, the order or rank assigned a person suitable to his quality or merit.

RANUNCULUS, *crowfoot*, a genus of the polygamia order in the polyandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. There are 59 different species of this genus; six or eight of which claim general esteem as flowery plants for ornamenting the gardens.

RAPE, in law, is where a man has carnal knowledge of a woman by force, and against her will; by 18 Eliz. c. 7, if any person shall unlawfully and carnally know and abuse any woman-child under the age of ten years, whether with her consent or against it, he shall be punished as for a rape. And it is not a sufficient excuse in the ravisher to prove that she is a common strumpet; for she is still under the protection of the law, and may not be forced. Nor is the offence of a rape mitigated by shewing that the woman at last yielded to the violence, if such her consent was forced by fear of death or duress; nor is it any excuse that she consented after the fact.

RAPE is also a name given to a division of a county, and sometimes means the same as a hundred, and at other times signifies a division consisting of several hundreds.

RAPHANUS, *radish*, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The calyx is close: the siliqua torose, or swelling out in knots, subarticulated, and round. There are two melliferous glandules between the shorter stamina and the pistil, and two between the longer stamina and the calyx. There are six species; the sativus, or common garden-radish is best known, and of this there are several varieties.

RAREFACTION, in physics, the act whereby a body is brought to possess more room, or appear under a larger bulk, without the accession of any new matter.

RASH, in medicine, an eruption upon the skin, thrown out in fevers or surfeits.

RAT. See Mus.

RATAFIA, a spirituous liquor, prepared from the kernels, &c. of several kinds of fruit, particularly of cherries and apricots. Ratifia of cherries is prepared by bruising the cherries and putting them into a vessel wherein brandy has been long kept; then adding to them the kernels of cherries, with strawberries, sugar, cinnamon, white pepper, nutmegs, cloves; and to twenty pounds of cherries, ten quarts of brandy. The vessel is left open ten or twelve days, and then stopped close for two months before it is tapped.

RATCH, in clock-work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, and make the lock strike

RATCHETS, in a watch, are the small teeth at the bottom of the fusee or barrel, which stops it in winding up.

RATES, in the navy, the orders or classes into which the ships of war are divided, according to their force and magnitude. The regulation which limits the rates of men of war to the smallest number possible, seems to have been dictated by considerations of political economy, or of the simplicity of the service in the royal dock-yards. The British fleet is accordingly distributed into six rates, exclusive of the inferior vessels that usually attend on naval armaments: as sloops of war, armed-ships, bomb-ketches, fire-ships, and cutters, or schooners commanded by lieutenants.

RATIO, in arithmetic and geometry; is that relation of homogeneous things which determines the quantity of one from the quantity of another, without the intervention of a third.

RATION, in the army, a portion of ammunition, bread, drink, and forage, distributed to each soldier in the army, for his daily subsistence, &c. The horse have rations of hay and oats when they cannot go out to forage. The rations of bread are regulated by weight. The ordinary ration of a foot soldier is a pound and a half of bread per day. The officers have several rations, according to their quality and the number of attendants that they are obliged to keep.

RATIONAL, is applied to integral, fractional, and mixt numbers; Thus we say, rational fraction, rational integer, and rational mixt number.

RATIONALE, a solution, or account of the principles of some opinion, action, hypothesis, phænomenon, or the like.

RATLINES, or, as the seamen call them, RATLINS, those lines which make the ladder-steps to get up the shrouds and futtocks, hence called the ratlins of the shrouds.

RATTLE *snake*. See CROTALUS.

RAVELIN, in fortification, was anciently a flat bastion, placed in the middle of a curtain, but now a detached work, composed only of two faces, which make a saliant angle, without any flanks, and raised before the curtain on the counterscarp of the place. A ravelin is a triangular work resembling the point of a bastion, with the flanks cut off. Its use before a curtain is to cover the opposite flanks of the two next bastions.

RAVEN. See CORVUS.

RAY, a genus of fishes of the class amphibia, and of the order nantes. The generic character is, mouth situated beneath the head, transverse, beset with teeth; spiracles beneath, five on each side the neck; body in most species sub-rhomboidal.

This genus, of which there are 19 species, is distinguished by the remarkable breadth and thinness of the body, the pectoral fins appearing like a continuation of the sides themselves, being covered with the common skin. Those best known to us are the thorn-back, and the skate. As an edible fish, the skate is considered as one of the best of its tribe, and is an established article in the European markets, being found in great plenty in the adjoining seas, where it usually frequents the shores in the manner of flat fish. It breeds in the month of March and April, and deposits its ova from May to September.

RE-ACTION, in physiology, the resistance made by all bodies to the action or impulse of others, that endeavour to change its state whether of motion or rest. See MOTION.

REAGENT. In the experiments of chemical analysis, the component parts of bodies may either be ascertained in quantity as well as quality, by the perfect operations of the laboratory, or their quality alone may be detected by the operations of certain bodies called reagents. Thus the infusion of galls is a reagent, which detects iron by a dark purple precipitate; the prussiate of potash exhibits a blue with the same metal.

REALGAR, in chemistry. Arsenic, mineralized by sulphur, forms two ores, named orpiment and realgar, the chemical distinction of which is not very accurately determined. That which has been named realgar is of a red colour, sometimes inclining to scarlet, sometimes to orange. It occurs massive, disseminated, and crystallized, in oblique, tetrahedral or hexaedral prisms, generally small and translucent, or semitransparent, with a shining lustre. Its fracture is uneven: it is soft and brittle, and has a specific gravity of 3.2, or 3.3. It exhales before the blow-pipe a white arsenical smoke, with an arsenical and sulphurous odour, and gives a blue flame. It consists of arsenic and sulphur in the proportions of 80 of the former, and 20 of the latter.

REASONING, the exercise of the faculty of the mind called reasoning; or it is an act or operation of the mind, deducing some unknown propositions from other previous ones that are evident and known.

REACH, in the sea language, signifies the distance between any two points of land, lying nearly in a right line.

REBATE, or REBATEMENT, in commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer, instead of taking time, advances ready money.

REBELLION, taking up arms traitorously against the king, be it by natural subjects, or by others once subdued.

RECEIPTS, are acknowledgments in writing of having received a sum of money or other value. A receipt is either a voucher for an obligation discharged, or one incurred. Receipts for money above 40*s*. must be on stamps; but on the back of a bill of exchange, or promissory note, which is already stamped, is good without a farther duty. Writing a receipt on a stamp of greater value than the law requires, incurs no penalty, and the receipt is good; but if on a stamp of a lower value, or on unstamped paper, then a receipt is no discharge, and incurs a penalty.

RECEIVER, in pneumatics, a glass vessel for containing the thing on which an experiment in the air-pump is to be made.

RECEIVER, in chemistry, a vessel of earth, glass, &c. for receiving any distilled liquor.

RECEPTACLE, in botany, one of the seven parts of fructification, which, according to Linnæus, is the base which connects or supports the other parts. A proper receptacle obtains different names from the parts of the

fructification which supports and connects. When both flower and fruit are supported by it, it is generally styled the receptacle of the fructification. When the receptacle supports the parts of the flower only, it is called the receptacle of the flower.

RECIPE, in medicine, a prescription or remedy, to be taken by a patient; so called, because always beginning with the word *recipe*, i. e. *take;* which is generally denoted by the abbreviature R.

RECIPROCAL *terms*, among logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

RECITATIVO, or Recitative, in music, a kind of singing, that differs but little from ordinary pronunciation, such as that in which the several parts of the liturgy are rehearsed in cathedrals; or that in which the actors commonly deliver themselves on the theatre at the opera, when they are to express some action or passion, to relate some event, or reveal some design.

RECKONING, or a Ship's Reckoning, in navigation, is that account by which at any time it may be known where the ship is, and on what course or courses she is to steer, in order to gain her port; and that account taken from the log-board is called the dead-reckoning.

RECOGNIZANCE, is an obligation of record, which a man enters into before some court of record, or magistrate duly authorized, with condition to some particular act; as to appear at the assizes or quarter-sessions, to keep the peace, &c.

RECORD. An act committed to writing in any of the king's courts, during the term wherein it is written, is alterable, being no record; but that term once ended, and the act duly enrolled, it is a record, and of that credit which admits of no alteration or proof to the contrary.

RECORDARE facias, a writ directed to the sheriff, to remove a cause out of an inferior court, into the king's-bench or common-pleas.

RECORDER, a person whom the mayor and other magistrates of a city or corporation associate to them, for their better direction in matters of justice, and proceedings in law; on which account this person is generally a counsellor, or other person well skilled in the law.

RECOVERY, in law, is obtaining any thing by judgment or trial at law.

A recovery resembles a fine so far as being an action real or fictitious, and in that lands are recovered against the tenant of the freehold, and an absolute fee-simple is vested in the recoverer; but it is carried on through every stage of proceeding, instead of being compromised like a fine.

RECTANGLE, in geometry, the same with a right-angled parallelogram.

RECTANGLED, Rectangular, or Right-angled, appellations given to figures and solids which have one or more right angles: thus a triangle with one right angle, is termed a rectangled triangle; also parallelograms with right angles, squares, cubes, &c. are rectangular.

RECTIFICATION, the art of setting any thing to rights, and hence to rectify the globes, is to fit them for performing any problem.

Rectification, in geometry, is the finding a right line, equal in length to a curve.

Rectification, in chemistry, is nothing but the repetition of a distillation, or sublimation several times, in order to render the substance purer, finer, and freer from aqueous or earthy parts.

RECTORY, in law, is taken for an entire parish-church, with all its rights, glebes, tithes, and other profits whatsoever.

RECTUM, in anatomy, the third and last of the large intestines.

RECURVIROSTRA, in ornithology, a genus belonging to the order of grallæ. The bill is long, subulated, bent back, sharp and flexible at the point. The feet are webbed, and furnished with three toes forwards and a short one behind. Mr. Latham notes of this genus three species, viz. the avosetta, or the one commonly known, the Americana, and the alba. This last, it is probable, has some affinity to the Americana. The recurvirostra avosetta is about the size of a lapwing in body, but has very long legs. The American avoset is rather larger and longer than the last. The bill is similar, and its colour black; the forehead is dusky white; the head, neck, and upper part of the breast, are of a deep cream-colour; the lower parts of the neck behind white; the back is black, and the under parts from the breast pure white; the wings are partly black, partly white, and partly ash-coloured. The recurvirostra, or scolopax alba, is about 14 inches and a quarter long, its colour white, the inferior coverts of its wings duskish, its bill orange, its legs brown.

RED-BOOK of the exchequer, an ancient record or manuscript volume, in the keeping of the king's remembrancer, containing divers miscellaneous treatises relating to the times before the conquest.

REDEMPTION, in law, a faculty or right of re entering upon lands, &c. that have been sold and assigned, upon reimbursing the purchase-money with legal costs. Bargains wherein the faculty, or, as some call it, the equity, of redemption is reserved, are only a kind of pignorative contracts.

REDOUBT, or Redoute, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach, as also for the lodgings of corps de garde, and to defend passages. In marshy grounds, redoubts are frequently made of stone works, for the security of the neighbourhood: their face consists of from 10 to 15 fathoms, the ditch round them from 8 to 9 feet broad and deep, and their parapets have the same thickness.

REDUCTION *of a figure, design, or draught*, is the making a copy of it either larger or smaller than the original, still preserving the form and proportion. The great use of the proportional compasses is the reduction of figures, &c. whence they are called compasses of reduction. There are various methods of reducing figures, &c. The most easy is by means of the pentagraph, or parallelogram; but this has its defects.

REED. See Arundo.

REEF, a term in navigation. When there is a great gale of wind, they commonly roll up part of the sail below, that by this means it may become the narrower, and not draw so

much wind; which contracting or taking up the sail they call a reef, or reefing the sail; so also when a top-mast is sprung, as they call it, that is, when it is cracked, or almost broken in the cap, they cut off the lower piece that was nearly broken off, and setting the other part, now much shorter, in the step again, they call it a reefed top-mast.

REEL, in the manufactories, a machine serving for the office of reeling. There are various kinds of reels, some very simple, others very complex. Of the former kinds those most in use are, 1. A little reel held in the hand, consisting of three pieces of wood, the largest and longest of which (which does not exceed a foot and a half in length, and one fourth of an inch in diameter) is traversed by two other pieces disposed different ways 2. The common reel, or windlass, which turns upon a pivot, and has four flights traversed by long pins or sticks, whereon the skein to be reeled is put, and which are drawn closer or opened wider, according to the skein.

RE-ENTRY, in law, signifies the resuming or retaking a possession in land lately lost.

REFERENCE, in law, is where a matter is referred by the court of chancery to a master, and by the courts at law to a prothonotary, or secondary, to examine and report to the court. Reference also signifies where a matter in dispute is referred to the decision of an arbitrator.

REFINING, in general, is the art of purifying a thing; including not only the assaying or refining of metals, but likewise the depuration or clarification of liquors. Gold and silver may be refined by several methods, which are all founded on the essential properties of these metals, and acquire different names according to their kinds.

REFLECTING *circle*, an astronomical instrument for measuring angles. It is called reflecting from its property, in common with the Hadley's quadrant (of which it is a modification) of observing one of the objects of the angle to be measured by distinct vision, and the other by reflection of plane mirrors. The first instrument of this kind was invented by Tobias Mayers, in 1770, a celebrated astronomer of Gottingen, who calculated the lunar and solar tables for determining the longitude at sea, for which a reward of 3000*l.* was given by the board of longitude.

REFLECTION *of the rays of light*, in catoptrics, is their return, after approaching so near the surfaces of bodies, as to be repelled, or driven backwards. See **OPTICS**.

REGALIA, in law, the rights and prerogatives of a king; which, according to civilians, are six, viz. 1. The power of judicature. 2. The power of life and death. 3. The power of peace and war. 4. A right to such goods as have no owner, as waifs, estrays, &c. 5. Assessments. And, 6. The coinage of money.

Regalia is also used for the apparatus of a coronation, as the crown, the sceptre with the cross, that with the dove, St. Edward's staff, the globe, and the orb with the cross, four several swords, &c.

REGENT, one who governs a kingdom during the minority or absence of the king. In France, the queen-mother has the regency of the kingdom during the minority of the king, under the title of queen-regent.

REGENT also signifies a professor of arts and sciences in a college, who has a set of pupils under his care; but here regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c.; those of philosophy are rather called professors. The foreign universities are generally composed of doctors, professors, and regents.

REGIMEN, the regulation of diet, and, in a more general sense, of all the non-naturals, with a view to preserve or restore health.

REGIMENT, in war, is a body of men, either horse or foot, commanded by a colonel. Each regiment of foot is divided into companies, but the number of companies is not always alike, though our regiments generally consist of ten companies, one on the right of grenadiers, and another on the left of light troops. Regiments of horse most commonly consist of six troops, but some have nine. Regiments of dragoons, in time of war, are generally composed of eight troops, and in time of peace of six.

REGISTER, a public book in which are entered and recorded memoirs, acts, and minutes, to be had recourse to occasionally for knowing and proving matters of fact.

Of these there are several kinds; as, 1. Registers of deeds in Yorkshire and Middlesex, in which are registered all deeds, conveyances, wills, &c. that affect any lands or tenements in those counties, which are otherwise void against any subsequent purchasers, or mortgagees, &c. but this does not extend to any copyhold estate, nor to leases at a rack rent, or where they do not exceed 21 years. The registered memorials must be ingrossed on parchment, under the hand and seal of some of the grantors or grantees, attested by witnesses who are to prove the signing or sealing of them, and the execution of the deed.

Among dissenters who admit of infant baptism, each minister is supposed to keep a register of the several children baptized by him. But as these are frequently lost, by the succession of new ministers to the same congregation; or at best do not give an account of the date of the births, which may have happened many weeks or months before baptism, it is now almost generally the custom among dissenters of all denominations to register the births of their children at the Library in Red-cross Street, London.

REGISTER is also used for the clerk or keeper of a register. Of these we have several, denominated from the registers they keep; as register of the high court of delegates; register of the arches court of Canterbury; register of the court of admiralty; register of the prerogative court; register of the garter, &c.

REGISTER, in printing, is disposing the forms on the press, so that the lines and pages printed on one side of the sheet fall exactly on those of the other.

REGISTER, among letter-founders, is one of the inner parts of the mould in which the printing-types are cast. Its use is to direct the joining the mould justly together again, after opening it to take out the new-cast letter.

REGLETS, in printing, are thin slips of wood, exactly planed to the size of the body of the letter. The smaller sorts are placed between the lines of poetry; and both those and the larger are used in filling up short pages, in

forming the whites or distances between the lines of titles, and in adjusting the distances of the pages in the chase so as to form register.

REGULAR, denotes any thing that is agreeable to the rules of art: thus we say a regular building, verb, &c. A regular figure in geometry is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides is commonly termed an equilateral triangle or square, as all others with more sides are called regular polygons. All regular figures may be inscribed in a circle. A regular solid, called also a Platonic body, is that terminated on all sides by regular and equal planes, and whose solid angles are all equal.

REGULATOR *of a watch*, the small spring belonging to the balance; serving to adjust its motions, and make it go faster or slower.

REGULUS, in chemistry, an imperfect metallic substance that falls to the bottom of the crucible in the melting of ores, or impure metallic substances.

REGULUS, in astronomy, a star of the first magnitude, in the constellation Leo; called also from its situation, corleonis, or the lion's heart.

REIN-*deer*. See CERVUS.

REJOINDER, in law, is the defendant's answer to the plaintiff's replication or reply.

RELEASE, in law, is an instrument in writing, by which estates, rights, titles, entries, actions, and other things, are extinguished and discharged; and sometimes transferred, abridged, or enlarged; and in general, it signifies one person's giving up or discharging the right he has, or claims to have, against another, or his lands, &c. A release may be either in fact or in law; a release in fact is where it is expressly declared, by the very words, as the act and deed of the party; and a release in law is that which acquits by way of consequence, as where a female creditor takes the debtor to be her husband.

RELEASE, in law. Releases are distinguished into express releases in deed, and those arising by operation of law; and are made of lands and tenements, goods and chattels, or of actions real, personal, and mixed.

RELIEF, a certain sum of money which the tenant holding by knight's service, grand serjeantry, or other tenure, for which homage or legal service is due, and being at full age at the death of his ancestor, formerly paid to his lord at his entrance.

RELIEVO, or RELIEF, in sculpture, &c. is the projecture or standing out of a figure, which arises prominent from the ground or plan on which it is formed: whether that figure be cut with the chissel, moulded, or cast.

There are three kinds or degrees of relievo, viz. alto, basso, and demi-relievo. The alto-relievo, or high relievo, is when the figure is formed after nature, and projects as much as the life. Basso-relievo, bass-relief, or low-relievo, is when the work is raised but a little from the ground, as in medals, and the frontispieces of buildings; and particularly in the histories, festoons, foliages, and other ornaments of friezes. Demi-relievo is when one half of the figure rises from the plan.

RELIGION, is a term of very extensive import, and is used by various portions of the human race to designate things, in themselves diametrically opposed to each other, while each and every one is believed to bear upon the same great object, viz. the mode or manner of expressing the high veneration which the human intellect owes to the Supreme Ruler of the universe. Hence we have the Jewish religion, the Christian religion, the Mahometan religion, the Hindoo religion, the Chinese religion, &c. &c. To tell of all these, with their numerous divisions and subdivisions, would require many volumes; suffice it to say, that wherever religion is professed, it is in the way of acknowledging a belief in a future state, of rewards and punishments according to the deeds done in the body. When this is duly considered, and when it is connected with the fact that there are not two individuals of the human race to be found who entertain precisely the same opinions on matters of faith, what an overwhelming idea seizes the mind of the unutterable variety of state that must exist in the spiritual world, and of the immensity of those heavens which, from the commencement of time, have been every moment receiving fresh accessions of inhabitants, and which will continue to do so throughout eternity itself, from the innumerable worlds that compose the boundless creation! What consummate folly is bigotry!

REMAINDER, in law, is an estate limited in lands, tenements, or rents, to be enjoyed after the expiration of another particular estate. There is this difference between a remainder and a reversion: in case of a reversion, the estate granted, after the limited time, reverts to the grantor or his heirs; but by a remainder it goes to some third person, or a stranger.

REMEMBRANCERS, anciently called clerks of the remembrance, certain officers in the exchequer, whereof three are distinguished by the names of the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of the first fruits.

REMITTER, a term in law, which implies that a person having a right is dispossessed, and then by a bad title, different from his former one, gets possession. He is then said to be remitted to his former title, or to be in by remitter, and cannot be turned out, although he gained his last possession by a bad title.

RENDEZVOUS, in a military sense, the place appointed by the general, where all the troops that compose the army are to meet at the time appointed.

RENT, is a certain profit issuing yearly out of lands and tenements corporeal. There are at common law three kinds of rents; rent service, rent charge, and rent seck. Rent service is where the tenant holds his land of his lord by fealty and certain rent; or by homage, fealty, and certain rent; or by other service and certain rent; and it is called a rent service, because it has some corporal service incident to it, which at least is fealty. Rent charge is so called because the land for payment thereof is charged with a distress. Rent seck is where the land is granted without any clause of distress for the same.

The time for payment of rent, and, consequently, for a demand, is such a convenient time before the sun-setting of the last day, as will be sufficient to have the money counted; but if the tenant meet the lessor on the land at any time of the last day of payment, and tender the rent,

that is sufficient tender, because the money is to be paid indefinitely on that day, and therefore a tender on that day is sufficient.

REPERTORY, a place in which things are orderly disposed so as to be easily found when wanted.

REPETITION, in music, denotes a reiterating or playing over again the same part of a composition, whether it is a whole strain, part of a strain, or double strain, &c.

REPLETION. See MEDICINE.

REPLEVIN, is the writ called replegiare facias by him who has cattle or other goods distrained by another, for any cause, and putting in surety to the sheriff, that upon delivery of the thing distrained, he will prosecute the action against the distrainer.

In this writ or action, both the plaintiff and defendant are called actors; the one, that is, the plaintiff, suing for damages, and the avowant or defendant to have a return of the goods or cattle.

REPLICATION, in logic, the assuming or using the same term twice in the same proposition.

REPLICATION, an exception or answer of the plaintiff in a suit to the defendant's plea; and is also that which the complainant replies to the defendant's answer in chancery, &c.

REPORT, in law, is a public relation of cases judicially argued, debated, resolved, or adjudged, in any of the king's courts of justice, with the causes and reasons of the same, as delivered by the judges.

REPRIEVE, to suspend a prisoner from the execution and proceeding of the law at that time. Every judge who has power to order any execution, has power to reprieve.

REPRISE, or REPRIZE, at sea, is a merchant-ship, which, after its being taken by a corsair, privateer, or other enemy, is retaken by the opposite party.

If a vessel thus retaken has been twenty-four hours in the possession of the enemy, it is deemed a lawful prize; but if it is retaken within that time, it is to be restored to the proprietor, with every thing in it, upon his allowing one-third to the vessel which made the reprise.

REPRODUCTION, is usually understood to mean the restoration of a thing before existing, and since destroyed. It is very well known that trees and plants may be raised from slips and cuttings; and some late observations have shewn, that there are some animals which have the same property. The polype (see POLYPUS) was the first instance we had of this; but we had scarcely time to wonder at the discovery Mr. Trembley had made, when Mr. Bonett discovered the same property in a species of water-worm. Amongst the plants which may be raised from cuttings, there are some which seem to possess this quality in so eminent a degree, that the smallest portion of them will become a complete tree again.

A twig of willow, poplar, or many other trees, being planted in the earth, takes root, and becomes a tree, every piece of which will in the same manner produce other trees. The case is the same with these worms; they are cut to pieces, and these several pieces become perfect animals, and each of these may be again cut into a number of pieces, each of which will in the same manner produce an animal.

The reproduction of several parts of lobsters, crabs, &c. is one of the greatest curiosities in natural history. It seems, indeed, inconsistent with the modern system of generation, which supposes the animal to be wholly formed in the egg; that, in lieu of an organical part of an animal cut off, another should arise perfectly like it: the fact, however, is too well attested to be denied.

If the leg of a lobster be broken off by design at the fourth or fifth articulation, what is thus broken off is always reproduced. But if the fracture be made in the first, second, or third articulation, the reproduction is not so certain. And it is very surprising, that, if the fracture be made at these articulations, at the end of two or three days, all the other articulations are generally found broken off to the fourth, which, it is supposed, is done by the creature itself, to make the reproduction certain.

REPTILIA, in natural history, an order of amphibia, the character of which is, that they breathe through the mouth; have feet, and flat naked ears without auricles. There are five genera; viz.

Draco	Siren
Lacerta	Testudo
Rana.	

REPULSION, in physics, that property in bodies, whereby, if they are placed just beyond the sphere of each other's attraction of cohesion, they mutually fly from each other. Thus, if an oily substance, lighter than water, be placed on the surface thereof, or if a piece of iron be laid upon mercury, the surface of the fluid will be depressed about the body laid on it: this depression is manifestly occasioned by a repelling power in the bodies, which hinders the approach of the fluid towards them. But it is possible, in some cases, to press or force the repelling bodies into the sphere of one another's attraction; and then they will mutually tend towards each other, as when we mix oil and water till they incorporate.

REQUESTS, *Court of*, an ancient court of equity, instituted about the nineteenth year of Henry VII.

RESCRIPT, an answer delivered by an emperor, or pope, when consulted by particular persons, on some difficult question, or point of law, to serve as a decision thereof.

RESERVE, *body of*, or *corps de reserve*, in military affairs, the third or last line of an army, drawn up for battle; so called because they are reserved to sustain the rest, as occasion requires; and not to engage, but in case of necessity.

RESIDENCE, is the continuance of a parson or vicar on his benefice.

RESIDUAL *figure*, in geometry, the figure remaining after subtracting a lesser from a greater.

RESIDUARY *Legatee*, is he to whom the residue of a personal estate is given by will; and such legatee being made executor with others, shall retain against the rest.

RESIN. The name *resin* is used to denote solid inflammable substances, of vegetable origin, soluble in alcohol, usually affording much

soot by their combustion. They are likewise soluble in oils, but not at all in water; and are more or less acted upon by the alkalis.

All the resins appear to be nothing else but volatile oils, rendered concrete by their combination with oxygen. The exposure of these to the open air, and the decomposition of acids applied to them, evidently prove this conclusion.

There are some among the known resins which are very pure, and perfectly soluble in alcohol, such as the balsam of Mecca and of Capivi, turpentines, tacamahaca, elemi: others are less pure, and contain a small portion of extract, which renders them not totally soluble in alcohol; such are mastic, sandarach, guaiacum, labdanum, and dragon's blood.

RESISTANCE, or **Resisting** *force*, in philosophy, denotes, in general, any power which acts in an opposite direction to another, so as to destroy or diminish its effect. Hence the force wherewith bodies, moving in fluid mediums, are impeded or retarded, is the resistance of those fluids.

RESOLUTION, or **Solution**, in mathematics, is an orderly enumeration of several things to be done, to obtain what is required in a problem.

Resolution, in algebra, or *algebraical resolution*, is of two kinds; the one practised in numerical problems, the other in geometrical ones.

Resolution, in chemistry, &c. the reduction of a mixed body into its component parts, or first principles, by a proper analysis. The resolution of bodies is effected by divers operations, as distillation, sublimation, fermentation, precipitation, &c.

RESPIRATION. A function of animals, which consists in the alternate inhalation of a portion of air into an organ called the lungs, and its subsequent exhalation. The venous blood, which enters the lungs from the pulmonary artery, is charged with carbon, to which it owes its dark purple colour. When the atmospherical oxygen is applied to the interior of the air vesicles of the lungs, it combines with the carbon of the blood, forms carbonic acid, which to the amount of from 4.5 to 8 per cent of the bulk of air inspired, is immediately exhaled. It does not appear that any oxygen or azote is absorbed by the lungs in respiration; for the volume of carbonic acid generated, is exactly equal to that of the oxygen which disappears. Now, we know that carbonic acid contains its own volume of oxygen. It is probable that the quantity of carbonic acid, produced in the lungs, varies in different individuals, and in the same individual under different circumstances. The change of the blood, from the purple venous to the bright red arterial, seems owing to the discharge of the carbon. An ordinary sized man consumes about 46 thousand cubic inches of oxygen *per diem*; equivalent to 125 cubic feet of air. He makes about 20 respirations in a minute; or breathes twice, for every seven pulsations. Dr. Prout and Dr. Fyfe found, that after swallowing intoxicating liquors, the quantity of carbonic acid formed in respiration was diminished. The same thing happens under a course of mercury, nitric acid, or vegetable diet.

REST, the continuance of a body in the same place, or its continual application or contiguity to the same parts of the ambient or contiguous bodies; and therefore is opposed to motion. Sir Isaac Newton defines true or absolute rest to be the continuance of a body in the same part of absolute space; and relative rest to be the continuance of a body in the same part of relative space.

RETAINER *of debts*, an executor, among debts of equal degree, may pay himself first, by retaining in his hands, the amount of his debt.

RETARDATION, in physics, the act of diminishing the velocity of a moving body. If bodies of equal bulk, but of different densities, be moved through the same resisting medium, with equal velocity, the medium will act equally on each, so that they will have equal resistances; but their motions will be unequally retarded, in proportion to their densities.

RETICULA, or **Reticule**, in astronomy, a contrivance for the exact measuring the quantity of eclipses.

RETINA, in anatomy, the expansion of the optic nerve on the internal surface of the eye, whereupon the images of objects being painted, are impressed, and by that means conveyed to the common sensory in the brain, where the mind views and contemplates their ideas. See **Optics**.

RETORT, in chemistry, a kind of hollow spherical vessel. See **Laboratory**.

RETRENCHMENT, in the art of war, any kind of work raised to cover a post, and fortify it against the enemy.

RETROGRADATION, or **Retrogression**, the act or effect of a thing moving backwards.

The retrograde motion of the planets is an apparent motion, whereby they seem, to an observer placed on the earth, to move backwards, or contrary to the signs.

REVE, **Reeve**, or **Greve**, the bailiff of a franchise, or manor, thus called, especially in the west of England. Hence shire-reve, sheriff, port-greve, &c.

REVEILLE, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the sentries are to forbear challenging.

REVELATION, is a term used to denote that collection of writings which we call the Bible, that is **the book**, by way of eminence, comprehending a great number of different narratives and compositions, written at different times by different persons, in different languages, and on different subjects. That these books were all composed by those whose names they bear, there is not the least reasonable ground to doubt; they have been always considered as the writings of those persons by the whole Jewish nation, who were most interested in their authenticity, and most likely to know the truth, from the earliest times down to the present: and no proof to the contrary has ever yet been produced.

The Jews were always remarkable for being the faithful guardians of that divine deposit, which they transcribed repeatedly, and compared most carefully with the originals, and of which it is well known, they even numbered the words and letters. Indeed the very Messiahship of Jesus is proved from those very books, which they have preserved.

Taking the whole of the Scriptures together it is an unquestionable truth, that there is no one book extant, in any language, or in any

country, which can in any degree be compared with it for antiquity, for authority, for the importance, the dignity, the variety, and the curiosity of the matter it contains. See INSPIRATION.

REVENUE, PUBLIC, the yearly income appropriated to the expences of government. There are four different sources of public revenue: 1. The income derived from property vested in the public. 2. The emoluments of lucrative prerogatives annexed to the sovereignty. 3. Voluntary contributions from the people. 4. Taxes or imposts, not spontaneously given, but legally exacted. From one or other of these great sources all public revenue must arise.

REVERSION, a sum of money, estate, annuity, or any other kind of property, the possession of which is not to be obtained till after the expiration of a certain period of time, or till some event, as the failure of a life or lives, has happened. The present value of such property depends greatly on the current interest of money, for if money produced only 3 per cent. interest, a person giving 1000*l.* for a reversionary estate relinquishes an annuity of 30*l.*, but if he could make 5 per cent. interest of his money, he gives up an annuity of 50*l.*, and consequently in the latter case he would expect a greater reversion than the former. The true value of a reversion, therefore, is that present sum which if improved at a given rate of interest, would at the period when the reversion comes into possession amount to its then actual value. This, with respect to sums receivable at the end of a certain number of years, is easily found by any correct interest table.

REVIEW, in chancery, is used for a bill where a cause has been heard, and a decree thereon signed; but some error in law appearing upon the decree, or new matter being discovered after it was made, this bill is given for a fresh examination into the merits of the cause.

REVIEW, in war, is the appearance of a army, or part of an army, in order of battle, and their being viewed by the general, that he may know the condition of the troops.

REVIEW, is also the name of one kind of periodical publications, now too much prostituted (under the shelter of anonymous criticism) to the purposes of the malice of rival authors, and the petty artifice of interested booksellers.

REVIVOR, *bill of*, in chancery, is a bill for reviving a cause, where either of the parties dies after the bill and answer, and before the cause is heard; or if heard, before the decree is inrolled; in which case this bill must be brought, praying that the former proceeding may stand revived, and be put upon the same footing as at the time of the abatement.

REVOCATION, in law, signifies the recalling or annulling and making void, some power, grant, deed, &c. made before.

RHAPIS, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the first order palmæ.

RHEA, *Americana*, the American ostrich, in size, is very little inferior to the common one; the bill is sloped, not unlike that of a goose, being flat at the top, and rounded at the end; the eyes are black, and the lids furnished with hairs; the head is rounded, and covered with downy feathers; the neck is two feet eight inches long, and feathered also: from the tip of one wing to that of the other extended, the length is eight feet; it cannot fly, but it runs very swiftly; the legs are stout, and bare of feathers above the knees, and furnished with three toes, all placed forwards, each having a straight and stout claw as in the cassowary; on the heel is a callous knob, serving in the place of a back toe; the general colour of the plumage is dull grey mixed with white, inclining to the latter on the under parts; the tail is very short, and not conspicuous, being entirely covered with long, loose, and floating feathers, having its origin from the lower part of the back and rump, and entirely covering it; the bill and legs are brown.

RHETORIC, in the most extensive sense of the word, denotes the art of composition, or that which enables us to apply language or speech to the best possible advantage. According to etymology, which often affords the most satisfactory explanation of words, it signifies the art of pouring forth a stream of sentiment, and communicating with fluency our feelings and thoughts to others. It is derived from the Greek ῥέω, *to speak*; and this again from ῥέω, *to flow*, or *run like a river.*

Taken in this point of view, rhetoric will comprehend all polite literature, poetry perhaps excepted, the belles-lettres of the French, the pathetic and pleasant of every kind; compositions whose aim and end is not so much to inform or satisfy the understanding, as to move, incline, and persuade, by addressing the imagination, the affections, and, in some measure, sensation itself.

There cannot be a better rule for composition, or one more plain and practical than is laid down by Cicero: "We are first to consider what is to be said; secondly, how; thirdly, in what words; and, lastly, how it is to be ornamented."

RHEUM, a thin serous humour, occasionally oozing out of the glands about the mouth and throat.

RHEUM, *rhubarb*, a genus of the monogynia order, in the enneandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is no calyx; the corolla is sexfid and persistent; and there is one triquetrous seed.

There are seven species, among which the principal is the *R. palmatum*, officinal rhubarb: the root is perennial, thick, of an oval shape, sending off long tapering branches externally it is brown, internally of a deep yellow colour; stem erect, round, hollow, jointed, from six to eight feet in height; root leaves numerous, large, rough, of a roundish figure, deeply cut into lobes, and irregularly pointed segments; on long foot-stalks; stem leaves one at each joint, from a membranaceous sheath, successively smaller upwards; flowers surrounding the branches in numerous clusters forming a kind of spike; corolla of a greenish white colour It is a native of China and Tartary. At the end of six or seven years, when the plant seems to arrive at its most perfect state, one pound of rhubarb may be obtained from every five pounds of the green roots, besides an equal or larger proportion of roots fit for family use.

RHINOCEROS, a genus of quadrupeds of the order belluæ: the generic character is, horn solid, perennial, conical, seated on the nose.

1. Rhinoceros unicornis, single-horned rhinoceros. The rhinoceros is the largest of land animals, the elephant alone excepted. It is of a highly uncouth and awkward form. The back, instead of rising, as in the elephant, sinks in considerably: the head is moderately large and long; the upper lip protrudes or hangs over the lower in the form of a lengthened tip; and, being extremely pliable, answers the end of a small proboscis, and is useful to the animal in catching hold of the shoots of vegetables, &c. and delivering them into the mouth. On the nose is situated a very strong, slightly curved, sharp-pointed horn, which, in the full-grown animal, is sometimes three feet in length, and eighteen inches in circumference at the base.

The rhinoceros is a native of several parts of India, as well as of the islands of Java, Sumatra, &c. This animal falls far short of the elephant in sagacity and docility. It is, however, of a quiet and inoffensive disposition, but very furious and dangerous when provoked or attacked: he is said to run with great swiftness, and, from his strength and impenetrable covering, is capable of rushing with resistless violence through woods and obstacles of every kind; the trees bending like twigs while he passes between them.

2. Rhinoceros bicornis, the two-horned rhinoceros, is found in various parts of Africa, and seems to have been the kind which was known to the ancient Romans, and by them exhibited in their public shows and combats of animals. In size it equals the common or single-horned species; and its habits and manner of feeding are the same; but it differs greatly in the appearance of its skin, which, instead of the vast and regularly marked armour-like folds of the former, has merely a very slight wrinkle across the shoulders, and on the hinder parts with a few fainter wrinkles on the sides, so that, in comparison with the common rhinoceros, it appears almost smooth; the skin, however, is rough or tuberculated, especially in the larger specimens; but what constitutes the specific or principal distinction is, that the nose is furnished with two horns, one of which is smaller than the other, and situated above it, or higher up on the front.

RHINOMACER, in natural history, a genus of insects of the order coleoptera. Antennæ setaceous, seated on the snout; four feelers, growing thicker towards the end, the last joint truncate. There are three species, found in Italy and Sweden.

RHODIUM. See Chemistry.

RHODIOLA, *rose-wort*, a genus of the octandria order, in the diœcia class of plants, and in the natural method ranking under the 13th order, succulentiæ. There are two species, the rosea and the biternata; the first grows naturally in the clefts of the rocks and rugged mountains of Wales, Yorkshire, and Westmorland.

RHOIMBOIDES. See Geometry.

RHOMBOS. See Geometry.

RHUBARB. See Rheum.

RHUMB, in navigation, a vertical circle of any given place, or the intersection of such a circle with the horizon; in which last sense rhumb is the same with a point of the compass.

Rhumb-line, is also used for the line which a ship describes when sailing in the same collateral point of the compass, or oblique to the meridians.

RHUS. See Sumach.

RHYME. See Poetry.

RHYTHMICAL, in music, an epithet applied to the property or quality, in the ancient melopœia and modern melody, by which the cadences, accents, and quantities, are regulated and determined.

RIBBAND, or Ribbon, a narrow sort of silk, chiefly used for head-ornaments, badges of chivalry, &c.

RIBES, the *currant* and *gooseberry-bush*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 36th order, pomaceæ. There are seventeen species, viz. ten of the currant, and seven of the gooseberry; all these shrubs are too well known to need a particular description in this work.

RICINUS, or Palma Christi, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. There are six species, of which the most remarkable is the communis, or common palma christi.

RIDE, in the sea language, is a term variously applied: thus, a ship is said to ride, when her anchors hold her fast, so that she does not drive by the force either of the wind or tide.

RIDERS, in a ship, are large timbers, both in the hold and aloft, bolted on to other timbers to strengthen them, when the ship is discovered to be too slightly built.

RIDING-CLERK, one of the six clerks in chancery, who, in his turn, annually keeps the controlment-books of all grants that pass the great seal that year.

RIFLE, a fire-arm which has the inside of its barrel cut with from three to nine or ten spiral grooves, so as to make it resemble a female screw, varying from a common screw only in this, that its grooves or rifles are less deflected, and approach more to a right line; it being now usual for the grooves with which the best rifled barrels are cut, to take about one whole turn in a length of thirty inches. The number of these grooves differs according to the size of the barrel and fancy of the workman; and their depth and width are not regulated by any invariable rule.

RIGGING *of a ship*, is all her cordage and ropes, belonging to her masts, yards, &c. A ship is said to be well rigged, when all her ropes are of a fit size and proportion: and she is said to be over-rigged, when her ropes are too large, which is of great prejudice to her sailing, and is apt to make her heel.

RIGHT, in geometry, signifies the same with straight: thus, a straight line is called a right one.

Right, in general signification, includes not only a right, for which a writ of right lies, but also any claim or title, either by virtue of a condition, mortgage, or the like, for which no action is given by law, but only an entry.

RING, in astronomy and navigation, an instrument used for taking the sun's altitude, &c. It is usually of brass, about nine inches diameter, suspended by a little swivel, at the

distance of 45° from the point of which is a perforation, which is the centre of a quadrant of 90 degrees divided in the inner concave surface.

RIOT, in law. When three persons or more shall assemble themselves together with an intent mutually to assist one another, against any who shall oppose them in the execution of some enterprize of a private nature, with force or violence against the peace, or to the manifest terror of the people, whether the act intended was of itself lawful or unlawful: if they only meet for such a purpose or intent, though they shall after depart of their own accord without doing any thing, this is an unlawful assembly.

It is enacted, that if a justice find persons riotously assembled, he alone has not only power to arrest the offenders, and bind them to their good behaviour, or imprison them if they do not offer good bail; but he may also authorize others to arrest them, by a bare verbal command, without other warrant; and by force thereof, the persons so commanded may pursue and arrest the offenders in his absence as well as presence. It is also said, that after any riot is over, any one justice may send his warrant to arrest any person who was concerned in it, and that he may send him to gaol till he shall find sureties for his good behaviour.

By the act 1 George II. st. 2, c. 5, every justice, mayor, sheriff, &c. shall upon notice of a riot, or unlawful, tumultuous assembly of twelve persons, proceed to the place, and make proclamation for them to depart, upon the pains of that act, commonly called the riot act. If any person shall wilfully oppose or hurt any person going to make proclamation, and prevent the same, he shall be guilty of felony, without benefit of clergy. If twelve continue together after proclamation, for one hour, it is felony in like manner. And every justice, &c. shall apprehend persons, and if the rioters are killed, the justice, &c. shall not answer for it. A riot though of fewer persons than twelve, to destroy any church, chapel, meeting, or dwelling-house, out-house, &c. is a capital felony: and the hundred shall answer the damages, as in case of robbery.

If two justices go out to quell a riot, may assemble the *posse comitatus*, and every person capable of travelling is, upon being warned, to join them, on pain of imprisonment.

RITE, among divines, denotes the particular manner of celebrating divine service, in a particular country.

RITUAL, a book directing the order and manner to be observed in celebrating religious ceremonies, and performing divine service in a particular church, diocese, order, or the like.

RIVER, a current, or stream of fresh water, flowing in a bed or channel, from its source into the sea. When a stream is not large enough to bear boats, or small vessels laden, it is called a rivulet or brook. The great as well as the middle-sized rivers, proceed either from a confluence of brooks and rivulets, or from lakes; but no river of magnitude flows from one spring, or one lake, but is augmented by the accession of others.

ROACH. See CYPRINUS.

ROAD in navigation, is a place of anchorage at some distance from shore, where vessels usually moor, to wait for a wind or tide proper to carry them into harbour, or to set sail.

ROASTING, in metallurgy, the separation of volatile bodies from those which are more fixed, by the combined action of air and fire; and is generally the first process in the separation of metals from their ores.

ROBBERY, is a felonious taking away of another man's goods from his person, or presence, against his will, putting him in fear, on purpose to steal the same. The value is immaterial.

If a man force another to part with his property, for the sake of preserving his character from the imputation of having been guilty of an unnatural crime, it will amount to a robbery, even though the party was under no apprehension of personal danger. If any thing is snatched suddenly from the head, hand, or person of any one, without any struggle on the part of the owner, or without any evidence of force, or violence being exerted by the thief, it does not amount to robbery. But if any thing be broken or torn in consequence of the sudden seizure, it would be evidence of such force as would constitute a robbery: as where a part of a lady's hair was torn away by snatching a diamond pin from her head, and an ear was torn by pulling off an ear-ring; each of these cases was determined to be a robbery

Highway-robbery differs from robbery only in this, that there is a reward of 40*l*. for the apprehending of the offender, and the horse which the robber rides is forfeited.

ROBINSONIA, a genus of the icosandria monogynia class and order. The cal. is five-toothed; pet. five; berry striated, two-celled; cells one seeded; seeds villose. There is one species, a tree of Guiana.

ROCK, a stony mass, forming a portion of the substance of this globe. Rocks are in general disposed in mountanic ranges; but in some few instances are found existing in immensely larges separate masses. See GEOLOGY.

ROCKET. See PYROTECHNY.

ROD, a land measure of sixteen feet and a half, and is the same with perch and pole.

ROE, the spawn or seed of fish. That of male fishes is usually distinguished by the name of soft-roe, or milt, and that of the female, by hard roe, or spawn.

ROLL, in manufactories, something wound and folded up in a cylindrical form.

Few stuffs are made up in rolls, except ttins, gauses, and crapes, which are apt to break, and take plaits not easy to be got out, if folded otherwise.

ROLL, in law, signifies a schedule or parchment which may be rolled up by the hand into the form of a pipe.

In these schedules of parchment all the pleadings, memorials, and acts of court, are entered and filed by the proper officer: which being done, they become records of the court.

ROLLING *mill*, in mechanics, a machine for working metals into plates, or bars, which are required of an even thickness.

Rolling mills are chiefly used for drawing out iron bars after they have been manufactured into bar iron by the forge hammer; the rollers leave a smoother surface, and make a

bar of more even thickness than the hammer can be made to do.

ROMAN *Catholics*, in church history, a name given to those christians who believe the doctrines, and submit to the discipline of the church of Rome.

ROOD, a quantity of land equal to forty square perches, or the fourth part of an acre.

ROOK, in ornithology. See CORVUS.

ROOT, in mathematics, a quantity considered as the basis or foundation of a higher power; or one which being multiplied into itself any number of times, produces a square, cubic, biquadratic, &c. quantity; called the second, third, fourth, &c. power of the root, or quantity so multiplied into itself.

ROPE, hemp, hair, &c. spun into a thick yarn, and then several strings of this yarn twisted together by means of a wheel. When made very small, it is called a cord, and when very thick, a cable. All the different kinds of this manufacture, from a fishing line, or whipcord, to the cable of a first-rate ship of war, go by the general name of cordage. Ropes are made of every substance that is sufficiently fibrous, flexible, and tenacious, but chiefly of the inner barks of plants.

ROPE *making*, is an art of very great importance; and there are few that better deserve the attention of the intelligent observer. Hardly any art can be carried on without the assistance of the rope-maker. Cordage makes the very sinews and muscles of a ship; and every improvement which can be made in its preparation, either in respect to strength or pliableness, must be of immense service to the mariner, and to the commerce and defence of nations.

ROSA, the *rose*, a genus of the polygynia order, in the icosandria class of plants, and in the natural method ranking under the 35th order, senticosæ. The sorts of roses are very numerous; and the botanists find it very difficult to determine with accuracy which are species and which are varieties.

ROSMARINUS, *rosemary*, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 42d order, verticillatæ. There are two species the officianalis and chilensis.

ROTACEÆ, in botany, the name of the twentieth order in Linnæus's Fragments of a natural method, consisting of plants with one flat, wheel-shaped petal.

ROTATION, in geometry, a term chiefly applied to the circumvolution of any surface round a fixed and immoveable line, which is called the axis of its rotation; and by such rotations it is, that solids are conceived to be generated.

ROTTEN-STONE, a mineral found in Derbyshire, and used by mechanics for all sorts of finer grinding and polishing, and sometimes for cutting of stones. According to Ferber, it is a tripoli mixed with calcareous earth.

ROUND, in a military sense, signifies a walk which some officer, attended with a party of soldiers, takes in a fortified place around the ramparts in the night-time, in order to see that the centries are watchful, and every thing in good order.

RUBRIA. See MADDER.

RUBRIC, in the canon law, signifies a title or article in certain ancient law books; thus called because written, as the titles of the chapters in our ancient bibles are, in red letters. Rubrics also denote the rules and directions given at the beginning, and in the course of the liturgy, for the order and manner in which the several parts of the office are to be performed.

RUBUS, the *bramble*, a genus of the polygamia order, in the icosandria class of plants; and in the natural method ranking under the 35th order, senticosæ. The principal species is the idæus, or common raspberry, which, with its varieties, demands culture in every garden for their fruit; particularly the common red kind, white sort, and twice bearing raspberry; all of which are great bearers; but for the general plantations, we choose principally the common red and the white kind, as being generally the greatest bearers of all.

RUBY. See CORUNDUM.

RUDDER, in navigation, a piece of timber turning on hinges in the stern of the ship, and which, opposing sometimes one side to the water, and sometimes another, turns or directs the vessel this way or that.

RULE, or *Ruler*, an instrument of wood or metal, with several lines delineated on it, of great use in practical mensuration.

Various forms of the sliding rule have from time to time appeared; that which is used by the officers of the excise is certainly good, but it is cumbersome for the pocket. By far the best and most convenient instrument of this kind that we have seen is that lately invented by Mr. Bevan, civil engineer, who has also published a small treatise to accompany the rule. The operative mechanic will find these of immense service in making his calculations; indeed this rule is highly useful in every department of the common business of life.

RULES *of court*, in law, are certain orders made, from time to time, in the courts of law, which attornies are bound to observe, in order to avoid confusion; and both the plaintiff and defendant are at their peril also bound to pay obedience to rules made in court relating to the cause depending between them.

RUM, a species of brandy or vinous spirits distilled from sugar-canes.

RUMEN, in comparative anatomy, the paunch, or first stomach of such animals as chew the cud, thence called ruminant animals.

RUMMAGE, in the sea-language, signifies to clear a ship's hold, or to remove goods from one place of it to another.

RUNDLET, or **RUNLET**, a small vessel containing an uncertain quantity of any liquor; from three to twenty gallons.

RUNIC, a term applied to the language and letters of the ancient Goths, Danes, and other northern nations.

RUNNER, in the sea-language, a rope belonging to the garnet, and to the two bolt-tackles.

RUNNET, or **RENNET**, the acid juice found in the stomachs of calves that have fed on nothing but milk, and are killed before the digestion is perfect.

RUPERT'S *drops*, a sort of glass-drops with long and slender tails, which burst to pieces on the breaking off those tails in any part, said to have been invented by Prince

Rupert, and therefore called after his name. This surprising phenomenon is supposed to rise from hence, that while the glass is in fusion, or in a melted state, the particles of it are in a state of repulsion; but being dropped into cold water, it so condenses the particles in the external parts of their superficies, that they are easily reduced within the power of each other's attraction, and by that means they form a sort of hard case, which keeps confined the before-mentioned particles in their repulsive state; but when this outer-case is broken, by breaking off the tail of the drop, the said confined particles have then a liberty to exert their force, which they do by bursting the body of the drop, and reducing it to a very peculiar form of powder.

RUST, a word signifying the oxide of a metal. Iron, for instance, when exposed to the air, soon becomes tarnished, and gradually changed into a brown or yellow powder, well known by the name of rust.

RUSTIC, in architecture, implies a manner of building in imitation of nature, rather than according to the rules of art.

RUTA, *rue*, a genus of the monogynia order in the decandria class of plants; and in the natural method ranking under the 26th order, multisiliquæ. There are seven species, of which the most remarkable is the hortensis, or common broad-leaved garden rue, which has been long cultivated for medicinal use.

RYANIA, a genus of the polyandria monogynia class and order. The calyx is five-leaved, corolla none; stigmas four; berry suberous, one-celled, many-seeded. There is one species, a tree of Trinidad.

RYE. See SECALE.

S.

S, the eighteenth letter of our alphabet. Used as a numeral, S. anciently denoted seven; in the Italian music, S. signifies solo; and in books of navigation, S. stands for south; S. E. for south-east; S. W. for south-west; S. S. E. for south south east; S. S. W. for south-south-west.

SABBATARIANS, a sect of Christians, chiefly Baptists, who observe the Jewish or Saturday Sabbath, from a persuasion that, it being one of the ten commandments, which they contend are all in their nature moral, was never abrogated by the New Testament.

SABELLIANS, a sect of Christians of the third century, who embraced the opinions of Sabellius, a philosopher of Egypt, who openly taught that there is but one person in the Godhead.

SABLE. See MUSTELA.

SABRE, a kind of sword, or scimetar, with a very broad and heavy blade, thick at the back, and a little falcated, or crooked towards the point. It is generally worn by the heavy cavalry and dragoons.

SACCHARUM, *sugar*, or the *sugar-cane*, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the fourth order, gramina. The calyx is two-valved; the corolla is also bivalved. There are eleven species; among which we shall notice the S. officinarum, common sugar-cane, the root of this plant is jointed, like that of other sorts of cane, or reed; from this root arise four, five, or more shoots, proportionable to the age or strength of the root, eight or ten feet high according to the goodness of the ground; in very good rich soils, canes have been measured nearly twenty feet in height, these are not so much esteemed as those of a middling growth, abounding in juice, and having little of the essential salt.

SACK *of wool*, a quantity of wool containing just twenty-two stones, and every stone fourteen pounds In Scotland, a sack is twenty-four stone, each stone containing sixteen pounds.

SACKBUT, a musical instrument of the wind kind, being a sort of trumpet, though different from the common trumpet both in form and size: it is fit to play a bass, and is contrived to be drawn out, or shortened, according to the tone required, whether grave or acute.

SACKS *of earth*, in fortification, are canvas-bags filled with earth. They are used in making intrenchments in haste, to place on parapets, or the head of the breaches, &c. to repair them, when beaten down.

SACLACTIC ACID. This acid was discovered by Scheele in 1780. After having obtained oxalic acid from sugar, he wished to examine whether the sugar of milk would furnish the same product.

Saclactic acid may be obtained by the following process: Upon one part of gum arabic, or other similar gum, previously put into a retort, pour two parts of nitric acid. Apply a slight heat for a short time, till a little nitrous gas and carbonic acid gas comes over; then allow the mixture to cool. A white powder gradually precipitates, which may easily be separated by filtration. This powder is saclactic acid.

SACRILEGE, is church robbery, or a taking of things out of an holy place, as where a person steals any vessels, ornaments, or goods of the church.

SADDLE, is a seat upon a horse's back, contrived for the conveniency of the rider. The ancient Romans are supposed not to have made use of saddles and stirrups, and it is thought that they did not come into use till the time of Constantine the Great, A D 340.

SAFETY-*lamp*, is a lamp used by those who are employed in coal mines; its construction is such that a miner may move about with it, and even work by its light in the midst of those explosive mixtures which have so often proved fatal when entered with a common lamp, or a candle. This excellent invention belongs to Sir H. Davy, and is thus briefly described by Dr. Ure.

The safety lamp transmits its light, and is fed with air, through a cylinder of iron or copper wire-gauze; and this fine invention has the advantage of requiring no machinery, no philosophical knowledge to direct its use, and is made at a very cheap rate

The apertures in the gauze should not be more than $\frac{1}{20}$ of an inch square. As the fire-damp is not inflamed by ignited wire, the thickness of the wire is not of importance, but wire from $\frac{1}{40}$ to $\frac{1}{60}$ of an inch in diameter is the most convenient.

The parts of the lamp are,

1. The brass cistern which contains the oil, pierced near the centre with a vertical narrow tube, nearly filled with a wire which is recurved above, on the level of the burner, to trim the wick, by acting on the lower end of the wire, with the fingers. It is called the safety-trimmer.
2. The rim, in which the wire-gauze cover is fixed, and which is fastened to the cistern by a moveable screw.
3. An aperture for supplying oil, fitted with a screw or a cork, and which communicates with the bottom of the cistern by a tube; and a central aperture for the wick.
4. The wire gauze cylinder, which should not have less than 625 apertures to the square inch.
5. The second top $\frac{3}{4}$ of an inch above the first, surmounted by a brass or copper plate, to which the ring of suspension is fixed.
6. Four or six thick vertical wires, joining the cistern below with the top plate, and serving as protecting pillars round the cage.

When the wire-gauze safe-lamp is lighted and introduced into an atmosphere gradually mixed with fire-damp, the first effect of the fire-damp is to increase the length and size of the flame. When the inflammable gas forms as much as $\frac{1}{12}$ of the volume of the air, the cylinder becomes filled with a feeble blue flame, but the flame of the wick appears burning brightly within the blue flame, and the light of the wick augments till the fire-damp increases to $\frac{1}{6}$ or $\frac{1}{5}$, when it is lost in the flame of the fire-damp, which in this case fills the cylinder with a pretty strong light. As long as any *explosive* mixture of gas exists in contact with the lamp, so long it will give light, and when it is extinguished, which happens when the foul air constitutes as much as $\frac{1}{3}$ of the volume of the atmosphere, the air is no longer proper for respiration; for though animal life will continue where flame is extinguished, yet it is al [illegible] with suffering. By fixing a coil of platinum wire above the wick, ignition will continue in the metal when the lamp itself is extinguished, and from the ignited wire the wick may be again rekindled, on going into a less inflammable atmosphere.

SAFFRON. See Crocus.

Saffron is cultivated in fields for use, and no where raised with so much success as in England, the English saffron being generally allowed to be greatly superior to any other.

SAGITTA, in astronomy, the *arrow*, or *dart*, a constellation of the northern hemisphere, near the eagle, consisting of five stars, according to Ptolemy and Tycho; but in Mr. Flamsteed's catalogue, of no less than twenty-three.

SAGITTARIUS, the *archer*, in astronomy, the ninth *sign of the zodiac*. See Astronomy.

SAGO, a simple brought from the East Indies, of considerable use in diet as a restorative. It is produced from the pith of a kind of palm which grows in the East Indies, called the cycas circinalis.

SALE *of goods*. If a man agrees for the purchase of goods, he shall pay for them before he carries them away, unless some term of credit is expressly agreed upon.

If a man upon the sale of goods, warrants them to be good, the law annexes to this contract a tacit warranty, that if they be not so, he shall make compensation to the purchaser; such warranty, however, must be on the sale. But if the vender knew the goods to be unsound, and has used any art to disguise them, or if in any respect, they differ from what he represents them to be to the purchaser, he will be answerable for their goodness, though no general warranty will extend to those defects that are obvious to the senses.

SALIENT. See Fortification.

SALIVA. The fluid secreted in the mouth, which flows in considerable quantity during a repast, is known by the name of saliva.

SALIVATION. See Medicine.

SALIX, the *willow*, a genus of the diandria order, in the diœcia class of plants, and in the natural method ranking under the 50th order, amentaceæ. There are 53 species.

SALMO, the *salmon*, in natural history, a genus of fishes of the order abdominales. Generic character: head smooth, compressed; tongue white and cartilaginous; teeth in the jaws and on the tongue; gill-membrane from four to twelve-rayed; body furnished at the hind part with an adipose fin. Gmelin enumerates fifty-five species, and Shaw sixty-two, of which the following are the principal:

S. salar, or the common salmon. This abounds principally in the Northern Seas, which it quits at particular periods, to ascend rivers to a very considerable height, and deposit its spawn in them.

This fish is remarkable for the excellence of its flavour, and its richness, and is a welcome dish at every table. It constitutes, also, an important article of commerce. The principal fishery for salmon, in this island, is at Berwick on the Tweed.

S. fario, or common trout, is found in almost all the European streams, at least such as are cool and clear. Its length, in general, is about fourteen inches.

S. thymallus, or the grayling, is about a foot and a half long, and abounds in the rivers of mountainous countries in Europe and Asia. It resembles the trout in form. In some of the rivers of England, it is found in great perfection.

SALT, *common*. The preparation of that kind of salt which is used for culinary and œconomical purposes, (muriat of soda,) depends upon the well-known fact, that the salt contained in the sea-water, or brine-springs, being a fixed body, will not rise with the vapour of the water. All therefore, that is wanted, is to expose any water containing salt to evaporation. The salt commonly known by the name of bay-salt is obtained from the water of the sea by evaporation. This evaporation is in some places performed by the heat of the sun, the water being let into shallow trenches, in order to expose as large a surface as possible.

In the northern countries, where the heat of the sun is not sufficiently great, artificial fires are employed. In some salt-works these two methods are united; and in England, and

countries where salt-rock is plentiful, that substance is dissolved in salt water, and then evaporated.

SAMBUCUS, *elder*, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 43d order dumosæ. The calyx is quinquepartite; the corolla quinquefid; the berry trispermous. The species are only five.

SAMIELS, the Arabian name of a hot wind, peculiar to the desert of Arabia. It blows over the desert in the months of July and August from the north-west quarter, and sometimes it continues with all its violence to the very gates of Bagdad, but never affects any body within the walls.

SAND, in natural history, a genus of fossils, the characters of which are, that they are found

appear regular, though more or less complete concretions; not to be dissolved or disunited by water, or formed into a coherent mass by means of it, but retaining their figure in it; transparent, vitrifiable by extreme heat, and not dissoluble in, nor effervescing with, acids.

Sand is of great use in the glass manufacture; the white writing sand being employed for making of the white glass, and a coarse greenish-looking sand for the green glass. In agriculture it seems to be the office of sands to make unctuous earths fertile, and fit to support vegetables, &c.

SANDARIC GUM. A resin in yellowish-white tears, possessing a considerable degree of transparency.

SANDIVER, or GLASS-GALL. This is a saline matter, which rises as a scum in the pots or crucibles in which glass is made.

SANHEDRIM, or SANHEDRIN, among the Jews, the great council of the nation, consisting of seventy senators, taken partly from among the priests and levites, and partly out of the inferior judges, who formed what was called the lesser sanhedrim.

SANIDIUM, in natural history, the name of a genus of fossils of the class of the selenitæ, but neither of the rhomboidal nor columnar kinds, nor any other way distinguishable by its external figure, being made up of several plain flat plates.

SANIES, in medicine, a serous putrid matter, issuing from wounds; it differs from pus, which is thicker and white.

SAP. The sap of trees, chemically considered, is a watery mucilaginous liquid, often strongly saccharine, so as to yield a large quantity of sugar, and to furnish a very strong fermented liquor.

SAP, or *Sapp*, in the art of war, is the digging deep under the earth of the glacis, in order to open a covered passage into the moat.

SAP-*colours*, a name given to various expressed juices of a viscid nature, which are inspissated by slow evaporation for the use of painters; as sap-green, gamboge, &c.

SAPPHIRE. See CORUNDUM.

SARCASM, in rhetoric, a keen bitter expression, which has the true point of satire, by which the orator scoffs and insults his enemy: such was that of the Jews to our Saviour, "He saved others, himself he cannot save."

SARCOCOL, in chemistry, a gum resin, supposed to be the product of the penæa sarcocolla. It is brought from Persia and Arabia, in the form of small grains: they have sweet and bitterish taste, and are very soluble in water.

SARDONYX, a precious stone consisting of a mixture of the chalcedony and carnelian, sometimes in stiata, but at other times blended together.

SARMENTOSÆ, the name of the 11th class in Linnæus's Fragments of a Natural Method, consisting of plants which have climbing stems and branches, that, like the vine, attach themselves to the bodies in their neighbourhood for the purpose of support.

SARSAPARILLA, in pharmacy, the root of the rough smilax of Peru, consisting of a

or thicker, flexible, and composed of fibres running their whole length: they have a bitterish but not ungrateful taste, and no smell: and as to their medicinal virtues, they are sudorific and attenuant, and should be given in decoction, or by way of diet-drink.

SASH, a mark of distinction, which in the British service is generally made of crimson silk for the officers, and of crimson mixed with white cotton for the serjeants. It is worn round the waist in most regiments; in some few, particularly in the Highland corps, it is thrown across the shoulder.

SASSAFRAS, the wood of an American tree. See LAURUS.

It is said to be warm, aperient, and corroborant; and frequently employed as an infusion, in the way of tea, is a very pleasant drink: its oil is very fragrant, and possesses most of the virtues of the wood.

SATELLITE. See ASTRONOMY.

SATIN, a glossy kind of silk stuff, the warp of which is very fine, and stands out so as to cover the coarser woof. Some satins are quite plain, others wrought; some flowered with gold or silver, and others striped, &c.

SATIN SPAR. Fibrous limestone; which see.

SATURATION. Some substances unite in all proportions. Such, for example, are acids in general, and some other salts with water; and many of the metals with each other. But there are likewise many substances which cannot be dissolved in a fluid, at a settled temperature, in any quantity beyond a certain proportion. Thus water will dissolve only about one-third of its weight of common salt, and, if more be added, it will remain solid. A fluid, which holds in solution as much of any substance as it can dissolve, is said to be saturated with it. But saturation with one substance does not deprive the fluid of its power of acting on and dissolving some other bodies, and in many cases it increases this power. For example, water saturated with salt will dissolve sugar; and water saturated with carbonic acid will dissolve iron, though without this addition its action on this metal is scarcely perceptible.

SATURN. See ASTRONOMY.

SAW, an instrument which serves to cut into pieces several solid matters: as wood, stone ivory, &c. The best saws are of tem-

pered steel ground bright and smooth; those of iron are only hammer-hardened: hence, the first, besides their being stiffer, are likewise found smoother than the last.

SAWING, dividing timber, &c. by the application of a saw, either by the hand or mill. The mechanism of a sawing-mill may be reduced to three principal things: the first, that the saw be drawn up and down as long as is necessary, by a motion communicated by water or steam to the wheel: the second, that the piece of timber to be cut into boards be advanced by an uniform motion to receive the strokes of the saw; for here the wood is to meet the saw, and not the saw to follow the wood, therefore the motion of the wood and that of the saw ought immediately to depend the one on the other: the third, that when the saw has cut through the whole length of the piece, the machine stops of itself, and remains immoveable.

SCALE, a mathematical instrument, consisting of several lines drawn on wood, brass, silver, &c. and variously divided, according to the purposes it is intended to serve; whence it acquires various denominations, as the plain scale, diagonal scale, plotting scale, Gunter's scale, &c.

SCAMMONY, in the materia medica. See CONVOLVULUS, and GUM RESINS.

SCANDALUM MAGNATUM, is the special name of a statute, and also of a wrong done to any high personage of the land, as prelates, dukes, marquises, earls, barons, and other nobles; and also the chancellor, treasurer, clerk of the privy seal, steward of the house, justice of one bench or other, and other great officers of the realm, by false news, or horrible or false messages, whereby debates and discord, betwixt them and the commons, or any scandal to their persons, might arise. This statute has given name to a writ, granted to recover damages thereupon.

SCAPEMENT, a general term for the manner of communicating the impulse of the wheels to the pendulum of a clock. Common scapements consist of the swing wheel and pallets only.

SCAPULA. See ANATOMY.

SCAPULAR. See ANATOMY.

SCARABÆUS, *beetle*, a genus of insects of the order coleoptera. The generic character is, antennæ or horns clavate, with a fissile tip; legs generally toothed; body thick and compact. This genus is extremely extensive, there being nearly one hundred species.

SCARIFICATION, in surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping instrument.

SCAVENGERS, two officers annually chosen in every parish in London and its suburbs, by the churchwardens, constables, and other inhabitants, to hire persons called rakers, with carts, to clean the streets, and carry away the dirt and filth, with the ashes and dust from every house.

SCENOGRAPHY, in perspective, the perspective representation of a body on a plane; or a description and view of it in all its parts and dimensions, such as it appears to the eye in any oblique view.

SCHISTUS, in mineralogy, a name given to several different kinds of stones, but more especially to some of the argillaceous kind.

SCHOLIUM, a note, annotation, or remark, occasionally made on some passage, or proposition, of an old author. This term is much used in geometry, and other parts of mathematics.

SCIOPTIC, a sphere, or globe of wood, with a circular hole or perforation, wherein a lens is placed. It is so fitted that, like the eye of an animal, it may be turned round every way, to be used in making experiments in a darkened room.

SCIRE FACIAS, is a judicial writ, and properly lies after a year and a day after judgment given; whereby the sheriff is commanded to summon or give notice to the defendant, that he appear and shew cause why the plaintiff should not have execution.

SCIURUS, SQUIRREL, a genus of quadrupeds of the order glires; the generic character is, upper front-teeth cuneated, lower sharp; grinders in the upper jaw five on each side, in the lower four; clavicles in the skeleton; tail (in most species) spreading towards each side. The animals composing this elegant genus are remarkable for the liveliness of their disposition, the celerity of their motions, and the general beauty and neatness of their appearance. They inhabit woods, live entirely on vegetable food, and take up their residence in the hollows of trees, where they prepare their nests.

SCLEROTICA, in anatomy, one of the tunics, or coats, of the eye.

SCOLD. A common scold is a public nuisance to her neighbourhood, for which offence she may be indicted.

SCOLOPAX, in ornithology, a genus belonging to the order of grallæ. The back is cylindrical, obtuse, and longer than the head; the nostrils are linear; the face is covered, and the feet have four toes. There are fifty species, of which the following are the chief:

S. arquata, or the common curlew, is generally about two feet long, and is to be met with in England throughout the year, either on the coasts, or near the mountains. Slugs and worms, which its bill extracts from the ground in the morning and the evening, constitute its inland subsistence; and when on the shores of the sea, it feeds on marine animals. These birds are often observed in large flocks, and are used by many for food. Those killed on the coasts, however, are rank and fishy.

S. rusticola, or the woodcock. These birds are about fourteen inches in length. They are migratory in this country, and supposed to proceed from Sweden.

S. gallinago, or the snipe, weighs about four ounces, is about twelve inches long, and to be found in nearly every country of the world. Its food consists of worms and insects, which it seeks near small streamlets, and in general in wet grounds. It eats also slugs.

S. ægocephalus, or the common godwit, is of the weight of twelve ounces, and ranks in the highest order of delicacies. It is found in almost every country, and in the marshy grounds of Lincolnshire and Cambridgeshire is particularly abundant.

S. calidris, or redshank, is not uncommon in this island, and particularly towards the south.

SCOLOPENDRA, Centipede, a genus of insects of the order aptera; the generic character is, antennæ setaceous; body depressed; legs numerous, equalling the number of segments of the body on each side; feelers two, setaceous. The larger species of the genus scolopendra, found only in the hotter regions of the globe, are insects of a formidable appearance, and possess the power of inflicting severe pain and inflammation by their bite. Of those one of the most conspicuous is the scolopendra morsitans, a native of many parts of Asia, Africa, and South America.

SCOMBER, Mackrel, a genus of fishes of the order thoracici; the generic character is, body oblong, smooth, sometimes carinated by the lateral line; finlets (in most species) above and below, towards the tail. There are 22 species, of which the most remarkable is, the *scomber scomber*, common mackrel. This beautiful fish is a native of the European and American seas, generally appearing at stated seasons, and swarming, in vast shoals, round particular coasts. Its great resort, however, seems to be within the arctic circle, where it resides in innumerable troops; grows to a larger size than elsewhere, and is supposed to find its favourite food, consisting chiefly of marine insects, in far greater plenty than in warmer latitudes. The shape of the mackrel is highly elegant, and it is justly considered as one of the most beautiful of the European species. Its merit as an article of food universally established, and it is one of those fishes which have maintained their reputation through a long succession of ages.

SCORIA, or Dross, is that mass which is produced by melting metals and ores, and when cold is brittle, and not insoluble in water, being properly a kind of glass.

SCORING, the art of forming a score by collecting and properly arranging under each other the several detached parts of any composition.

SCORPÆNA, a genus of fishes of the order thoracici. The generic character is, head large, aculeated, cirrhose, without scales, subcompressed; eye placed near each other; teeth in the jaws, palate, and throat; gill-membrane seven-rayed; body fleshy; dorsal fin single, with the rays of the fore part spiny Nine species.

SCORPIO, in natural history, a genus of insects of the order aptera. Generic character: eight legs, besides two claspers, or hands, seated on the fore-part of the head; eight eyes, three placed on each side of the thorax, and two on the back: two feelers projecting cheliform; the lip is bifid, and the tail long, jointed, and terminated by a sharp, crooked sting; on the under-side, between the breast and abdomen, are two instruments resembling a comb. There are ten species, all of which are armed with a slight pungent sting; and in hot climates some of them are highly dangerous: they prey upon worms, spiders, flies, &c. and even on one another.

SCOTLAND. By 5 Anne, c. 8, the union of England and Scotland was effected, and the twenty-five articles of union agreed to by the parliaments of both nations, were ratified and confirmed as follows; viz. the succession to the monarchy of Great Britain, shall be the same as was before settled with regard to that of England. The united kingdoms shall be represented by one parliament. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed. When England raises 2,000,000*l.* by land-tax, Scotland shall raise 48,000*l.*; the standards of the coin, of weights and measures, shall be reduced to those of England, throughout the united kingdoms. The laws relating to the trade, customs, and the excise, shall be the same in Scotland as in England; but all the other laws of Scotland shall remain in force, though alterable by the parliament of Great Britain; and particularly laws relating to public policy, are alterable at the discretion of parliament; laws relating to private right are not to be altered, but for the evident utility of the people of Scotland. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and forty-five members to sit in the house of commons.

SCRUPLE, a weight equal to the third part of a drachm, or to twenty grains.

SCULPTURE. Sculpture is an art, in which, by means of taking away, or adding to, matter, all sorts of figures are formed, either in clay or wax, wood, marble or other stones, or metal.

The art of sculpture, in its most extensive sense, comprehends not only carving in wood, stone, or marble, but also enchasing, engraving in all its kinds, and casting in bronze, or lead, wax, and plaster of Paris, as well as modelling in clay, wax, or stucco.

The art of sculpture, like its sister, painting, is imitative, not for the gratification of the eye only, but also of the intellect. It is capable of expressing all forms that fall under our inspection, and also of conveying more select expressions of beauty than are to be found, either by ordinary observation, or are generally united in one body, and which are therefore called ideal forms.

Little need be said of the mechanical part of this art, as various chisels, a mallet, compasses, and materials for polishing marble, are all that is required; the essential is seated in the mind, and, as Roubiliac used to say, "the figure is in the substance of the marble, I only extricate it from the enclosure, or pick it out."

SCUTAGE, was anciently a tax imposed on such as held lands, &c. by knight's service, towards furnishing the king's army.

SCUTTLES, in a ship, square holes cut in the deck, big enough to let in the body of a man, serving to let people down into any room below upon occasion, or from one deck to another.

SEA, is frequently used for that vast tract of water encompassing the whole earth; but is more properly a part or division of these waters, and is better defined a lesser assemblage of water, which lies before, and washes the coasts of, some particular countries, from whence it is generally denominated, as the Irish Sea, the Mediterranean Sea, the Arabian Sea, &c.

SEAL, a puncheon or piece of metal, or other matter, usually either round or oval, whereon are engraven the arms, device, &c of some prince, state, community, magistrate, or private person, often with a legend or subscription, the impression whereof in

wax, serves to make acts, instruments, &c. authentic.

SEALER, an officer in chancery, appointed by the lord chancellor or keeper of the great seal, to seal the writs and instruments there made in his presence.

SEAM, or SEME *of corn*, is a measure of eight bushels.

SEAM *of glass*, the quantity of 120 pounds, or 24 stones each five pounds weight. The seam of wood is a horse-load.

SEAMS *of a ship*, are places where her planks meet and join together.

SEARCHER, an officer of the customs, whose business it is to search and examine all ships outward-bound, to see whether they have any prohibited or unaccustomed goods on board.

SEAR *cloth*, or CERE *cloth*, in surgery, a form of external remedy somewhat harder than an unguent, yet softer than an emplaster, though it is frequently used both for the one and the other.

SEA SALT, is merely muriate of soda.

SECALE, *rye*, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the 4th order, gramina.

Rye is commonly sown on poor, dry, limestone, or sandy soils, where wheat will not thrive. By continuing to sow it on such a soil for two or three years, it will at length ripen a month earlier than that which has been raised for years on strong cold ground.

SECANT, in geometry, is a line that cuts another, or divides it into two parts.

In trigonometry, the secant denotes a right line drawn from the centre of a circle, which cutting the circumference, proceeds till it meets with a tangent to the same circle.

SECOND, in geometry, chronology, &c. the sixtieth part of a prime or minute; whether of a degree, or of an hour; it is denoted by two small accents, thus (″).

SECONDARY ROCKS. See MINERALOGY.

SECRETARY, an officer who by his master's orders writes letters, dispatches, and other instruments, which he renders authentic by his signet.

SECRETION, in the animal economy, the separation of some fluid mixed with the blood by means of the glands.

SECTION, in geometry, denotes a side or surface appearing of a body or figure cut by another; or the place where lines, planes, &c. cut each other.

SECTION *of a building*, is the same with its profile; or a delineation of its heights and depths raised on a plane, as if the fabric was cut asunder to discover its inside.

SECTOR, in geometry, is a part of a circle, comprehended between two radii and the arch; or it is a mixed triangle, formed by two radii and the arch of a circle.

SECUNDINES, *after birth*, in anatomy, the several coats or membranes wherein the fœtus is wrapped up in the mother's womb, as the chorion and amnios, with the placenta, &c.

SEED, in botany, the essence of the fruit of every vegetable. Linnæus denominates it to be a deciduous part of the plant, containing the rudiments of the new vegetable, and fertilized by the sprinkling of the male dust.

SEDITION, among civilians, is used for a factious commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of the society.

SEGMENT *of a sphere*, is a part of a sphere terminated by a portion of its surface, and a plane which cuts it off, passing somewhere out of the centre; being more properly called the section of a sphere.

SEIGNIORY, *dominium* in our law, is used for a manor or lordship of a seigneur, or lord of the fee or manor.

SEIGNORAGE, signifies the right, or due belonging to a seigneur, or lord: but it is particularly used for a duty belonging to the prince, for the coining of money, called also coinage; which under our ancient kings was five shillings for every pound of gold brought in the mass to be coined; and a shilling for every pound weight of silver. At present the king claims no seignorage at all.

SEISIN, in law, signifies possession.

SEIZE, SEAZE, or *sease*, in the sea-language, is to make fast, or bind, particularly to fasten two ropes together with rope-yarn.

SEIZURE, in commerce, an arrest of some merchandize, moveable, or other matter, either in consequence of some law, or of some express order of the sovereign.

SELENIUM, (from σεληνη, the moon,) indicating its analogy to Tellurium, is the name given to a substance discovered by Berzelius, having the properties of a metal combined with those of sulphur to a great degree.

Its colour is grey; its lustre bright metallic. It fuses at a few degrees above the boiling point of water; and when slowly cooled, assumes a granular fracture. It unites with the metals.

SELL, in building, is of two kinds, viz. ground-sell, which denotes the lowest piece of timber, in a timber building, and that on which the whole superstructure is raised; and the window-sell, called also window-soil, is the bottom piece in a window-frame.

SEMEN, a substance prepared by nature for the reproduction and conservation of the species both in animals and plants. The peculiar liquid secreted in the testes of males, and destined for the impregnation of females, is known by the name of semen.

SEMI-*circle*, in geometry, half a circle, or that figure comprehended between the diameter of a circle and half the circumference.

SEMI-*colon*, in grammar, one of the points or stops used to distinguish the several members of sentences from each other (;).

SEMI-*diurnal*. Of any of those circles which the sun appears to perform each daily revolution, that portion which is above the horizon is called the diurnal arch, and that which is below the horizon is called the nocturnal arch, the halves of which are called the semi-diurnal and the semi-nocturnal arches.

SENECIO, *groundsel*, a genus belonging to the class of syngenesia, and to the order of polygamia superflua, and in the natural classification ranked under the 49th order, compositæ There are 75 species. Of these, seven are British; the vulgaris, viscosus, sylvaticus, crucifolius, jacobæa, paludosus, and saracenicus.

SENSITIVE PLANT. See MIMOSA.

SENTENCE, in grammar, a period or set

of words comprehending some perfect sense or sentiment of the mind.

SEPIA, the *cuttle-fish*, a genus belonging to the order of vermes mollusca. There are eight brachia interspersed on the interior side, with little round serrated cups, by the contraction of which the animal lays fast hold of any thing. Besides these eight arms, it has two tentacula longer than the arms, and frequently pedunculated. The mouth is situated in the centre of the arms, and is horny and hooked. The eyes are below the tentacula, towards the body of the animal. The body is fleshy, and received into a sheath as far as the breast. Their food are tunnies, sprats, lobsters and other shell-fish. With their arms and trunks they fasten themselves, to resist the motion of the waves. Their beak is like that of a parrot. The females are distinguished by two paps.

The bony scale on the back is that which is sold in the shops, and which, when reduced to fine powder, is reckoned excellent for the teeth, as well for keeping them white as for preserving them. It is also used as pounce. These animals have the power of squirting out a black fluid resembling ink, which is said to be an ingredient used in the composition of Indian ink. They deposit their eggs upon sea-weed, which resemble a bunch of grapes. When first deposited they are white, but when impregnated by the male they become black; they are round, with a little point at the end, and in each of them is inclosed a living cuttle-fish, surrounded with a gelatinous fluid. The flesh is used as food by the Italians.

SEPTUAGINT, the name given to a Greek version of the books of the Old Testament, from its being supposed to be performed by seventy-two Jews, who are usually called the seventy interpreters, because seventy is a round number.

SEPTUM. See ANATOMY.

SEQUESTRATION, is the separating or setting aside of a thing in controversy from the possession of both those who contend for it.

A sequestration is also a kind of execution for debt, especially in the case of a beneficed clerk, of the profits of the benefices, to be paid over to him that had the judgment, till the debt is satisfied.

SERGE, in commerce, a woollen stuff manufactured in a loom, of which there are various kinds, denominated either from their different qualities, or from the places where they are wrought; the most considerable of which is the English serge, which is highly valued abroad, and of which a manufacture had been for some years carried on in France.

SERGEANT, or **SERJEANT AT LAW**, is the highest degree taken in that profession, as that of a doctor is in the civil law. To these serjeants, as men of great learning and experience, one court is set apart for them to plead in by themselves, which is the court of common pleas, where the common law of England is most strictly observed; yet though they have this court to themselves, they are not restrained from pleading in other courts, where the judges (who cannot be elevated to that dignity till they have taken the degree of serjeant at law) call them brothers, and hear them with great respect, next to the king's attorney and solicitor general. These are made by the king's mandate, or writ.

SERGEANT, or *Serjeant*, in war, is an inferior officer in a company of foot, or troop of dragoons, armed with a halberd, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, straighten, and form, ranks, files, &c

SERIES, in general, denotes a continued succession of things in the same order, and having the same relation or connection with each other.

SERIES, *infinite*, is a series consisting of an infinite number of terms, that is, to the end of which it is impossible to come; so that let the series be carried on to any assignable length, or number of terms, it can be carried yet farther, without end or limitation.

SERPENTES, in natural history, an order of the amphibia class, the characteristics of which are, a mouth breathing by the lungs only; body tapering; neck not distinct; jaws dilatable, not articulate; no feet, fins, or ears: motion undulatory. They are cast naked upon the earth, without limbs, exposed to every injury, but frequently armed with a poison the most deadly and horrible, which is contained in tubular fangs resembling teeth, placed without the upper jaw, protruded or retracted at pleasure, and surrounded with a glandular vesicle, by which this fatal fluid is secreted. But lest this tribe should too much encroach upon the limits of other animals, the benevolent Author of Nature has armed only about a fifth in this dreadful manner. The jaws are dilatable and not articulate, and the œsophagus so lax, that they can swallow without mastication, an animal twice or thrice as large as the neck. There are seven genera, viz. the

Achrochordus
Amphisbæna
Anguis
Boa.
Coecilia
Coluber
Crotalus

The distinction between the poisonous and innoxious serpents, is only to be known by an accurate examination of their teeth; those which are poisonous being always tubular, and calculated for the injection of the poisonous fluid, from a peculiar reservoir communicating with the fang on each side the head. These teeth or fangs are situated in the upper jaw: they are frequently accompanied by smaller fangs, seemingly intended to supply the place of the others, if lost by age or accident. The fangs are situated in a peculiar bone, so articulated with the rest of the jaw as to elevate or depress them at the pleasure of the animal in a quiescent state they are recumbent, with their points directed inwards or backwards; but when the animal is inclined to use them as weapons of offence, their position is altered by the peculiar mechanism of the bone in which they are rooted, and they become almost perpendicular.

Serpents in cold and temperate climates conceal themselves during winter, in cavities beneath the surface of the ground, or in any other convenient places of retirement, where they become nearly or wholly in a state of torpidity. Some serpents are viviparous, as the rattle-snake; the viper, &c.: while the innoxious species are oviparous, depositing, as we have observed, their eggs in a kind of chain in any warm and close situation, where they are afterwards hatched

The broad undivided laminæ on the bellies of serpents, are termed scuta, and the smaller or divided ones beneath the tail are called

subcaudal scales, and from these different kinds of laminæ, the Linnæan genera are characterized.

SERPENTINE, a mineral found in amorphous masses, forming strata, and even entire mountains. Its fracture is splintery, sometimes conchoidal; feels soft and almost greasy; generally emits an earthy smell when breathed on. Its colours are various shades of green, yellow, red, grey, brown, and blue: commonly one or two colours form the ground, and one or more appear in spots or veins.

This stone takes its name from its variegated colours, which, in their disposal, very much resemble a serpent's skin.

SERVANT. See Master and Servant.

SERVICE, in law, is a duty which a tenant, on account of his fee, formerly owed to his lord.

SERUM, a thin transparent liquor which makes a considerable part in the mass of blood.

SESSION, in law, denotes a sitting of justices in court upon their commission: as the session of oyer and terminer, &c.

Sessions, *quarter*. The session of the peace is a court of record holden before two or more justices, whereof one is of the quorum, for the execution of the authority given them by the commission of the peace, and certain statutes and acts of parliament.

The justices shall keep their sessions in every quarter of the year at least, and for three days if need be; to wit, in the first week after the feast of St. Michael, in the first week after the Epiphany, in the first week after Easter, and in the first week after St. Thomas, and oftener if need be.

Any two justices, one whereof is of the quorum, by the words of the commission of the peace, may issue their precepts to the sheriff to summon a session for the general execution of their authority; and such session, holden at any time within that quarter of a year, is a general quarter-session. 4. Burn, 181. And such precept should bear teste, or be dated, fifteen days before the return. Nels. Intr. 35.

The sheriff also shall cause a jury to appear at such days and places as the said justices, or such two or more of them as aforsaid, shall appoint.

SET-*off*, is when the defendant acknowledges the justice of the plaintiff's demand on the on hand, but on the other sets up a demand of his own to counterbalance that of the plaintiff, either in the whole, or in part: as if the plaintiff sues for 10*l.* due on a note of hand, the defendant may set off 9*l.* due to himself for merchandize sold to the plaintiff.

SET, or **Sets**, a term used by the farmers and gardeners to express the young plants of the white thorn and other shrubs, with which they use to raise their quick or quickset hedges.

SETON, in surgery, a few horse hairs, small threads, or large packthread drawn through the skin, chiefly the neck, by means of a large needle or probe, with a view to restore or preserve health.

SETTING, in astronomy, the withdrawing of a star or planet, or its sinking below the horizon. Astronomers and poets make three different kinds of setting of the stars, *viz.* the cosmical, achromial, and helical.

Setting, in the sea language. To set the land or the sun, by the compass, is to observe how the land bears on any point of the compass, or on what point of the compass the sun is.

SEWER, a passage or gutter made to carry water into the sea or a river, whereby to preserve the land &c. from inundations and other annoyances. The business of the commissioners of sewers, or their office in particular, is to repair sea-banks and walls, survey rivers, public streams, ditches, &c. and to make orders for that purpose.

SEXAGESIMALS, or **Sexagesimal fractions**, fractions whose denominators proceed in a sexagecuple ratio: that is, a prime or the first minute, $= \frac{1}{60}$; a second $= \frac{1}{3600}$; a third $= \frac{1}{21600}$.

Anciently there were no other than sexagesimas used in astronomy, and they are still retained in many cases, though decimal arithmetic is now generally used in astronomical calculations.

SEXTANT, in mathematics, denotes the sixth part of a circle, or an arch comprehending sixty degrees.

The word sextant is more particularly used for an astronomical instrument made like a quadrant, excepting that its limb only comprehends sixty degrees. The use and application of the sextant is the same with that of the quadrant. See Quadrant.

SEXTON, a church-officer, whose business is to take care of the vessels, vestments, &c. belonging to the church, and to attend the minister, churchwardens, &c. at church.

SEXUAL *system*, in botany, that system of classification which was invented by the immortal Linnæus, professor of physic and botany, at Upsal, in Sweden. It is founded on the parts of fructification, viz. the stamens and pistils; these having been observed with more accuracy since the discovery of the uses for which nature has assigned them, a new set of principles have been derived from them, by means of which the distribution of plants has been brought to a greater decision, and rendered more conformable to true philosophy, in this system, than in any one of those which preceded it.

SHADOW, in optics, a privation or diminution of light, by the interposition of an opake body, or it is a plane where the light is either altogether obstructed, or greatly weakened, by the interposition of some opake body between it and the luminary.

SHAGREEN, or **Chagreen**, in commerce, a kind of grained leather, prepared, as is supposed, of the skin of a species of squalus, or hound-fish, called the shagreen, or shagrain, and much used in covering cases, books, &c.

SHAMMY, or **Chamois Leather**, a kind of leather dressed either in oil or tanned, and much esteemed for its softness, pliancy, and being capable of bearing soap without hurt.

The real shammy is prepared of the skin of the chamois-goat.

The true chamois leather is counterfeited with common goat, kid, and even sheep-skin; the practice of which makes a particular profession, called by the French chamoisure.

SHARK. See Squalus.

SHASTER, or **Shastram**, a sacred book

containing the religion of the Banians; it consists of three tracts; the first of which contains their moral law; the second, the ceremonial; and the third, delivers the peculiar observances for each tribe of Indians.

SHEATHING, in ship-building, a sort of casing or covering nailed all over the outside of a ship's bottom, to protect the planks from the pernicious effects of the worms. It has been customary many years past to sheath the ships of the royal navy, and those of the East India service, with copper. But even vessels thus protected, have been found to return home, after a long voyage, with the copper sheathing extremely injured from the action of the salt water. This led the indefatigable Sir H. Davy, to turn his attention to the subject, and his experiments have been followed with the most complete success. His discovery consists in the simple process of placing contact with the copper, some strips of *positive* metal, zinc for instance, by which the corrosion and foulness from the action of the sea water are prevented.

SHEEP. See Ovis.

SHEERING, or Shearing, in woollen manufacture, is the cutting off with large sheers the too long nap, in order to make the cloth more smooth and even.

SHEKEL, in Jewish antiquity, an ancient coin, worth about 2*s*. 3¼*d*. sterling.

SHELF, among miners, the same with what they otherwise call fast ground, or fast country; being that part of the internal structure of the earth which they find lying even, and in an orderly manner.

SHELL, a substance of a stony hardness, composed of carbonate of lime variously combined with animal gluten, and serving for the coverings and habitations of different animals, mostly of the order of mollusca; allowing of the occasional protrusion of part of their naked body.

Marine shells may be divided, as Mr. Hatchett observes, into two kinds: those that have a porcellaneous aspect, with an enamelled surface, and when broken are often in a slight degree of a fibrous texture; and those that have generally, if not always, a strong epidermis, under which is the shell, principally or entirely composed of the substance called nacre, or mother-of-pearl.

The porcellaneous shells appear to consist of carbonate of lime, cemented by a very small portion of animal gluten. This animal gluten is more abundant in some, however, as in the patellæ.

The mother-of-pearl shells are composed of the same substances. They differ, however, in their structure, which is lamellar, the gluten forming their membranes, regularly alternating with strata of carbonate of lime. In these two the gluten is much more abundant.

Mr. Hatchett made a few experiments on land shells also, which did not exhibit any differences. But the shells of the crustaceous animals he found to contain more or less phosphate of lime, though not equal in quantity to the carbonate, and hence approaching to the nature of bone.

SHERIFF, As keeper of the king's peace, the sheriff is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend and commit to prison all persons who break the peace, or attempt to break it, and may bind any one in a recognizance to keep the king's peace.

SHIELD, an ancient weapon of defence, in the form of a light buckler, borne on the arm to turn off lances, darts, &c.

Shield, in heraldry, the escutcheon or field on which the bearings of coats of arms are placed.

SHIP, a general name for all large vessels, particularly those equipped with three masts and a bowsprit; the masts being composed of a lower-mast, top-mast, and top-gallant-mast; each of these being provided with yards, sails, &c. Ships, in general, are either employed for war or merchandize.

Ships *of war* are vessels properly equipped with artillery, ammunition, and all the necessary martial weapons and instruments for attack or defence. They are distinguished from each other by their several ranks or classes, called rates, as follows: ships of the first rate mount from 100 guns to 110 guns and upwards; second rate, from 90 to 98 guns; third rate, from 64 to 74 guns; fourth rate, from 50 to 60 guns; fifth rate, from 32 to 44 guns; and sixth rate, from 20 to 28 guns. Vessels carrying less than 20 guns, are denominated sloops, cutters, fire-ships, and bombs.

SHIP-BUILDING may be defined, the manner of constructing ships, or the work itself, as distinguished from naval architecture, which may be considered as the theory or art of delineating ships on a plane.

SHIVERS, or Sheevers, in the sea-language, names given to the little rollers or round wheels of pulleys. See Pulley.

SHOE, a covering for the foot, usually made of leather, by the company of cordwainers.

SHORL, in mineralogy, occurs commonly in granite, gneiss, and other similar rocks; often in mass, but very frequently chrystallized.

Shorl, *black*. Colour black. Found in mass, disseminated and crystallized. Crystals three-sided prisms, having their lateral edges truncated. Sometimes terminating in a pyramid. It becomes electric by heat.

SHORT-HAND. See Stenography.

SHOT, a denomination given to all sorts of balls for fire-arms; those for cannon being of iron, and those for guns, pistols, &c. of lead.

SHROWDS, or Shrouds, in a ship, are the great ropes which come down both sides of the masts, and are fastened below to the chains on the ship's side, and aloft to the top of the mast; being parcelled, and served, in order to prevent the mast's galling them.

SIDE, the half of any thing, as an animal, a ship, &c. The sides of an animal are distinguished into the right and left side; but those of a ship, into the starboard and larboard side.

SIDEREAL *day*, is the time in which any star appears to revolve from the meridian to the meridian again; which is 23 hours 56′ 4″ 6‴ of mean solar time; there being 366 sidereal days in a year, or in the time of 365 diurnal revolutions of the sun; that is, exactly, if the equinoctial points were at rest in the heavens.

SIEGE, in the art of war, the encampment of an army before a fortified place, with a design to take it.

SIENITE, or Syenite, a compound gra-

nular aggregated rock, composed of felspar and hornblende, and sometimes quartz and black mica The hornblende is the characteristic ingredient, and distinguishes it perfectly from granite, with which it is often confounded; but the felspar, which is almost always red, and seldom inclines to green, forms the most abundant and essential ingredient of the rock. Some varieties contain a very considerable portion of quartz and mica, but little hornblende. This is particularly the case with the Egyptian varieties, and hence these are often confounded with real granite.

SIEVE, or **Searce**, an instrument serving to separate the fine from the coarse parts of powders, liquors, and the like; or to cleanse pulse from dust, light grains, &c. It is made of a rim of wood, the circle or space whereof is filled with a plexus of silk, tiffany, hair, linen, wire, or even thin slices of wood.

SIGHTS *of a quadrant*, &c. thin pieces of brass, raised perpendicularly on its side, or on the index of a theodolite, circumferentor, &c.

SIGN, in astronomy, a constellation containing a twelfth part of the zodiac, or 30 degrees.

SIGN-MANUAL, in law, is used to signify a bill, or writing, signed by the king's own hand-writing.

SIGNALS, certain alarms or notices used to communicate intelligence to a distant observer.

SIGNATURE, in printing, is a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder, in folding, gathering, and collating them.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bills signed under his majesty's hand.

SILICA. One of the primitive earths, which in consequence of Sir H. Davy's researches on the metallic bases of the alkalis and earths, has been recently regarded as a compound of a peculiar combustible principle with oxygen. If we ignite powdered quartz with three parts of pure potash in a silver crucible, dissolve the fused compound in water, add to the solution a quantity of acid, equivalent to saturate the alkali, and evaporate to dryness, we shall obtain a fine gritty powder, which being well washed with hot water, and ignited, will leave pure silica.

Silica forms one of the constituent parts of most stony bodies; but it exists in greatest abundance in agates, jasper, flints, quartz, and rock crystal: in the latter it exists nearly in a state of purity. Silica is frequently found in nature in the crystallized form, and then it is distinguished by the name of rock crystal. It is most commonly in hexagonal prisms, terminated by hexagonal pyramids.

SILK, in natural history, is the production of different species of caterpillars. The phalæna, or bombyx mori, is most commonly propagated for that purpose in Europe; but the phalena atlas yields a greater quantity. See Bombyx, and Phalæna. A similar substance, indeed, is yielded by the greater number of the tribe of caterpillars. It is found inclosed in two small bags, from which it is protruded in fine threads to serve the insect for a covering during its chrysalis state. The webs of spiders are obviously of the same nature with silk, though their fibres, at least in this country, are finer and weaker.

As soon as the worms have produced their balls, or cocoons, they become an article of trade, for in those countries where silk is cultivated, few persons reel off their cocoons, but sell them to others, who make this operation a separate business. The silk, as formed by the worm, is so very fine, that if each ball, or cocoon, was reeled separately, it would be totally unfit for the purposes of the manufacturer; in the reeling, therefore, the ends of several cocoons are joined and reeled together out of warm water, which, softening their natural gum, makes them stick together, so as to form one strong smooth thread.

The culture of silk varies but little in different countries; it does not require any great degree of skill, or a great capital: and as it is well known that the silk-worm, with proper care, will breed and thrive very well in England, it is not surprising that attempts should have been made to establish the culture of it in this country. The success of Henry the Fourth of France, in extending the culture of silk, which before his time had been confined to a few districts of that kingdom, excited in James the First an active zeal for the introduction of it here. The insurmountable obstacle to raising silk in Great Britain is the climate, which is too cold and wet; and though expedients might be adopted to obviate these inconveniences, they would render the culture of the article, on a large scale, by far too expensive.

In the British settlements in the East Indies, the culture of silk has been long established, particularly in the island of Cossimbwzar and its neighbourhood, in the province of Bengul; and since, about the year 1760, when the company became the rulers of the country, and adopted a new system of trade for the purpose of realizing the surplus revenue, the culture of raw silk has been promoted, and the quantity considerably increased. Of late years, considerable attention has been paid both to the quality of the silk, and to the mode of reeling it, by which it has been very materially improved, so as to rival, in most respects, the produce of Italy.

At no period, perhaps, was the silk trade of Britain known to be in so flourishing a state as it is at present. To a superficial observer, this may appear to arise from the recent reduction of the duty on the raw material; and doubtless this has contributed its share; but we are well satisfied that much also is owing to the very superior quality, and the great beauty of the various articles of home manufacture. As a specimen, we need only refer to the fancy article of an elastic nature, manufactured by Messrs. W. and T. Haimes, of Melbourn, Derbyshire. This article, which we believe was originally meant to imitate a similar article made in France, is used chiefly among the higher orders of society in the form of shawls, turbans, ball-dresses, &c. is now produced by them in a style far exceeding the original. Of this truly ingenious process, some account will be given, under the proper head, in the London Encyclopædia.

SILVER. See Chemistry.

SILVERING, in the arts, consists in covering the surfaces of substances with a thin

coating of silver; either for the purpose of beauty, silver being so much more handsome than the inferior metals; or, on account of its superior wholesomeness, compared with copper, brass, or lead, for culinary purposes, it resisting the corroding power of vinegar and other weak acids.

SILURUS, a genus of fishes of the order abdominales. The generic character is, head large, depressed; mouth wide, bearded by long tentacula; body lengthened, naked; first ray of the pectoral fins, or of the first dorsal fin, toothed backwards. There are 28 species.

SIMIA, ape, a genus of quadrupeds of the order primates. The Linnæan generic character is, front teeth in each jaw four, placed near together; canine teeth solitary, longer than the others, distant from the remaining teeth, or grinders; grinders obtuse. This numerous race may be properly divided into four sections, of which there are about 70 species, viz. 1. Apes, or such as are destitute of a tail. 2. Baboons, or such as have very muscular bodies, and whose tails are commonly short. 4. Monkeys, whose tails are, in general, long: and, lastly sapajous, or monkeys, with what are termed prehensile tails, viz. such as can, at pleasure, be twisted round any object, so as to answer the purpose of an additional hand to the animal,

Of the whole genus, or the monkey tribe in general, it may be observed, that the baboons are commonly of a ferocious and sullen disposition. The larger apes are also of a malignant temper, except the ourang-ontang and the gibbons. The monkeys, properly so called, are very various in their dispositions; some of the smaller species are lively, harmless, and entertaining; while others are as remarkable for the mischievous malignity of their temper, and the capricious uncertainty of their manners.

It may not be improper here to observe, that it is not easy to determine with precision the several species of this extensive genus; since, exclusive of the varieties in point of colour, they are often so nearly allied as to make it difficult to give real distinctive characters.

SIMILAR, in arithmetic and geometry, the same with like. In mathematics, similar parts have the same ratio to their wholes; and if the wholes have the same ratio to the parts, the parts are similar. Similar angles are also equal angles.

SIMILE, or SIMILITUDE, in rhetoric, a comparison of two things, which, though different in other respects, yet agree in some one.

SIMILITUDE, in arithmetic, geometry, &c. denotes the relation of two things similar to each other.

SIMONY, is the corrupt presentation of any one to an ecclesiastical benefice, for money, gift, reward, or benefit.

SIMOOM. A wind or haze was observed by Mr. Bruce, in the course of his travels to discover the sources of the Nile, which is supposed to be in some respects analogous to the sirocco. It is called by him the simoom, and from its effects upon the lungs, we can entertain but little doubt, that it consists chiefly of carbonic acid gas in a very dense state, and perhaps mixed with some other noxious exhalations.

SIMPLE, something not mixed or compounded, in which sense it stands opposed to compound.

SIMPLE, in pharmacy, a general name given to all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy.

SINAPIS, *mustard*, a genus of plants belonging to the class of tetradynamia, and to the order of siliquosa, and in the natural system ranged under the 39th order, siliquosæ. There are 19 species, three of them natives of Britain.

SINE, or *right* SINE *of an arch*, in trigonometry, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end of the arch; being always equal to half the chord of twice the arch.

SINE-*cure*, is where a rector of a parish has a vicar under him endowed and charged with the cure, so that the rector is not obliged either to do duty or residence.

SINKING FUND, a portion of the public revenue set apart to be applied to the reduction or discharge of the public debts. The appropriation of a part of the revenue to this purpose is a measure which had been adopted in other countries, long before any necessity for it existed in England; a provision of this kind having been established in Holland in 1655, and in the Ecclesiastical State in 1685. Both these funds originated in a reduction of the interest payable on the public debts, which was the means afterwards adopted for the establishment of a similar fund in this country.

SIPHON, or SYPHON. See HYDRAULICS.

SIPUNCULUS, or *tube-worm*, a genus of insects of the order of vermes intestina: the generic character is, body round, elongated; mouth cylindrical at the end, and narrower than the body; aperture at the side of the body, and verruciform. There are two species.

SIREN, a genus of amphibia, of the order meantes, of which there are the following species:

1. *Siren lacertina*, or eel-shaped siren: This species stands eminently distinguished in the list of animals by the ambiguity of its characters, which are such as to have induced the great Linnæus to institute for it a new order of amphibia, under the title of meantes; an order however which does not stand among the rest of the amphibia in the Systema Naturæ, but is mentioned in a note at the end of the second part of the first volume of that work.

2. *Siren anguina*, [illegible]ine siren. This singular animal is found in as singular a situation, being an inhabitant of the celebrated and romantic lake called Lake Zirknitz, about six German miles from Labac, in the duchy of Carolina, in Austria.

The species of siren at present to be described is extremely rare; and is found in the spring, and towards the decline of summer, in some particular parts of the above mentioned lake; and commonly measures, when full-grown, from about ten to twelve or thirteen inches in length; the largest specimens being near three quarters of an inch in diameter. It is entirely of a pale rose or flesh-colour, or even nearly white, except the three pair of ramified branchial fins on each side the neck, which are of a bright red or carmine-colour. Its general shape is that of an eel.

SIRIUS, the *dog-star*; a very bright star of the first magnitude, in the mouth of the constellation Canis Major, or the Great Dog. This is the brightest of all the stars in our fir-

mament, and therefore probably, says Dr. Maskelyne, the astronomer royal, the nearest to us of them all.

SIROCCO, a periodical wind which generally blows in Italy and Dalmatia, every year, about Easter. It blows from the south-east by south; it is attended with heat, but not rain; its ordinary period is twenty days, and it usually ceases at sun-set.

SITTA, *nut-hatch*, a genus belonging to the class of aves, and order of picæ. The bill is for the most part straight; on the lower mandible there is a small angle; nostrils small, covered with bristles reflected over them; tongue short, horny at the end, and jagged; toes placed three forward and one backward, the middle toe joined closely at the base to both the outmost: back toe as large as the middle one. There are eleven species.

SIUM, *water parsnip*, a genus of plants belonging to the class of pentandria, and order of digynia, and in the natural system ranging under the 45th order, umbellatæ.

SIZE, is a sort of glue, used by painters, &c. The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is used in many trades.

SKELETON, in anatomy, an assemblage or arrangement of all the bones of a dead animal, dried, cleansed, and disposed in their natural situation, and kept in that order by means of wires, &c.

SKIN. See CUTIS.

SKINNER, one who works in skins.

SKULL, in anatomy, that part of the head which forms its great bony cavity; and in a living subject contains the brain. See ANATOMY.

SKY, the blue expanse of air and atmosphere. The azure colour of the sky Sir Isaac Newton attributes to vapours beginning to condense there, and which have got consistence enough to reflect the most reflexible rays.

SLAB, an outside sappy plank or board sawed off from the sides of a timber-tree; the word is also used for a flat piece of marble.

SLAG, is a term used by the persons employed in working minerals, to express any [illegible] vitrescent, generally coloured, opaque mass, produced by the fusion of any stony or metallic mixture.

SLATE, a well kno[illegible] neat, convenient, and durable material, for the covering of the roofs of buildings. There are great varieties of this substance, and it likewise differs very greatly in its qualities and colours. In some places it is found in thick lamina or flakes, while in others it is thin and light. The colours are white, brown, and blue. It is so durable in some cases, as to have been known to continue sound and good for centuries.

SLAVERY. The law of England abhors, and will not endure, the existence of slavery within this nation. A slave or negro, the moment he lands in England, falls under the protection of the laws, and becomes a free man.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, &c.

SLEEPERS, in a ship, timbers lying before and aft, in the bottom of the ship, as the rung-heads do; the lowermost of them is bolted to the rung-heads, and the uppermost to the fut-

SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity, for the dexterous management of the sling; it is said they bore three kinds of slings, some longer, others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head band, the second for a girdle, and that a third they constantly carried with them in the hand.

SLOE, prunis sylvestris, the English name for the wild plum. See PRUNUS.

SLOOP, a sort of small ship or vessel, usually with one mast, otherwise called shallop. In our navy, sloops are tenders on the men of war, and are usually of about sixty tons, and carry about thirty men.

SLUICE, in hydraulics, a frame of timber, stone, earth, &c. serving to retain and raise the water of the sea, a river, &c. and to let it pass off as occasion may require.

SMELL, *sense of*. The sense of smell is very nearly allied to that of taste, and indeed many of those pleasurable sensations which are usually referred to the taste, as being received during the act of eating and swallowing, really belong to the smell. The organ of smell is a membrane or skin, overspread with nerves, which line the internal cavity of the nostrils, and the surface and cavities of the bones which join the nostrils. This is affected both by the odorous particles which proceed from external substances through the nose, and by those which come from the substances which are eaten; for there is a communication between the nose and the back part of the mouth.

SMELTING, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metalline part from the earthy, stony, and other parts. The art of fusing the ores after roasting, is the principal and most important of metallurgic operations, all the other being preliminary or preparative to this.

SMITHERY, or SMITHING, a manual art, by which an irregular lump of iron is wrought into an intended shape.

SMUT, a disease in corn, which destroys entirely the germ and substance of the grain.

SNAIL. See HELIX, and LIMAX.

SNIPE. See SCOLOPAX.

SOAL-*fish*. See PLEURONECTES.

SNOW. See METEOROLOGY.

SNOWDROP. See GALANTHUS.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here.

SNAPDRAGON, in botany. See ANTIRRHINUM.

SOAP, a composition of caustic fixed alkaline salt and oil, or other grease. It is sometimes hard and dry, sometimes soft and liquid; much used in washing, and other purposes, as well in the arts and manufactures as in domestic purposes.

The materials used in soap-making are, oil of any kind, vegetable or animal; and fixed alkali, either soda or potash. These, (that is, oil and alkali) enter into the composition of every soap, and, besides, lime is essential to give the alkali the requisite degree of causticity common salt is also employed in most of the potash soaps.

The general process for soap-making is on

the whole very simple; and consists, first, in making a caustic, or partly caustic, ley, with the alkali and lime; next, of boiling the ley with the oil till they are perfectly united into a smooth uniform soap; and lastly, of drying the soap till it is become of a proper consistence for use.

SOCAGE, a tenure of lands by or for certain inferior services of husbandry to be performed to the lord of the fee.

SOCIETIES. This word includes a vast circle of associations of men, calculated in some instances to promote the cause of science and literature, and in others intended for the benefit of the individuals and their families who compose them.

Of the former class are the Royal and Antiquarian Societies, and the more recent establishments, under the term of INSTITUTIONS.

SOCINIANS, in church history, a sect of Christians, so called from their founder Faustus Socinus, a native of Sienna, in Italy. He, about the year 1674, began openly to declare against the Roman catholic faith, and taught, 1. That the eternal father was the one only God; that the Word was no more than an expression of the godhead, and had not existed from all eternity; and that Jesus Christ was God no otherwise than by his superiority above all creatures, who were put in subjection to him by the Father. 2. That Jesus Christ was not a mediator between God and men, but sent into the world to serve as a pattern of their conduct; and that he ascended up to heaven only to take a journey thither. 3. That the punishment of hell will last but for a certain time, after which the body and soul will be destroyed. And 4. That it is not lawful for princes to make war.

SODA, a mineral alkali, sometimes found in a native state, as in the lakes of Natron in Egypt, which are dry in the summer season; the water leaving, after evaporation, a bed of soda, or as it is there called, *natron*, of two feet in thickness. A marine plant, called the *salsola soda*, which grows among the cliffs, on the sea coast, seems to be endowed by nature with the property of decomposing the salt water, that is, of separating the muriatic acid from the soda, which latter it absorbs. This plant is collected by the Spaniards, and burnt for the manufacture of *barilla*. Soda procured in a still more impure state by burning the sea weeds on our own shores, particularly in Scotland, from which *kelp* is produced. Few articles are of greater importance to the arts, manufactures, and domestic economy, than soda; it is indispensably necessary for making hard soap, and also forms an excellent substitute for this article. If a weak solution of soda be poured into foul bottles or casks, in which wine has been kept for some time, it will completely dissolve the tartarous crust formed on their inner surface. Boot tops, saddles, or bridles, may with this liquid be effectually cleansed, without affecting the original colour of the leather.

SOLDERS, and SOLDERING. Solders consist merely of simple or mixed metals, by which alone metallic bodies can be firmly united with each other. In this respect it is a general rule, that the solder should always be easier of fusion than the metal intended to be soldered by it; next to this, care must also be taken, that the solder be as far as is possible of the same colour with the metal that is to be soldered.

For the simple solders, each of the metals may be used, according to the nature of that which is to be soldered. For fine steel, copper, and brass work, gold and silver may be employed. In the large way, however, iron is soldered with copper, and copper and brass with tin.

In the operation of soldering, the surfaces of the metal intended to be joined must be made very clean, and applied to each other. It is usual to secure them by a ligature of iron wire, or other similar contrivance. The solder is laid upon the joint, together with sal ammoniac or borax, or common glass, according to the degree of heat intended. These additions defend the metal from oxidation. Glaziers use resin; and pitch is sometimes employed.

The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the size of a crown piece on a table; for, if good, there will arise little bright shining stars in it.

SOLECISM, *soloecismus*, in grammar, a false manner of speaking contrary to the use of language and the rules of grammar, either in respect of declension, conjugation, or syntax.

SOLEN, *razor sheath, or knife-handle shell*, a genus belonging to the class of vermes, and order of testacea. The animal is an ascidia. The shell is bivalve, oblong, and opening at both sides; the hinge has a tooth shaped like an awl, bent back, often double, not inserted into the opposite shell; the rim at the sides somewhat worn away, and has a horny cartilaginous hinge. There are 23 species; three of them, viz. the siliqua, vagina, and ensis, are found on the British coasts, and lurk in the sand near the low water mark in a perpendicular direction.

SOLID. Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth.

SOLIDITY is that property of matter, by which it excludes all other bodies from the place which itself possesses.

SOLO, in music, a term used in pieces consisting of several parts, to mark those that are to perform alon

SOLSTICE. See ASTRONOMY.

SOLUTION, in chemistry, denotes an intimate mixture, or perfect union, of solid bodies with fluids, so as seemingly to form one homogenous liquor.

SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung.

SONG, in music, is applied in general to a single piece of music, whether contrived for the voice or an instrument.

SONG *of birds*. The song of birds has been defined to be a succession of three or four different notes, which are continued without interruption through the same intervals, in a bar of four crotchets, adagio, or while a pendulum swings four seconds.

SOOT, a volatile matter, arising from wood, and other fuel, along with the smoke; or rather, it is the smoke itself, fixed and gathered on the sides of the chimney.

SOPHISM, in logic, &c. an argument which carries much of the appearance of truth, and yet leads into error.

SOREX, *shrew*, a genus of quadrupeds, of the order feræ. The generic character is, front teeth in the upper jaw two, long, bifid; in the lower, two or four, the intermediate ones shorter; canine teeth several on each side; grinders cuspidated.

The genus sorex, of which there are 17 species, in its general appearance bears a great resemblance to the mouse tribe; but the structure, number, and situation of the teeth, prove it to constitute a very different set of animals, which are evidently rather carnivorous than frugivorous.

SOUND is produced by a vibrating motion, excited in a sonorous body by a blow or a shock from another body; and the same motion is communicated by this sonorous body to the air which surrounds it, and transmitted by this fluid to the ear, which is an organ admirably adapted to receive its impression.

The external ear collects and modifies sounds; and by a long channel communicates them to the internal ear: this consists, in the first place, of what is called the drum of the ear, which is a small cavity, closed towards the opening of the ear by a delicate membrane. In the drum are three or four very small bones, furnished with muscles and joints. From the drum are several openings, one of which is to the mouth; the others communicate into the different recesses of the ear. One of these leads into the labyrinth which consists first, of a small irregular cavity, next of three semicircular canals, and lastly, of a winding spiral canal, not unlike some sea shells. All these parts of the cavity are lined with a very delicate membrane, and filled with a watery fluid, which conveys to the portions of the nerve in contact with it, the vibrations received from the membrane which separates the labyrinth from the drum of the ear. The vibrations of the air act upon the drum, and thus set in motion the series of small bones, in the cavity of the drum; these communicate the vibrations to the membrane which separates the drum from the labyrinth, and this (as before mentioned) produces vibrations in the watery fluid, in the several parts of the laybrinth, and conveys to the nervous branches, which line the laybrinth, the vibration originally produced on the drum. The mechanism is complicated, but what we understand must increase our reverential admiration of the skill which produced it.

To illustrate the cause of sound, it is to be observed, 1st, That a motion is necessary in the sonorous body for the production of sound. 2dly, That this motion exists first in the small and insensible parts of the sonorous bodies, and is excited in them by their mutual collision against each other, which produces the tremulous motion so observable in bodies that have a clear sound, as bells, musical chords, &c. 3dly, That this motion is communicated to, or produces a like motion in the air, or such parts of it as are fit to receive and propagate it. Lastly, That this motion must be communicated to those parts that are the proper and immediate instruments of hearing. The sonorous body having made its impression on the contiguous air, that impression is propagated from one particle to another, according to the laws of pneumatics. Sound travels through the air at a mean rate of about 13 miles in an hour.

SOUND, in geography, denotes in general any streight, or inlet, of the sea, between the two headlands.

SOUND-*board*, in an organ, is a reservoir into which the wind, drawn by the bellows, is conducted by a port-vent and hence distributed into the pipes placed over holes in its upper part.

SOUNDING, in navigation, the act of trying the depth of the water, and the quality of the bottom, by a line and plummet, or other artifice.

SOUP, a strong decoction of flesh, or other substances. Portable or dry soup is a kind of cake formed by boiling the gelatinous parts of animal substances till the watery parts are evaporated. This species of soup is chiefly used at sea, and has been found of great advantage.

SOUTHERNWOOD. See ARTEMISIA.

SOW, in the iron-works, the name of the block or lump of metal, they work at once in the iron-furnace.

SPACE, in geometry, denotes the area of any figure or that which fills the interval or distance between the lines that terminate it.

SPACE, in mechanics, the line a moveable body, considered as a point, is conceived to describe by its motion.

SPAN, a measure taken from the space between the thumb's end, and the tip of the little finger, when both are stretched out. The span is estimated at three hand's-breadths, or nine inches.

SPAR, in mineralogy, a name given to those earths which break easily into rhomboidal, cubical, or laminated fragments with polished surfaces.

SPARROW. See FRINGILLA.

SPARROW-HAWK. See FALCO.

SPARTIUM, *broom*, a genus of plants belonging to the class of diadelphia, and order of decandria, and in the natural system arranged under the 32d order, papilionaceæ. The calyx is produced downwards. There are 27 species.

SPATULA, an instrument used by surgeons, and apothecaries.

SPAYING, an operation performed on the females of several kinds of animals, to prevent any further conception, and promote their fattening.

SPEAKER *of the House of Commons*, a member of the house elected by a majority of the votes thereof, to act as chairman or president in putting questions, reading briefs or bills, keeping order, reprimanding the refractory, adjourning the house, &c.

SPECIES, in algebra, the characters or symbols made use of to represent quantities.

SPECIFIC, in medicine, a remedy whose virtue and effect is peculiarly adapted to some certain disease, is adequate thereto, and exerts its whole force immediately thereon.

SPECIFIC-*gravity*. See HYDROSTATICS.

SPECTRUM, in optics. When a ray of light is admitted through a small hole, and received on a white surface, it forms a luminous spot. See OPTICS.

SPECULATIVE, something relating to the theory of some art or science, in contradistinction to practical.

SPECULUM, a *looking-glass* or *mirror*, capable of reflecting the rays of the sun, &c.

SPERMACETI is found in the head of the Physeter macrocephalus, a species of whale; it is obtained in an unctuous mass, from which oil is obtained by expression. Spermaceti is also found in other cetaceous fishes, and in other parts of the body, mixed with the oil. It is a fine white substance of a crystalized texture, very brittle, and has little taste or smell. It crystalizes in the form of shining silvery plates.

SPHERE, is a solid contained under one uniform round surface, such as would be formed by the revolution of a circle about a diameter thereof as an axis.

Sphere, in astronomy, that concave orb, or expanse, which invests our globe, and in which the heavenly bodies appear to be fixed, and at an equal distance from the eye.

SPHERICS, the doctrine of the sphere, particularly of the several circles described on its surface, with the method of projecting the same on a plane.

SPHEROID, a solid body approaching to the figure of a sphere, though not exactly round, but having one of its diameters longer than the other.

SPHINX, the hawk moth, a genus of insects of the order lepidoptera. The generic character is, antennæ thickest in the middle, subprismatic, and attenuated at each extremity; wings deflected; flight strong, and commonly in the evening or morning.

SPICA VIRGINIS, a star of the first magnitude, in the constellation Virgo.

SPIDER. See Aranea.

SPIGELIA, *worm-grass*, a genus of plants belonging to the class of pentandria and order of monogynia; and in the natural system arranged under the 47th order, stellatæ.

SPIKING *up the ordnance*, a sea-phrase, used for fastening a quoin with spikes to the deck, close to the breech of the carriages of great guns, that they may keep close and firm to the ship's sides, and not get loose when the ship rolls, and by that means endanger the breaking out of a butt-head of a plank.

SPINACIA, *spinach*, a genus of plants belonging to the class of diœcia, and to the order of pentandria; and in the natural system arranged under the 12th order, holoraceæ.

SPINET, or Spinnet, a musical instrument ranked in the second or third place among harmonious instruments.

SPINNING, the act of reducing silk, flax, hemp, hair, wool, or other matter, into thread. Spinning is either performed on the wheel, or with a distaff and spindle, or with other machines proper for the several kinds of working.

SPINSTER, in law, an addition usually given to all unmarried women from a viscount's daughter downwards.

SPIRACULA, in entomology, holes or pores on each side of every segment of the abdomen, through which insects breathe.

SPIRAL, in geometry, a curve line of the circular kind, which, in its progress, recedes, from its centre.

SPLICING, in the sea language, is the untwisting the ends of two cables or ropes, and working the several strands into one another by a fid, so that they become as strong as if they were but one rope.

SPLINTER, a small shiver of wood, or the like. The splinters of fractured bones, if loose, are to be carefully removed, otherwise replaced.

SPONDYLUS, a genus of vermes testacea. The generic is, animal a tethys; shell hard, solid, with unequal valves; one of the valves convex, the other rather flat: hinge with two curved teeth, separated by a small hollow There are four species.

SPONGIA, *sponge*, in natural history; a genus of animals belonging to the class of vermes, and order of zoophyta. It is fixed, flexible, and very torpid, growing in a variety of forms, composed either of reticulated fibres, or masses of small spines interwoven together, and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and throws out the water.

Fifty species have already been discovered, of which 10 belong to the British coasts.

SPONTANEOUS Combustion. It is now a well authenticated fact that many vegetable substances, highly dried and heaped together, will heat, scorch, and at last burst into flame. Of these, the most remarkable is a mixture of the expressed oil of the farinaceous seeds, as rape or linseed oil, with almost any dry vegetable fibre, such as hemp, cotton, matting, &c. and still more so, if also united with lamp black, or any other carbonaceous substance. These mixtures, if kept for a time undisturbed, in close bundles, and in a warm temperature, even in small quantities, will often heat, and burn with a smothered fire for some hours; and if air be admitted freely, will then burst into flame. To this may be attributed several accidental conflagrations in storehouses, and places where quantities of these substances are kept.

Several cases of death, from spontaneous combustion of the body, are on record. The appearance resemble those which would be produced by phosphuretted hydrogen.

SPRAT. See Clupea.

SPRING, in natural history, a fountain or source of water, rising out of the ground.

Spring, in mechanics, denotes a thin piece of tempered steel, or rather elastic substance, which, being wound up, serves to put several machines in motion by its elasticity, or endeavour to unbend itself: such is the spring of a clock, watch, &c.

SPRINGING *of a mast*, in the sea language, is when it cracks, but is not broken in any part of it: as the partners, hounds, &c.

SPRUCE-*beer*, a cheap and wholesome liquor, which is thus made: Take of water 16 gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the cold part, which should be previously put into a barrel, or other vessel; then add sixteen pounds of treacle or molasses, with a few table-spoonful of the essence of spruce, stirring the whole well together; add half a pint of yeast, and keep it in a temperate situation, with the bung-hole open, for two days, till the fermentation is abated. Then close it up, or bottle it off, and it will be fit for being drunk in a few days afterwards.

SPUNGING, in gunnery, the cleaning a gun's inside with a sponge, in order to prevent any sparks of fire from remaining in her, which would endanger the life of him who should load her again.

SPUR, a piece of metal, consisting of two

rowel in form of a star, advancing out behind, to prick the horse.

SPY, a person hired to watch the actions, motions, &c. of another; particularly of what passes in a camp. When a spy is discovered, he is hanged immediately.

SQUADRON, in military affairs, denotes a body of horse whose number of men is not fixed; but is usually from one to two hundred. In naval affairs a squadron either implies a detachment of ships employed in any particular expedition, or one-third part of a naval armament.

SQUALUS, the *shark*, in natural history, a genus of fishes of the order cartilaginei. Generic character: mouth under the fore part of the head, with teeth disposed in rows, and partly moveable and partly fixed; generally five spiracles, at the sides of the neck, of a semilunar shape; body, oblong, rather cylindric and rough, with tender prickles. These animals are never found in rivers or lakes, inhabiting only the sea, and carrying terror and destruction wherever they appear. They grow, in some species, to the weight of three or four thousand pounds. They occasionally emit a phosphoric illumination, visible by night. They produce their young alive, several at a birth, but every one inclosed in a transparent hornlike substance, lengthened at the extremity into a thread, which attaches to fixed substances, such as rocks or weeds. Some appear to live on vegetables chiefly, but the greater number are rapacious of animal substances in the extreme. They seize, indeed, whatever they find, with the most violent avidity, following in the wakes of ships, for the sake of nearly every thing thrown from them, and are fatal to those mariners who slip from their hold on the rigging into the sea, in which case the sharks are seen to tear them to pieces, with all the violence of competition.

SQUARE. See GEOMETRY.

SQUARE *number*, the product of a number multiplied into itself.

SQUARE, *in the military art*, a particular formation into which troops are thrown on critical occasions: particularly to resist the charge of cavalry.

SQUARE, *solid*, is a body of foot, where both ranks and files are equal. It was formerly held in great esteem; but when the prince of Nassau introduced the hollow square, this was soon neglected.

SQUIRREL. See SCIURUS.

STAG. See CERVUS.

STAG BEETLE. See LUCANUS.

STALACTITES. These are found suspended from vaults, being formed by the oozing of water charged with calcareous particles, and gradually evaporating, leaving those particles behind.

STALK. See BOTANY.

STAMINA. See BOTANY.

STAMINA, in the animal body, are defined to be those simple original parts, which existed first in the embryo. See PHYSIOLOGY.

STAMP DUTIES, a branch of the public revenue, raised by requiring, that all deeds or documents, in order to be valid, shall be written on paper or parchment bearing a public mark or seal, for which a tax is paid.

STANDARD, in commerce, the original of a weight, measure or coin, committed to

trate, or deposited in some public place, to regulate, adjust, and try, the weights used by particular persons in traffic. The standards of weights and measures in England are appointed by Magna Charta to be kept in the exchequer, by a special officer, called the clerk, or comptroller of the market.

STANDARD, in war, a sort of banner, or flag, borne as a signal for the joining together of the several troops belonging to the same body.

The royal standard is a flag in which the imperial ensigns of England, Scotland, and Ireland, are quartered, together with the armorial bearings of Hanover.

STANDING, in the sea-language. Standing part of the sheet, is that part of it which is made fast to a ring at the ship's quarter. Standing part of a tackle, is the end of the rope where the block is fastened.

STANNARIES, the mines and works where tin is dug and purified, as in Cornwall, Devonshire, &c.

STAPLE primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people, as the Greve, or the places along the Seine, for sale of wines and corn, at Paris, whither the merchants of other parts are obliged to bring those commodities. Formerly the merchants of England were obliged to carry their wool, cloth, lead, and other like staple-commodities of this realm, in order to utter the same by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each whereof a public mart was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way.

STAR, in astronomy, a general name for all the heavenly bodies, which are dispersed throughout the whole heavens.

STAR *falling*, or *shooting star*, a luminous meteor darting rapidly through the air, and resembling a star falling. The explication of this phenomenon has puzzled all philosophers, till the modern discoveries in electricity have led to the most probable account of it. It is now allowed that this beautiful meteor is nothing more than an accumulation of electric matter passing through the nearer parts of the atmosphere.

STAR-BOARD, in the sea language, denotes the right-hand side of a ship.

STAR-SHOT, a gelatinous substance frequently found in fields, and is the half-digested food of herons, sea-mews, and the like birds; for these birds, when shot, have been found to disgorge a substance of the same kind.

STARCH. If a quantity of wheat-flour is formed into a paste, and then held under a very small stream of water, kneading continually till the water runs off from it colourless, the flour by this process is divided into two distinct constituents. A tough substance of a dirty-white colour, called gluten, remains in the hand; the water is at first milky, but soon deposits a white powder, which is known by the name of starch.

STATICE, *thrift*, a genus of plants belonging to the class of pentandria, and order

of pentagynia; and in the natural system ranging under the forty-eighth order, aggregate.

STATICS, that branch of mathematics which considers the motion of bodies arising from gravity.

STATIONERS. This extensive and highly respectable branch of trade, is said to have been so called from the circumstance of the traffic in books, paper, &c. having formerly been so inconsiderable, that those who dealt in such articles had no shops, but only stalls and stands in the streets.

STATISTICS, a word lately introduced to express a view or survey of any kingdom, county, or parish.

STATUARY, a branch of sculpture, employed in the making of statues.

STATUES, are figures, representing living or deceased creatures, of whatever species, real or imaginary; and carved, cast, modelled, or moulded, in full relievo, insulated on every part. Statues are formed with the chisel, of several materials, such as marble, stone, &c.; they are carved in wood, or cast in plaster of Paris, or other matter of a similar nature: they are also often cast in various kinds of metals.

STATUTE, in its general sense, signifies a law, ordinance, decree, &c. Statute, in our laws and customs, more immediately signifies an act of parliament made by the three estates of the realm; and such statutes are either public, of which the courts at Westminster must take notice, without pleading them; or they are special and private, which last must be pleaded.

Statutes, or *statutes sessions*, otherwise called petit sessions, are a meeting in every hundred, of all the shires in England, where by custom they have been used, whereto the constables and others, both house-holders and servants, repair for the debating of conferences between masters and servants, the rating of servants' wages, and bestowing such people in service, as being fit to serve, either refuse to seek or get masters.

STAVE, in music, the five horizontal and parallel lines on and between which the notes are placed.

STAUROLITE, in mineralogy. This stone has been found at Andresberg, in the Hartz. It is crystallized, and the form of its crystals has induced mineralogists to give it the name of cross-stone. Its crystals are two four sided flattened prisms, terminated by four sided pyramids, intersecting each other at right angles; the plane of intersection passing longitudinally through the prism.

STEALING, the fraudulent taking away of another man's goods, with an intent to steal them, against or without the will of him whose goods they are.

STEAM, a term used to designate the vapour produced by the application of heat to fluid bodies.

Steam Engine. The steam engine has with great propriety been denominated the triumph of mechanics. It is an engine now widely used, wherever great power is wanted; and this power is produced by giving a mechanical direction to the steam or vapour of boiling water.

The merit of this grand invention is generally attributed to the Marquis of Worcester; but if the first idea originated with him, the perfecting of it belongs to the immortal James Watt, a native of Greenock. The improvements that have been made in the construction of the steam engine within the last twenty years, are so numerous, that in our little work it would be preposterous to attempt to describe them. We shall therefore content ourselves with giving our readers a brief description, and a representation of a modern steam engine, which may, of course, be constructed of any required power, and applied to any purpose.

In plate XLVII, A, represents a wrought iron boiler, about three parts filled with water; the bottom is considerably, and the sides a little, concave, that it may receive more fully the force of the flame circulating round it. Boilers are usually of an oblong form, and are furnished with a part that takes off, in order that a person may get in to clean them when needful; they have also a valve, called the safety-valve, opening upwards, which is loaded so that the steam escapes when it is stronger than the engine requires, and, if retained, would hazard the bursting of the boiler. It is not uncommon to have two boilers, one of which is a reserve, that the engine may not be stopped, when the other requires repair.

B, is an apparatus for regulating the fire, and giving action to a bell, which regulates the quantity of coals and time of firing.

C, the steam-pipe from the boiler A to the valve I.

D, the steam cylinder, generally called only "the cylinder;" it is connected at the top and bottom with the valve I.

E, the piston, which, by its connecting rod *e*, gives motion to the beam F, the other end of which, by another connecting rod, gives motion to the heavy fly-wheel G, by means of a crank. Thus, after the engine has begun to work, its power is accumulated in the fly-wheel, and may be disposed of at the pleasure of the mechanist.

H, an eccentric circle on the axle of the fly-wheel G; it gives motion by its levers, to the valve I.

I, a coffer-slide valve, which requires no packing to make it steam-tight, as there is always a vacuum under it: it answers the purpose of the four valves used in double-power engines, and from the simplicity of its construction, when well made at first, is not liable to get out of order.

K, the steam-admission valve and lever, connected with a governor, which regulates the speed of the engine.

L, the cylinder of the discharging pump, for extracting the water and uncondensed vapour from the condenser M.

N, a small cistern, filled with water. Into this cistern enters a pipe from the condenser M, the top of which pipe is covered by a valve, which is called the blow-valve, sometimes the shifting valve. Through this valve the air contained in the cylinder D, and passages from it, is discharged, previously to the engine being set in motion.

O, the eduction-pipe, which conducts the steam from the valve I to the condenser M.

P, the pump which supplies with water the cistern SS. in which the condenser and discharging pump stand.

QQ, iron columns, of which the engine has

four, although only two are shewn; they stand upon one entire plate seen edgeway, on which the principal parts of the engine are fixed; by this means the beam and its accompaniments are supported without being connected with any part of the building, except the recess below the floor on which they stand.

RR, the recess below the floor, for containing the cistern of the discharging-pump, condenser, &c. This arrangement enables those engines to be fixed up and tried at the manufactory before they are sent off, which renders the refixing easy and certain.

Before the engine is set to work, the cylinder D, the condenser M, and the passages between them, are filled with common air, which it is necessary to extract. To effect this, by opening the valves, a communication is made between the steam-pipe C, the space below the piston in the cylinder D, the eduction-pipe O, and the condenser M. The steam will not at first enter the cylinder D, or will only enter it a little way, because it is resisted by the air; but the air in the eduction-pipe O, and the condenser M, it forcibly drives before it, and this part of the air makes its exit through the valve and water in the cistern N. The steam-admission valve is now closed, and the steam already admitted is converted into water, partly by the coldness of the condenser M, but principally by a jet of cold water which enters it through a cock opening into it from the well SS, in which the condenser is immersed. When this steam is condensed, all the space it occupied would be a vacuum, did not the air in the cylinder D expand, and fill all the space that the original quantity of it filled; but by the repetition of the means for extracting a part of the air, the remainder is blown out, and the cylinder becomes filled with steam alone. Suppose then the cylinder beneath the piston to be filled with steam, and the further admission of steam to that part of it be cut off, while the communication between it and the condenser remains open, it is obvious that there will soon be a vacuum in the cylinder, because as fast as the steam reaches the condenser, it is converted into water by the coldness of that vessel and the jet playing within it. At this moment, therefore, the steam is admitted above the piston, which it immediately presses down. As soon as the piston reaches to the bottom of the cylinder, the steam is admitted to the under side of it; and as the communication from the upper side of the piston to the condenser is opened, while the further admission of steam to that side during the upper stroke, is prevented, the steam which had pressed the piston down passes into the condenser, and is converted into water.

The motion of the piston E, by this alternate admission and extraction of the steam on each side of it, is thus necessarily continued, and the distance of its upward and downward range is called the length of its stroke. It communicates its reciprocating motion, by the connecting rod *e*, to the great beam F, and thence, by another connecting-rod and a crank, to the fly-wheel G.

To explain the rapid accumulation of power with an increase of the size of the engine, it must be observed, that the force of the steam generally used, is somewhat greater than the pressure of the atmosphere; but supposing it to be no greater, as the atmospheric pressure is fifteen pounds on each square inch, a piston 16 inches in diameter, containing 201 square inches of surface, will alternately be raised and depressed by a force equivalent to a weight of 3015 pounds. Here no allowance is made for friction, but after the requisite deduction on this account, which may be reckoned at one-third, the disposable part of the engine, derived from each stroke, will still be very great.

The condenser M, and the discharging-pump L, communicate by means of a horizontal pipe containing a valve *y* opening towards the pump; the piston, *l*, of this pump, also contains two valves, and the cistern T, at the top of the pump-cylinder, contains other two valves, which, like those of the piston *l*, open upwards. When the piston E of the cylinder is depressed, the piston *l*, of the discharging-pump, it will be obvious to inspection, is depressed likewise, and its valves open, while the valve *y* closes; hence the water from the condensed steam, as well as the injection-water, and any permanently elastic vapour or gas, which may be present, having passed through the valve *y*, passes through the piston *l*: and when that piston is drawn up, its valves close, and prevent their return, as in ordinary pump-work. The water and gas that have thus got above the piston, as the latter rises, open the valves at the bottom of the cistern T, in which the water remains till it is full, but the gas passes into the atmosphere. As the water in the cistern T is in a very hot state, it is sometimes, for the purpose of economizing fuel, pumped up, and returned to the boiler, the pump-rod being attached to the great beam. The utility of the discharging-pump L, will now be appreciated, and it must be perceived how much mo[illegible] materially it contributes to the perfection of the vacuum in the cylinder D, than if the water from the condenser merely ran off by a pipe.

The steam constantly rushing into the condenser M, has a perpetual tendency to heat that vessel, as well as the water of the cistern SS, in which it stands: the whole of the steam, if this were unchecked, would not be condensed, or the condensation would not be sufficiently rapid, because the injection-water itself flows out of this cistern. A part of the water is therefore allowed to flow from this cistern by a waste pipe, and an equal quantity of cold is constantly supplied by the pump P.

In Newcomen's engine, which, as it acted by the pressure of the atmosphere, is often called an atmospherical engine, the cylinder was open at the top, and therefore, during the descent of the piston, the air exerted a great power in cooling it; but in the modern engines, where steam is the active power both in raising and depressing the piston, the top of the cylinder is closed with an iron lid, and not an atom of steam can escape, except at the proper time, into the condenser. In order that the connecting rod *e*, may work freely, and yet possess this desirable property of being steam-tight, it passes through what is called a *stuffing* or *packing box*. This stuffing consists of some material which the steam will rather adapt to its office than injure: leather, which is used for the stuffing or collars of machines

never to be subjected to heat, will not answer here; hempen yarn is the material usually employed. The rod of the piston *l*, passes through a stuffing box of the same kind as that of the piston E; and the pistons themselves are surrounded with stuffing.

The cylinder D is surrounded by a case, to keep it from being cooled by contact with the external air. The extremity, or any given point removed from the centre of the great beam, can describe only the arc of a circle; but it is necessary that the piston rod *e* should rise and fall vertically. Newcomen effected this object, by fixing the end of the beam into the arc of a circle, the radius of which was equal to the distance from the centre of the beam: a chain went over this arc, and was fastened on the higher end of it; this simple contrivance effectually answered his purpose, because in his engine the effective stroke was only downwards; but here, in a double-power engine, where the stroke is both upwards and downwards, a chain would yield in rising, and be altogether unsuitable. An apparatus is therefore used, called the parallel joint, which is easily understood by inspection. By this means the rod *e*, not only rises and falls perpendicularly, but is perfectly rigid, and communicates all its motion to the great beam in each direction of its motion. The connecting rod *g* does not require the same contrivance, because it does not rise and fall perpendicularly; its lower end, with the outer end of the crank, describing a circle: it has therefore only a simple joint, admitting of this deviation.

STEEL, a carburet of iron, or that metal combined with a small portion of carbon. See Iron.

STEERAGE, on board a ship, that part of the ship next below the quarter-deck, before the bulk-head of the great cabin, where the steersman stands in most ships of war.

STEERING, in navigation, the directing a vessel from one place to another by means of the helm and rudder. He is held the best steersman who causes the least motion in putting the helm over to and again, and who best keeps the ship from making yaws, that is, from running in and out. The perfection of steering, indeed, consists in a vigilant attention to the motion of a ship's head, so as to check every deviation from the line of her course in the first instant of motion, and in applying as little of the power of the helm as possible.

STEM, in botany, that part of a plant arising out of the root, and which sustains the leaves, flowers, fruits, &c.

Stem *of a ship*, that main piece of timber which comes bending from the keel below, where it is scarfed, as they call it; that is, pieced in; and rises compassing right before the forecastle.

STENOGRAPHY, or the art of short-hand writing, is an acquirement which, in the present advanced state of literature and science, every person who receives even a common education, ought to possess. Of the various systems of short-hand writing now before the public, the following is here preferred for its great simplicity; the facility with which the characters may be joined; and the ease with which it may be read when written.

The author of this system was John Byrom, M. A. and F. R. S.; and it was since Byrom's time improved by Mr. Molineux, of Macclesfield. The general fault of most short-hand alphabets is their being encumbered with vowels as distinct letters; in this system they are expressed by one dot, *differently situated*; but the student is advised to reject the use of them altogether, unless, indeed, in cases where they are necessary to prevent ambiguity.

A close attention to the plates, and the few following remarks, will enable any one accustomed to writing, speedily to become acquainted with this most useful art.

The alphabet, as exhibited in the plate, consists of the shortest and simplest marks in nature; and on the proper formation and combination of these, depend the whole beauty and accuracy of the writing.

The twenty-one consonants which compose the short-hand alphabet, are formed out of simple lines, to some of which are attached small loops or twirls. These lines derive their respective powers and properties from their difference of position, and by some of them being made curvilineal.

The horizontal characters are always to be written from left to right; the perpendicular ones are invariably written downwards; and with respect to the oblique characters, it is to be observed, that those which lean to the left are generally written upwards, while those having their inclination to the right hand, are always written downwards.

Not any of the twirled letters (the duplicate characters denoting *h, j, w,* and *sh,* which are never joined to any other letters; but simply stand for the words *had, just, would,* and *should,* excepted) ought ever to be written so as to end with the loop. This observation must not be forgotten by the learner, and he will never be at a loss about the manner of joining the looped characters to other letters.

The following general rules must be carefully attended to by the short hand writer, viz.:

1. All perpendicular and inclined letters are made to touch, as it were, to imaginary parallel lines, the distance of which from each other is supposed to be regulated by the length of the short hand *t*.
2. The diameter of the semicircular letters is the short-hand *s*, and their height rather more than one third of the *t*.
3. The *t* is occasionally used for *th*, in which case the adjoining letter must be made only half its regular size.
4. No letters are to be doubled in short-hand unless some vowel come between them.
5. When there are various ways of joining the same letters together, that which is most lineal must be preferred.

As soon as the learner can write any passage with readiness, using the characters in full, he may proceed to the following abbreviated method, which he will find both advantageous and delightful; and which will enable *him* with a little industrious practice to follow the most rapid speaker.

RULES OF ABBREVIATION.

For the short-hand characters answering to the examples in the following rules the reader must refer to Plate XLIX.

1. The auxiliary verbs, the participle *not* and the pronouns, being severally denoted by

their first consonant, may be joined to one another; as *can be, will be, have not been.*

2. Join the marks or letters in an unusual manner, in order to show that each particular mark denotes a word, and not a single letter; as, by joining the letter *n* to the middle instead of the top of the letter *t*, the whole character will represent the words *in the;* so, also, the letter *s*, joined to the letter *t*, and drawn from the middle of the preceding consonant, will denote the two words *it is*, or *it was.*

3. Derivative nouns, adjectives, and adverbs, may be very conveniently expressed by points, differently placed, at the end of their last consonant. The substantive point being placed immediately following the consonant, and in a direct line with it; the adjective to have its point placed also a little lower down to the left of the substantive point; and the adverb point to be placed, in the same manner, to the right of the substantive point; as *forgetfulness, forgetful, forgetfully.*

4. Very common words, or such as have an immediate relation to the subject, and are therefore easily discoverable, may be denoted by their first consonant, or first vowel and consonant, with the substantive, adjective, or adverb point annexed. The adjectives, which usually accompany such substantives, may also be denoted by their first consonant, joined to the substantive; as *humble servant, human nature, Christian religion*, &c.

5. Place a dot at the point of concurrence of two consonant marks, to denote two substantives connected together by some preposition, which is omitted; as *love of God*, or *light of the gospel*; *cause of gravity*, &c. Also when an adjective precedes either of the substantives, they may all three be represented by their first consonants joined together, with the dot placed at the end of the first substantive; as the *great goodness of God.*

6. The substantive point, placed before a single consonant mark, denotes that the substantive is to be repeated, with some intervening preposition; as *day after day*; from *time to time*, &c.

7. Place the substantive, adjective, or adverb point before two or more consonant marks, to denote two or more substantives, adjectives or adverbs, connected by a conjunction; as *King, Lords*, and *Commons, soberly, righteously*, and *godly*, &c.

8. Express long words by their first syllable with as many points annexed as there are syllables wanting. In very common words the points may be occasionally omitted.

9. Express long words by their prepositions, together with their next vowel or consonant only.

10. Words may be denoted by their first vowel and consonant, with their terminations added; as *arbitrary, opportunity*, &c.

11. Words easily discovered by their connection, may be expressed by their first vowel and consonant, or by their prepositions only; and as few English words end with the syllable *to*, the preposition *to* may be joined to the preceding word; as *belongs to*; *satisfactory to*, &c.

12. Join the pronouns to prepositions; as *to me, to us, to you*, &c., always adding the vowel point, when the words would otherwise be liable to be mistaken.

13. Join the preceding word, the preposition, and pronoun all together; as *belongs to me agreed with me*, &c.

14. Join adverbs, verbs, prepositions, pronominal adjectives, and substantives all together; as *safely depend upon my word*, &c.

15. Many common phrases, formed by substantive, preceded by the prepositions *with, without, in*, &c. and followed by *to, of*, &c. may be abbreviated; as *with regard to*; *in consequence of*, &c. These several words are expressed by their first consonants only, joined together, the vowel *o* being added in the first example to denote the preposition *to.*

16. In like manner, denote common adverbial phrases by the initial consonants joined together; as *in like manner*; *in particular*; *in a great measure*, &c.

17. Numerous contractions may be made when *it is*, or *it was*, are followed by an adjective, and *to*, or *that*; as *it is impossible to*; *it is not to be supposed that*, &c.

18. The termination *ing* is made by a short line in the position of the *r*, and the plural by two such lines   *king, kings*; *writing, writings.*

STEREOGRAPHY, the art of drawing the forms and figures of the solids upon a plane.

STEREOTYPE PRINTING. See PRINTING.

STERLING, a term frequent in British commerce. A pound, shilling, or penny, sterling, signifies as much as a pound, shilling, or penny, of lawful money of Great Britain, as settled by authority.

STERN *of a ship*, usually denotes all the hindermost part of her, but properly it is only the aftmost part abaft.

STERNA, *the tern*, a genus of birds of the order anseres. The marks of this genus are a straight, slender, pointed bill, linear nostrils, a slender and sharp tongue, very long wings, a small back toe, and a forked tail. There are 25 species.

STEWARD, a man appointed in a place or stead, and always signifies a principal officer within his jurisdiction.

STICK, the same as baton, an instrument of dignity, which is occasionally carried by persons and officers in high situations, particularly by such as are in waiting near the royal person.

STIGMA, in botany, the summit of the style, the female organ of generation in plants, which receives the fecundating dust of the tops of the stamina, and transmits its effluvia through the style into the heart of the seed-bud, for the purpose of impregnating the seeds.

STILL. See DISTILLATION.

STING, an apparatus in the body of certain insects, in form of a little spear, serving them as a weapon of offence.

STOCKING, that part of the clothing of the leg and foot which immediately covers their nudity, and screens them from the cold, &c. Anciently, the only stockings in use were made of cloth, or of milled stuffs sewed together; but since the invention of knitting and weaving stockings of silk, wool, cotton, thread, &c. the use of cloth stockings is quite laid aside. The modern stockings, whether woven or knit, are a kind of plexuses, formed of an infinite number of little knots, called stitches, loops, or meshes, intermingled in one another.

STOCKS, or *Public Funds in England.* By the word stock was originally meant a particu

lar sum of money contributed to the establishing of a fund to enable a company to carry on a certain trade, by means of which the person became a partner in that trade, and received a share of the profit made thereby, in proportion to the money employed.

Stocks, among ship-carpenters, a frame of timber, and great posts made ashore, to build pinnaces, ketches, boats, and such small craft, and sometimes small frigates. Hence we say, a ship is on the stocks when she is a building.

Stocks, a wooden machine to put the legs of offenders in, for the securing of disorderly persons, and by the way of punishment in divers cases, ordained by statute, &c.

STOLE, *groom of the*, the eldest gentleman of his majesty's bed-chamber, whose office and honour it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber.

STOMOXYS, a genus of insects of the order diptera: the generic character is, sucker with a single-valved sheath, inclosing bristles, each in its proper sheath; feelers two, short, setaceous, of five articulations; antennæ setaceous.

STONES and EARTHS. The only substances which enter into the composition of the simple stones, as far at least as analysis has discovered, are the six earths, silica, alumina, zirconia, glucina, lime, and magnesia; and the oxides of iron, manganese, nickel, chromium, and copper. Seldom more than four or five of these substances are found combined together in the same stone.

STONEHENGE, a famed pile or monument of huge stones on Salisbury Plain, six miles distant from that city. It consists of the remains of four ranks of rough stones, ranged one within another, some of them, especially in the outermost and third rank, twenty feet high, and seven broad; sustaining others laid across their heads and fastened by mortices, so that the whole must have anciently hung together. Antiquaries are now pretty well agreed that it was a British temple.

STONE WARE. Under the denomination stone ware are comprehended all the different artificial combinations of earthy bodies which are applied to useful purposes.

STOP, in music, a word applied by violin and violoncello performers to that pressure of the strings by which they are brought into contact with the finger-board, and by which the pitch of the note is determined.

STOP, TRUMPET. A reed metallic stop, so called because its tone is imitative of the trumpet.

STORES. If any person who has the charge or custody of any of the king's armour, ordnance, ammunition, shot, powder, or habiliments of war, or of any victuals for victualling the navy, shall, to hinder his majesty's service, embezzle, purloin, or convey away the same to the value of 20*s.* or shall steal or embezzle any of his majesty's sails, cordage, or any other of his naval stores, to the value of 20*s.* he shall be adjudged guilty of felony without benefit of clergy.

STRANDED, among seamen, is said of a ship that is driven ashore by a tempest, or runs on ground through ill steerage, and so perishes.

STRATA, in natural history, the several beds or layers of different matters, whereof the body of the earth is composed.

STRIKE, a measure of capacity, containing four bushels.

Strike, among seamen, is a word variously used. When a ship, in a fight, or on meeting with a ship of war, lets down or lowers her topsails, at least half-mast-high, they say she strikes, meaning she yields, or submits, or pays respect to the ship of war. Also, when a ship touches ground, in shoal-water, they say she strikes. And when a top-mast is to be taken down, the word of command is, strike the top-mast, &c.

STRIX, the *owl*, in ornithology, a genus belonging to the order of accipitres. The bill is hooked, but has no cere or wax; the nostrils are covered with setaceous feathers; the head is very large, as are also the ears and eyes; and the tongue is bifid. There are 46 species.

STRONTIAN. About the year 1737, a mineral was brought to Edinburgh by a dealer in fossils, from the lead mine of Strontian, in Argyleshire, where it is found imbedded in the ore, mixed with several other substances. It is sometimes transparent and colourless, but generally has a tinge of yellow or green. Its specific gravity varies from 3.4 to 3.726. Its texture is generally fibrous; and sometimes it is found crystallized in slender prismatic columns of various lengths. Strontian is found abundantly in different places of the world, and always combined with carbonic acid or sulphuric acid.

The beautiful red fire which is now so frequently used at the theatres, is composed of the following ingredients 40 parts dry nitrate of strontian, 13 parts of finely powdered sulphur, 5 parts of chlorate of potash, (hyperoxymuriate) and 4 parts of sulphuret of antimony. The chlorate of potash and sulphuret of antimony should be powdered separately in a mortar, and then mixed together on paper, after which they may be added to the other ingredients, previously powdered and mixed. No other kind of mixture than rubbing together on paper is required. See Chemistry.

STRUTHIO, the *ostrich*. The ostrich has a bill somewhat conical; the wings are so short as to be unfit for flying; the thighs and sides of the body are naked: the feet are formed for running, having two toes, one only of which is furnished with a nail. The head and bill somewhat resemble those of a duck; and the neck may be likened to that of a swan, but that it is much longer; the legs and thighs resemble those of a hen, though the whole appearance bears a strong resemblance to that of a camel. But though usually seven feet high from the top of the head to the ground, from the back it is only four; so that the head and neck are above three feet long.

From the top of the head to the rump, when the neck is stretched out in a right line, it is six feet long, and the tail is about a foot more One of the wings without the feathers, is a foot and a half; and being stretched out, with the feathers, is three feet. The plumage is much alike in all; that is, generally black and white; though some of them are said to be grey. There are no feathers on the sides, nor yet on the thighs, nor under the wings. The lower part of the neck, about half-way, is covered with

still smaller feathers than those of the belly and back, and these also are of different colours. At the end of each wing there is a kind of spur almost like the quill of a porcupine. It is an inch long, being hollow and of a horny substance. There are two of these on each wing; the largest of which is at the extremity of the bone of the wing, and the other a foot lower. The neck seems to be more slender in proportion to that of other birds, from its not being furnished with feathers. The skin in this part is of a livid flesh-colour. The bill is short and pointed. The external form of the eye is like that of a man, the upper eye-lid being adorned with eye-lashes which are longer than those on the lid below. The tongue is small, very short, and composed of cartilages, ligaments, and membranes, intermixed with fleshy fibres. In some it is about an inch long, and very thick at the bottom; in others it is but half an inch, being a little forked at the end.

The ostrich is a native only of the torrid regions of Africa, and has long been celebrated by those who have had occasion to mention the animals of that region.

STRUTHIOLA, a genus of plants belonging to the class of tetrandria, and order of monogynia. The species are five, shrubs of the Cape.

STUCCO, in building, a composition of white marble pulverised, and mixed with plaster of lime; and the whole being sifted and wrought up with water, is to be used like common plaster: this is called by Pliny marmoratum opus, and albarium opus.

STUM, in the wine trade, denotes the unfermented juice of the grape, after it has been several times racked off, and separated fro its sediment.

STURGEON. See ACCIPENSER.

STYLE, a word of various significations, originally derived from ςυλος, a kind of bodkin, with which the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory leaves, and paper prepared for that purpose, &c.

SUBALTERN, a subordinate officer, or one who discharges his post under the command and subject to the direction of another; such are lieutenants, sub-lieutenants, cornets, and ensigns who serve under the captain, but custom has now appropriated the term to those of much lower rank, as serjeants, &c.

SUBER. This name has been introduced into chemistry by Fourcroy, to denote the outer bark of the quercus suber, or the common cork, a substance which possesses properties different from all other vegetable bodies.

SUBLIMATION is a process by which volatile substances are raised by heat, and again condensed in the solid form.

This operation is founded on the same principles as distillation, and its rules are the same, as it is nothing but a dry distillation.

SUBPŒNA, is a writ whereby all persons under the degree of peers are called into Chancery, in such cases only where the common law fails, and has made no provision; so as the party who in equity hath wrong, can have no other remedy by the rules and course of common law.

SUBSIDY, in law, signifies aid or tax granted to the king, by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods.

SUCCINIC ACID. It has long been known that amber, when exposed to distillation, affords a crystallized substance, which sublimes into the upper part of the vessel. Before its nature was understood it was called *salt of amber*: but it is now known to be a peculiar acid, as Boyle first discovered.

SUGAR exists in every part of plants. It is found in the roots, as those of the carrot and beet root; in the stems, as in the birch, the maple, some palms, and especially the sugar cane; in the leaves, as those of the ash; in the flowers, the fruits, and seeds. But the sugar, which now forms a very extensive article of commerce, and may be considered as a necessary of life, is entirely obtained from the juice of the sugar cane, which is chiefly cultivated in the East and West Indies

SUGAR *of lead*, acetate of lead.

SUIT, in law, is used in different senses, as. 1. Suit personal. 2. Suit of court, or suit service, is an attendance that tenants owe to the court of their lord. 3. Suit covenant, is where the ancestor has covenanted with other, to sue to his court. 4 Suit custom, when a man and his ancestors have been seized time out of mind, of his suit. 5. Suit real, or legal, when men come to the Sheriff's torn or leet. 6. Suit signifies the following one in chace, as fresh suit. 7. It signifies a petition made to the king or any great person.

SULPHATES. Definite compounds of sulphuric acid with the salifiable bases. See ACID (SULPHURIC,) and the respective bases.

SULPHITES. Definite compounds of sulphurous acid with the bases.

SULPHUR. See CHEMISTRY.

SULPHURIC ACID. The sulphuric acid made in Great Britain is produced by the combustion of sulphur. There are three conditions requisite in this operation. Oxygen must be present to maintain this combustion; the vessel must be so close as to prevent the escape of the volatile matter which rises, and water must be present to imbibe it. For these purposes, a mixture of eight parts of sulphur with one of nitre is placed in a proper vessel, enclosed within a chamber of considerable size, lined on all sides with lead, and covered at bottom with a shallow stratum of water. The mixture being set on fire, will burn for a considerable time by virtue of the supply of oxygen which nitre gives out when heated, and the water imbibing the sulphurous vapours, becomes gradually more and more acid after repeated combustions, and the acid is afterward concentrated by distillation.

SUMACH. Common sumach (rhus coriaria) is a shrub that grows naturally in Syria, Palestine, Spain, and Portugal. In the two last, it is cultivated with great care. Its shoots are cut down every year quite to the root; and, after being dried, they are reduced to power by a mill, and thus prepared for the purposes of dyeing and tanning.

SUPERCARGO, a person employed by merchants to go a voyage, and oversee their cargo, or lading, and dispose of it to the best advantage.

SUPERNUMERARY, something over and above a fixed number. In several of the offices

are supernumerary clerks, to be ready on extraordinary occasions. There are also supernumerary surveyors of the excise, to be ready to supply vacancies when they fall; these have but half-pay.

SUPERSEDEAS, a writ that lies in a great many cases, and signifies, in general, a command to stay proceedings, on good cause shown, which ought otherwise to proceed. By a supersedeas, the doing of a thing which might otherwise have been lawfully done, is prevented; or a thing that has been done, is (notwithstanding it was done in a due course of law) thereby made void.

SURD. See ALGEBRA.

SURETY, in law, generally signifies the same with bail.

SURETY *of the peace*. A justice of the peace may, according to his discretion, bind all those to keep the peace, who, in his presence shall make any affray, or shall threaten to kill or beat any person, or shall contend together in hot words; and all those who shall go about with unlawful weapons or attendance to the terror of the people; and all such persons as shall be known by him to be common barrators; and all who shall be brought before him by a constable for a breach of the peace in the presence of such constable: and all such persons who, having been before bound to keep the peace, shall be convicted of having forfeited their recognizance.

SURGERY, is the art of curing or alleviating diseases by local and external application, manual or instrumental. As a science it may be defined, that department of medicine which treats of maladies thus susceptible of alleviation or cure.

SURRENDER, a deed or instrument, testifying that the particular tenant of lands or tenements for life, or years, does sufficiently consent and agree, that he who has the next or immediate remainder or reversion thereof, shall also have the present estate of the same in possession; and that he yields and gives up the same to him; for every surrenderer ought forthwith to give possession of the thing surrendered.

SURROGATE, one who is substituted or appointed in the room of another; as the bishop or chancellor's surrogate.

SURVEYING. The art of land surveying consists in determining the boundaries of an extended surface; and when used in its most extensive sense, may be said to comprehend the taking the dimensions of any given tract of land; laying down the same in a plan on any required scale; and finding the superficial contents, or area of the same. The principal instruments used by surveyors are the chain, the off-set staff, the plain-table, the cross, and the theodolite. The plain-table is now little used; it is found often incorrect; and he who would operate correctly ought to be in possession of a good four inch theodolite, having on it at least two spirit levels.

It was our intention to have laid down some general rules for the practice of surveying and to have given some examples; but we find our limits will not admit of this; and we must, therefore, refer our readers for the necessary information on this subject, to the popular treatises on it which are now before the public; among which, that of Croker, and the excellent epitome given by Mr. Peter Nicholson in his Course of Mathematics, deserve particular attention.

The foundation of all surveying is geometry; and no one will ever be able to practice it to any extent without a knowledge of the principal rules of plane trigonometry, which see.

SUS, the *hog*, in natural history, a genus of mammalia, of the order of belluæ. Generic character: four front teeth in the upper jaw, converging; six in the lower, projecting; two tusks in the upper jaw, short; two in the lower standing out; snout truncate, prominent, and moveable: feet cloven. These animals are allied by their teeth to the carnivorous quadrupeds, and by their cloven feet to the ruminating ones. They feed almost indifferently upon animal and vegetable substances, devouring with avidity what is most nauseous and disgusting. They use their snout for digging up the ground in quest of roots, are fond of rolling and wallowing in mud, and are distinguished by extreme fecundity. There are six species, of which the following are the most important:

Sus, crofa, the common hog. All the varieties of this animal originate in the wild boar, which is found in most of the temperate regions of Europe and Asia. It is smaller than the domesticated animal, and uniformly of a dark grey colour, approaching to black. It is armed with formidable tusks, sometimes ten inches, or even more, in length; those in the under jaw curving inwards, and capable from their size, strength, and sharpness, of inflicting the severest wounds. Before these animals attain their third year they are gregarious, and when danger is at hand particularly, they muster in numerous parties, and with great promptitude, at the signal of alarm. Uniting thus, they present so formidable an array, as speedily to disperse the enemy, few creatures, or none, daring to commence an attack against such a combination of strength and valour as they exhibit. When the wild boar is complete in growth, he depends upon his solitary exertions for his protection, is seldom seen in society, ranging the forests alone; rarely commencing an attack, as his food consists almost solely of roots and vegetables, but repelling one with all the fierceness of courage, and all the resentment of rataliation.

Sus, Ethiopicus, or the Ethiopian hog, is very similar to the last. It is fierce and formidable in the highest degree, and burrows in the ground, in deep recesses which it prepares with both its hoofs and nose. It is particularly distinguished by a large lobe, or wattle, beneath each eye.

S. baby-roussa is remarkable for the form and situation of the upper tusks, which are placed externally, and turn upwards in a curve towards the forehead. It abounds in the Indian islands, lives solely on vegetables, and rests itself, in sleep, by hooking its upper tusks round the branch of a tree. It can swim with rapidity, and is valued for food.

SUSPENSION, or POINTS of SUSPENSION, in mechanics, are those points in the axis or beam of a balance, wherein the weights are applied, or from which they are suspended.

SWEDENBORGIANS a term used to designate the receivers of the doctrines taught

by the Hon. Emanuel Swedenborg, a native of Sweden. They form a highly respectable, and remarkably intelligent body of Christians. Since the death of Swedenborg, which took place in London, in the year 1772, their numbers have gradually increased, both in this country, on the continent, and in America. They have suffered much from ignorant and interested misrepresentation; and it is a remarkable fact, that the writings of their founder have never been attacked by any man of talent, if we except Dr. Priestley, who, in the attempt, met with a most signal defeat, by Mr. Hindmarsh, of Manchester. Among the admirers of the works of Swedenborg, might be mentioned several eminent divines, and numerous members of the Church of England. While the various sects into which the Christian world is divided, are zealously exerting themselves for the diffusion of religious knowledge, the Swedenborgians are far from being idle. They have their schools for the instruction of the rising generation, their Missionary and Tract Societies, and also societies for printing and publishing the theological writings of Swedenborg. Their exertions have excited considerable attention in this country within the last few years. The consequence of this has been some most illiberal attacks on their doctrines by some dissenting ministers. These have drawn forth a reply from Mr. Samuel Noble, minister of Hanover-street Chapel, London, to which we refer the reader for a most interesting and able detail of the principles and practice of this body of Christians.

SWIETENIA, *mahogany*, a genus of plants belonging to the class of decandria, and to the order of monogynia; and in the natural system arranged under the 54th order, miscellaneæ. There are three species: the mahogany, which is the principal, is a native of the warmest parts of America, and grows also in the island of Cuba, Jamaica, Hispaniola, and the Bahama islands. It abounded formerly in the low lands of Jamaica, but it is now found only on high hills and places difficult of access.

SWIMMING, the act of sustaining the body in water, and of moving in it, in which action the air-bladder and fins of fishes bear each a considerable part.

There is now in London, a public institution where the art of swimming is regularly taught.

SWIME-*stone*, in mineralogy, a variety of compact luculite, a sub-species of limestone.

SWIVEL, in gunnery, a small piece of artillery carrying a shot of half a pound weight, and fixed in a socket on the top of a ship's side, stern, or bow, and also in the tops; the trunnions of this piece are contained in a sort of iron croach, the lower end of which terminates in a cylindrical pivot, resting in the socket so as to support the weight of the cannon. By means of this swivel, which gives name to the piece of artillery, and an iron handle, the gun may be directed by hand to any object.

SWORD, an offensive weapon, worn at the side, and serving either to cut or stab. Its parts are the handle, guard, and blade; to which may be added the bow, scabbard, pummel, &c.

SYLLOGISM, συλλογισμος, in logic, an argument or term of reasoning, consisting of three propositions; the two first of which are called premises, and the last the conclusion.

SYMPHONY, in music, properly denotes a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony.

SYNGENESIA, in botany, the name of the nineteeth class in Linnæus's system, consisting of plants in which the anthers, or male organs of generation, are united into a cylinder the filaments on which they are supported being separate and distinct: this class contains the numerous tribe of compound flowers.

SYNGNATHUS, pipefish, a genus of fishes of the order nantes: the generic character is, snout subcylindric, with terminal mouth; body lengthened, jointed, mailed; ventral fins none There are eight species.

SYNOVIA, the name given to a liquid secreted within the capsular ligaments of the joints, to facilitate motion by lubricating these parts.

SYNTAX, in grammar, the proper construction, or due disposition of the words of a language, into sentences, or phrases: or the manner of constructing one word with another, with regard to the different terminations thereof, prescribed by the rules of grammar.

SYNTHESIS, the putting of several things together, as making a compound medicine of several simple ingredients, &c.

SYRINGE, an instrument serving to imbibe, or suck in a quantity of any fluid, and to squirt or expel the same with violence.

SYRINGIA, the lilac, a genus of plants of the class of diandria and order of monogynia; and in the natural system ranging under the 44th order, sepiariæ. There are three species, the vulgaris, persica, and suspensa.

SYRINTOLE, in anatomy, the contraction of the heart, whereby the blood is drawn out of its ventricles into the arteries; the opposite state to which is called the diastole, or dilation of the heart.

SYZYGY, in astronomy, a term equally used for the conjunction and opposition of a planet with the sun.

T.

T the nineteenth letter of our alphabet. In abbreviations, amongst the Roman writers, T. stands for Titus, Titius, &c. Ti. Tiberius; Ti. F. Tiberii filius. T. L. Tiberii libertus; Ti. N. Tiberii Nepos; T. J. A. V. P. V. D. tempora judicem arbitrumve postulat ut det; T M. P. terminum posuit; T M. D D. terminum dedicavit: Tr. trans. Tribunus: Tr M. or Mil. tribunus militum; T R. P L. D E S. tribunus plebis designatus; T R. A E R. tribunus ærarii; T R V. C A P. triumviri capitales; T. R. or TRIB. POT. tribunicia; Tul. H. Tulius Hostilius.

TABASHEER. The silica which is found

in the hollow stem of the bamboo is so named. Its optical properties are peculiar. They have been described by Dr. Brewster, *Phil. Trans.* 1819.

TABBY, in commerce, a kind of rich silk, which has undergone the operation of tabbying.

TABBYING, the passing a silk or stuff through a calender, the rolls of which are made of iron or copper, variously engraven: which bearing unequally on the stuff, renders the surface unequal so as to reflect the rays of light differently, making the representation of waves thereon.

TABLE, in perspective, denotes a plane surface, supposed to be transparent, and perpendicular to the horizon. It is always imagined to be placed at a certain distance between the eye and the object, for the objects to be represented thereon by means of the visual rays passing from every point thereof through the table to the eye; whence it is called perspective-plane.

TABLE, among the jewellers, a table-diamond, or rather precious stone, is that whose upper surface is quite flat, and only the sides cut in angles; in which sense a diamond cut tablewise, is used in opposition to a rose-diamond.

TABLE, in mathematics, systems of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations: thus we say, tables of the stars; tables of signs, tangents, and secants; tables of logarithms, rhumbs, &c. sexagenary tables

TACHYGRAPHY, the art of writing fast, or of short hand. See STENOGRAPHY.

TACK, in a ship, a great rope having a wale-knot at one end, which is seized or fastened into the clew of the sail: so is reefed first through the chess-trees, and then is brought through a hole in the ship's side.

TACKLE, or TACKLING, among seamen, denotes all the ropes or cordage of a ship, used in managing the sails, &c.

TACTICS, in their general acceptation, relate to those evolutions, manœuvres, and positions, which constitute the main spring of military and naval finesse: they are the means whereby discipline is made to support the operations of a campaign, and are, in every regular service, studied for the purpose of training all the component parts according to one regular plan or system; whereby celerity, precision, and strength are combined, and the whole rendered completely efficient.

TÆNIA, the TAPE-WORM, in zoology, a genus of animals belonging to the class of vermes, and order of intestina. The body is long, depressed, and jointed like a chain, and contains a mouth and viscera in each joint. According to Gmelin, there are 92 species; all which inhabit the intestines of various animals, particularly of quadrupeds.

Gmelin has divided them into sections as follow: A. Those found in other parts besides the intestines, and furnished with a vesicle behind. B. Those found in the intestines only, and without a terminal vesicle. C. Those with the head unarmed with hooks. The worms of the first section are found infesting mammalia, reptiles, and fish. Those of the second section are found in the mammalia, in birds, and in fish; and those of the third section infest mammalia, birds, reptiles, and fish. This genus of worms are destined to feed on the juices of various animals, and are usually found in the alimentary canal, generally at the upper part of it. They are sometimes found in great numbers, and occasion the most distressing disorders. They have the power of reproducing parts which have been broken off, and are therefore removed with the utmost difficulty: they are oviparous, and discharge their eggs from the apertures on the joints.

TAFFETY, in commerce, a fine smooth silken stuff, remarkably glossy. See SILK. There are taffeties of all colours, some plain, and others striped with gold, silver, &c.

TALC. Of this mineral, Professor Jameson's sixth sub-species of rhomboidal mica, there are two kinds; common talc, and indurated talc.

1. *Common talc.* Colour greenish-white. Massive, disseminated in plates, imitative, and sometimes crystallized in small six-sided tables, which are druses. Splendent, pearly, semi-metallic. Cleavage single, with curved folia. Translucent. Flexible, but not elastic. Yields to the nail. Perfectly sectile. Feels very greasy. Sp. gr. 2.77. It occurs in beds in mica-slate and clay-slate. It is found in Aberdeenshire, Banffshire, and Perthshire. The finest specimens come from Saltzburg, the Tyrol, and St. Gothard. It is an ingredient in rouge for the toilette, along with carmine and benzoin. This cosmetic communicates a remarkable degree of softness to the skin, and is not injurious. The flesh polish is given to gypsum figures, by rubbing them with talc.

2. *Indurated talc*, or *talc-slate.* Colour greenish-grey. Massive. Fragments tabular. Translucent on the edges. Soft. Streak white. Rather sectile. Easily frangible. Not flexible. Feels greasy. Sp. gr. 2.7 to 2.8. It occurs in primitive mountains, where it forms beds in clay-slate and serpentine. It is found in Perthshire, Banffshire, the Shetland Islands, and abundantly on the continent. It is employed for drawing lines by carpenters, tailors, hat-makers, and glaziers.

TALENT, money of account amongst the ancients. Amongst the Jews, a talent in weight was equal to sixty maneh, or 113 ℔. 10 oz. 1 dwt. 10¾ gr.

TALES, *i. e. tales de circumstantibus*, bystanders, is used in law, for a supply of men impannelled on a jury, and not appearing, or on their appearance challenged and disallowed, when the judge upon motion orders a supply to be made by the sheriff of one or more such persons as are present in court, to make up a full jury.

TALIO, *lex talionis*, a species of punishment in the Mosaic law, whereby an evil is returned similar to that committed against us by another; hence that expression, eye for eye, tooth for tooth.

TALLOW-TREE. See CROTON.

TALLY, in law, a piece of wood cut in two parts, whereon accounts were anciently kept, by means of notches; one part of the tally being kept by the debtor, and the other by the creditor.

TALMUD, or THALMUD, among the Jews, a collection of the doctrines of their religion or morality. It is the corpus juris, or body of the laws and customs of the Jews, who esteem it equal to the scriptures themselves.

TALPA, MOLE, a genus of the quadrupeds of the order feræ. The generic character is, front teeth in the upper jaw six, unequal; in the lower jaw eight; canine teeth, one on each side, the upper ones largest; grinders seven in the upper jaw, six in the lower.

1. *Talpa Europæa*, the common mole. The whole form of the mole is eminently calculated by nature for its obscure and subterraneous life. The body is thick and cylindric; the snout slender, but very strong and tendinous; the head not distinguished from the body by any appearance of neck; the legs so extremely short as scarcely to project perceptibly from the body; the skin is much thicker and tougher in proportion than in other quadrupeds, and the fur with which it is covered equally surpasses that of other animals in fineness and softness. The muscular strength of the mole is very great, and it is enabled to force itself into the ground with an extraordinary degree of celerity. The general length of the mole is about five inches and three quarters, exclusive of the tail, which measures one inch.

2. *Talpa radiata*, radiated mole. This is somewhat smaller than the common mole, and is of a dusky or blackish colour. In general form, it resembles the preceding species, having broad fore legs with long claws; the hind legs scaly and with much weaker claws; the nose long, and beset at the end with a circular series of radiated tendrils; the length from nose to tail is three inches and three quarrers. It is an inhabitant of North America.

TAMARINDUS, the *tamarind-tree*, a genus of plants arranged by Linnæus under the class of triandria and order of monogynia; but Woodville, Schreber, and other late botanists, have found that it belongs to the class of monadelphia, and order of triandria. In the natural system it is ranged under the lomantaceæ. There is only one species, Indica, which is a native of both Indies, of America, of Arabia, and of Egypt. The timber of the tamarind tree is heavy, firm, and hard; sawn into boards, it is converted to many useful purposes in building. The fruit is used both in food and medicine. In many parts of America, particularly in Curacao, they eat abundance of it raw, without any inconvenience. In Martinico also, they eat the unripe fruit, even of the most austere kind.

TANNIN. This, which is one of the immediate principles of vegetables, was first distinguished by Seguin from the gallic acid, with which it had been confounded under the name of the *astringent principle.* He gave it the name of tannin, from its use in the tanning of leather; which it effects by its characteristic property, that of forming with gelatin a tough insoluble matter.

It may be obtained from vegetables by macerating them in cold water; and precipitated from this solution, which contains likewise gallic acid and extractive matter, by hyperoxygenized muriate of tin.

TANNING. The several kinds of leather are prepared from the skins of animals macerated with lime and water, to promote the separation of the hair and wool, and of the fat and fleshy parts, in which recourse is also had to the assistance of mechanical pressure, scraping, and the like. The skin, when thus deprived of its more putrescible part, and brought considerably toward the state of mere fibre, is tanned by maceration with certain astringent substances, particularly the bark of the oak-tree

The hide consists almost wholly of gelatin and all that is necessary is, to divest it of the hair, epidermis, and any flesh or fat adhering to it. This is commonly done, after they have been soaked in water some time, and handled or trodden to cleanse them from filth, by immersing them in milk of lime. Some, instead of lime, use an acescent infusion of barley or rye-meal, or spent tan; and others recommend water acidulated with sulphuric acid. Similar acidulous waters are afterward employed for raising or swelling the hide, when this is necessary.

The skins, thus prepared, are finally to undergo what is properly called the tanning. This is usually done by throwing into a pit, or cistern made in the ground, a quantity of ground oak-bark, that has already been used, and on this the skins and fresh bark in alternate layers, covering the whole with half a foot of tan, and treading it well down. The tanning may be accelerated by adding a little water.

TANTALITE, in mineralogy, a metallic fossil of an iron black colour on the external surface, but internally between bluish-grey, and iron-black. It occurs imbedded, in masses of the size of a hazel nut, which have a tendency to the octahedral form.

TANTALIUM, a metal discovered by M. Ekeberg, in the mineral just mentioned; and in another named Ytrotantalite.

TANTALUS, or IBIS, a genus of birds of the order grallæ. The generic character is, bill long, subulate, roundish subarched; face naked; nostrils oval; feet four-toed, palmate at the base. There are 19 species.

TANTALUS'S CUP. See HYDRAULICS.

TAPE-*worm.* See TÆNIA.

TAPESTRY, a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, histories, &c.

TAPIR, a genus of quadrupeds of the order belluæ. The generic character is, front teeth in both jaws, ten; canine teeth in both jaws, single, incurvated: grinders in both jaws, five on each side, very broad; feet with three hoofs, and a false hoof on the fore feet.

TAR, a thick, black, unctuous substance, obtained from old pines and fir trees, by burning them with a close smothering heat: it is used for coating and caulking ships, &c. and various other purposes.

TARANTULA. See ARANEA.

TARE, is an allowance for the outside package, that contains such goods as cannot be unpacked without detriment, or for the papers, threads, bands, &c. that inclose or bind any goods imported loose; or, though imported in casks, chests, &c. yet cannot be unpacked and weighed net.

TARGUM, a name whereby the Jews call the Chaldee paraphrases, or expositions of the Old Testament, in the Chaldee language.

TARIF, or TARIFF, a table or catalogue, containing the names of different sorts of merchandize, with the duties to be paid, as settled by authority, amongst trading nations.

TARRAS, or TERRAS, a volcanic earth

used as a cement. It does not differ much in its principles from pouzzolana; but it is much more compact, hard, porous, and spongy. It is generally of a whitish-yellow colour, and contains more heterogeneous particles, as spar, quartz, schorl, &c. and something more of a calcareous earth. It effervesces with acids, is magnetic, and fusible *per se*. When pulverized, it serves as a cement, like pouzzolana. It is found in Germany and Sweden. See LIME.

TARTAR is deposited on the sides of casks during the fermentation of wine; it forms a lining more or less thick, which is scraped off. This is called crude tartar, and is sold in Languedoc from 10 to 15 livres the quintal.

Tartar is distinguished from its colour into red and white: the first is afforded by red wine.

Tartar is purified from an abundant extractive principle, by processes which are executed at Montpellier and at Venice.

The following is the process used at Montpellier:—The tartar is dissolved in water, and suffered to crystallize by cooling. The crystals are then boiled in another vessel, with the addition of five or six pounds of the white argillaceous earth of Murviel to each quintal of the salt. After this boiling with the earth, a very white salt is obtained by evaporation, which is known by the name of cream of tartar, or the acidulous tartrate of potash.

TARTARIC ACID. The casks in which some kinds of wine are kept become incrusted with a hard substance, tinged with the colouring matter of the wine, and otherwise impure, which has long been known by the name of *argal*, or tartar, and distinguished into red and white according to its colour. This being purified by solution, filtration, and crystallization, was termed *cream*, or *crystals of tartar*. It was afterwards discovered, that it consisted of a peculiar acid combined with potash; and the supposition that it was formed during the fermentation of the wine, was disproved by Boerhaave, Neuman, and others, who showed that it existed ready formed in the juice of the grape. It has likewise been found in other fruits, particularly before they are too ripe; and in the tamarind, sumac, balm, carduus benedictus, and the roots of rest-harrow, germander, and sage. The separation of tartaric acid from this acidulous salt, is the first discovery of Scheele that is known. He saturated the superfluous acid, by adding chalk to a solution of the super-tartrate in boiling water as long as any effervescence ensued, and expelled the acid from the precipitated tartrate of lime by means of the sulphuric. Or four parts of tartar may be boiled in twenty or twenty-four of water, and one part of sulphuric acid added gradually. By continuing the boiling, the sulphate of potash will fall down. When the liquor is reduced to one-half, it is to be filtered; and if any more sulphate be deposited by continuing the boiling, the filtering must be repeated. When no more is thrown down, the liquor is to be evaporated to the consistence of a syrup; and thus crystals of tartaric acid, equal to half the weight of the tartar employed, will be obtained.

TARTRATS, salts formed with the tartaric acid.

TAURUS. See ASTRONOMY.

TAX. See REVENUE, CUSTOMS, &c.

TAXUS, the YEW-TREE, a genus of plants of the class of diœcia, and order of monadelphia; and in the natural system ranging under the 51st order, coniferæ. There are four species; of which the baccata, or common yew-tree, is a native of Britain, France, Switzerland, &c. and of North America. It is distinguished from the other species by linear leaves which grow very close, and by the receptacles of the male flowers being subglobose. The wood is reddish, full of veins, and flexible, very hard and smooth, and almost incorruptible. Its hardness renders it very proper for turners and cabinet-makers.

TEARS, a name for the limpid fluid secreted by the lachrymal glands, and flowing on the surface of the eye; either in consequence of local irritation, or the emotions of grief.

The tears have no smell, but a saltish taste. The uses of the tears are these: 1. They continually moisten the surface of the eye and eyelids, to prevent the transparent cornea from drying and becoming opaque, or the eye from concreting with the eye-lids. 2. They prevent that pain which would otherwise arise from the friction of the eye-lids against the ball of the eye from continually winking. 3. They wash away dust, or any thing acrid, that may have fallen into the eye.

TEETH. The basis of the substance that forms the teeth, like that of other bones, (see BONE,) appears to be phosphate of lime. The enamel, however, according to Mr. Hatchett, differs from other bony substances in being destitute of cartilage: for raspings of enamel, when macerated in diluted acids, he found were wholly dissolved; while raspings of bone, treated in the same manner, always left a cartilaginous substance untouched.

TELEGRAPH, an instrument by means of which information may be quickly conveyed to a considerable distance. The telegraph is by no means a modern invention. There is reason to believe that amongst the Greeks there was some sort of telegraph in use. A Greek play begins with a scene, in which a watchman descends from the top of a tower in Greece, and gives the information that Troy was taken. "I have been looking out these ten years (says he) to see when that would happen, and this night it is done."

The telegraph however was not brought into general use till the French revolution.

TELESCOPE. See OPTICS.

TELLURIUM. See CHEMISTRY.

TEMPERAMENT, in music, the accommodation or adjustment of the imperfect sounds by transferring a part of their defects to the more perfect ones, in order to remedy, in some degree, the false intervals of those instruments, the sounds of which are fixed; as the organ, harpsichord, piano-forte, &c.

TEMPERATURE. See METEOROLOGY.

TEMPERING *of steel and iron*, the rendering of them either more compact and hard, or soft and pliant, according as the different uses for which they are wanted may require.

TEMPLARS, or TEMPLERS, a religious order instituted at Jerusalem, about the year 1118. Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. King Baldwin assigned them an apartment in his palace.

TENACITY. See COHESION.

TENAILLE, in fortification, a kind of outwork, resembling a hornwork, but generally somewhat different; for, instead of two demi-bastions, it bears only in front a re-entering angle between the same wings without flanks; and the sides are parallel.

TENANT, signifies one who holds or possesses lands or tenements by any kind of right, either in fee, for life, years, or at will.

TENCH. See CYPRINUS.

TENDER, in law, is an offer to pay a debt, perform a duty. This is often pleaded in action as a bar to the plaintiff's recovery; and where the money demanded by the plaintiff has been tendered or offered to him before the commencement of the suit, and he has refused to accept it, the plaintiff is barred of his action and costs.

TENDER, a small ship in the service of men of war, for carrying of men, provisions, or any thing else that is necessary.

TENDONS, are white, firm, and tenacious parts, continuous to the muscles, and usually forming their extremities.

TENEMENT, in its common acceptation, is applied only to houses and other buildings; but in its original, proper, and legal sense, it signifies every thing that may be holden, provided it be of a permanent nature, whether it be of a substantial or of an unsubstantial and ideal kind.

TENNIS, a play at which a ball is driven by a racket; this play is much in use in most of the capital cities of Europe.

TENON, in building, &c. the square end of a piece of wood, or metal, diminished by one-third of its thickness, to be received into a hole in another place, called a mortise, for jointing or fastening the two together. It is made in various forms, square, dove-tailed, for double mortises, &c.

TENOR, of writs, records, &c. is the substance or purport of them, or a transcript or copy.

TENOR, in music, the second of the four parts in harmonical composition, reckoning from the bass. The tenor is the part most accommodated to the common voice of man; from which circumstance it has sometimes, by way of preference, been called "the human voice." Its general compass extends from C above G gamut to G the treble-cliff note.

TENOR-*cliff*, the name given to the C cliff, when placed on the fourth line of the stave.

TENOR VIOLIN, or *Viola*, a stringed instrument resembling the violin, but lower in its scale, having its lowest note in C above G gamut. In concert this instrument takes the part next above the bass.

TENSE, *time*, in grammar, an inflection of verbs, whereby they are made to signify or distinguish the circumstance of time, in what they affirm.

TENSION, the state of a thing stretched. Thus animals sustain and move themselves by the tension of their muscles and nerves. A chord or string gives an acuter or deeper sound, as it is in a greater or less degree of tension, that is, more or less stretched or tightened.

TENTER, a railing used in the cloth-manufacture, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square. It is usually about four feet and a half high, and for length exceeds that of the longest piece of cloth.

TENURE, the manner whereby lands or tenements are holden, or the service that the tenant owes to his lord.

TEREBELLA, a genus of vermes mollusca. The generic character is, body oblong, creeping, naked, often enclosed in a tube furnished with lateral tufts and branchiæ; mouth placed before, furnished with lips, without teeth, and protending a clavate proboscis; feelers numerous, ciliate, capillary, seated round the mouth.

TEREDO, in natural history, a genus of vermes belonging to the order of testacea. The animal is a terebella; there are two valves, calcareous, hemispherical, and cut off before and two lanceolated. The shell is tapering, bending, and capable of penetrating wood.

TERM, in geometry, is the extreme of any magnitude, or that which bounds and limits its extent.

TERMS, of an equation, or of any quantity, in algebra, are the several numbers of which it is composed separated from one another by the signs + or −. So, the quantity $ax + 2bc - 3ax^2$, consists of the three terms ax and $2bc$ and $3ax^2$.

TERMS, are those spaces of time wherein the courts of justice are open for all that complain of wrongs or injuries, and seek their rights by course of law or action in order to their redress; and during which, the courts in Westminster Hall sit and give judgments, &c. but the high court of parliament, the chancery and inferior courts, do not observe the terms; only the courts of king's bench, common-pleas, and exchequer, the highest courts at common law. Of these terms there are four in every year, viz. Hilary term, which begins the 23d of January, and ends the 12th of February, unless on Sundays, and the day after; Easter term, which begins the Wednesday fortnight after Easter-day, and ends the Monday next after ascension day; Trinity term, which begins the Friday after Trinity Sunday, and ends the Wednesday fortnight after; and Michaelmas term begins the 6th and ends the 28th of November.

TERMS, *Irish*, are the same as those in London, except that at Michaelmas, which commences October 13, and adjourns to the beginning of November.

TERMS, *Cambridge*. Lent term begins on Jan. 13. and ends the Friday before Palm Sunday. Easter term begins the Wednesday after Easter week, and ends the week before Whit-Sunday. Trinity term begins the Wednesday after Trinity Sunday, and ends the Friday after the commencement. Michaelmas term begins Oct. 10, and ends Dec. 16.

TERMS, *Oxford*. Hilary, or Lent term, begins on Jan. 14, and ends the Saturday before Palm Sunday. Easter term begins the tenth day after Easter, and ends the Thursday before Whit-Sunday. Trinity term begins the Wednesday after Trinity Sunday, and ends after the act, sooner or later, as the vice-chancellor and convocation please. Michaelmas term begins on Oct. 10, and ends Dec. 17.

TERMS, *Scottish*. In Scotland, Candlemas term begins Jan. 23, and ends Feb. 12. Whitsuntide term begins May 25, and ends June 15 Lammas term begins July 30, and ends Aug. 8.

Martinmas terms begins Nov. 3, and ends Nov. 29.

TERMES, *the white ant*, a genus of insects of the order aptera: the generic character is, legs six, formed for running; eyes two; antennæ setaceous; mouth furnished with two jaws. There are ten species, in two sections: A. antennæ moniliform; B. antennæ setaceous.

T. *fatale*, or white ant, is brown above; thorax with three segments; wings pale with a testaceous rib. A most curious account of this insect is given in the Philosophical Transactions, of which we shall notice a few particulars. The animals of this extraordinary community, far exceeding in wisdom and policy the bee, the ant, or beaver, are inhabitants of East India, Africa, and South America. They build pyramidal structures ten or twelve feet in height, and divided into appropriate apartments, magazines for provisions, arched chambers, and galleries of communication. These are so firmly cemented that they easily bear four men to stand upon them, and in the plains of Senegal appear like the villages of the natives. With such wonderful dexterity and rapidity they destroy food, furniture, books, clothes, and timber of whatever magnitude, leaving a mere thin surface; that in a few hours a large beam will be eaten to a mere shell not thicker than writing paper. Larva small, about a quarter of an inch long: six-footed, pale with a roundish testaceous head; eyes none; mandibles short, strong, and toothed; antennæ as long as the thorax, and ovate abdomen. These only are the labourers, who build the structures, procure provisions for the males and females, and take care of the eggs: they are the most numerous. Pupa larger, about half an inch long, with a very large ovate polished testaceous head; eyes none; mandibles projecting, as long as the head, forked, without teeth, sharp and black; thorax and abdomen palish. These never work, but act as superintendants over the labourers, or as guards to defend their habitations from intrusion and violence. When a breach is made in the dwelling, they rush forward, and defend the entrance with great ferocity; some of them beating with their mandibles against any hard substance, as a signal to the other guards, or as encouragement to the labourers; they then retire, and are succeeded by the labourers, each with a burthen of tempered mortar in his mouth, and who diligently set about to repair whatever injury has been sustained. One of these attends every six or eight hundred labourers, who are building a wall, taking no active part himself, but frequently making the noise above mentioned, which is constantly answered by a loud hiss from all the labourers, who at this signal evidently redouble their diligence.

TERMINATOR, in astronomy, a name sometimes given to the circle of illumination, from its property of terminating the boundaries of light and darkness. This line will, of course, pass through the poles of the earth at the equinoxes.

TERRIER, a book or roll, wherein the several lands, either of a private person, or of a town, college, church, &c. are described.

TESSELLATED PAVEMENTS, those of rich mosaic work, made of curious squares marbles, bricks, or tiles, called *tesselæ*, from their resembling dice.

TEST, a vessel used in metallurgy for absorbing the scoriæ of metallic bodies when melted.

* **TEST-ACT.** A statute 25 Car. II, cap. 2. which requires all officers, both civil and military, to take the oaths and test, viz. the sacrament, according to the rites and ceremonies of the church of England. Various ineffectual attempts have been made by the dissenters to obtain the repeal of this act, which is evidently offensive to the genuine principles of civil and religious liberty. Its natural and unavoidable tendency is to increase the number of hypocrites in the country; and to keep conscientious men out of those situations in which they are so much wanted.

TESTACEA, in the Linnæan system of natural history, the third order of vermes. This order comprehends all shell-fish, arranged by Linnæus under thirty-six genera. Shell-fish are animals with a soft body, covered by or inclosed in a firm, hard, and stony habitation, composed according to their three separate orders.

TESTAMENT, in law, a solemn and authentic act, whereby a person declares his will, as to the disposal of his estates, effects, burial, &c. See WILL.

TESTUDO, the *tortoise*, in natural history, a genus of amphibia of the order reptiles. Generic character: body tailed, covered above and beneath, defended by a bony covering, covered by a horny, scaly, or coriaceous integument; a bony mouth, without distinct teeth, and the upper mandible closing over the lower. These animals feed on sea-weeds or on worms, are extremely prolific; but in the state of eggs, and while very young, are the prey of various animals. Their movements are slow, they are capable of being tamed, and will in that state eat almost any thing presented to them. They exist long in such air as would be destructive to other animals of the same size, and have such tenaciousness of life, that it is stated they will exhibit convulsive movements for several days after their bodies have been opened, and even after their heads have been cut off. In cold latitudes the land tortoise is torpid during the winter. There are thirty-five species, of which the principal is, the testudo græca, or the common tortoise. The weight of this animal is three pounds, and the length of its shell about seven inches. It abounds in the countries surrounding the Mediterranean, and particularly in Greece, where the inhabitants not only eat its flesh and eggs, but frequently swallow its warm blood. In September or October it conceals itself, remaining torpid till February, when it re-appears. In June it lays its eggs, in holes exposed to the full beams of the sun, by which they are matured. The males will frequently engage in severe conflicts, and strike their heads against each other with great violence, and very loud sounds. Tortoises attain most extraordinary longevity, and one was ascertained to have lived in the gardens of Lambeth to the age of nearly 120 years. Its shell is preserved in the archiepiscopal palace. So reluctant is the vital principle to quit these animals, that Shaw informs us, from Redi, one

of them lived for six months after all its brain was taken out, moving its limbs, and walking as before.

TESTUDO, in the military art of the ancients, was a kind of cover or screen which the soldiers, *e. gr.* a whole company made themselves of their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

TESTUDO was also a kind of large wooden tower which moved on several wheels, and was covered with bullocks' hides, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

TETRACHORD, in the ancient music, a concord consisting of four degrees or intervals, and four terms or sounds; called also by the ancients diatessarron, and by us a fourth.

TETRADYNAMIA (τεσσαρες, *four*, and δυναμις, *power*,) four powers; the name of the 15th class in Linnæus's sexual system.

TETRAGYNIA (τεσσαρες, *four*, and γυνη, a *woman*,) the name of an order, or secondary division, in the 4th, 5th, 6th, 8th, and 13th classes in the sexual system.

TETRANDRIA (τεσσαρες, *four*, and ανηρ, a *man* or *husband*,) the name of the fourth class in Linnæus's sexual system.

TETRAO, in ornithology, a genus of birds belonging to the order of gallinæ, and thus characterised by Linnæus: there is a spot near the eyes naked or papillose, or covered, though more rarely, with feathers. There are venty-three species, of which the following are best deserving of notice:

T. *urogallus*, or the cock of the wood, is of the size of a turkey, and is found from Russia to Italy, preferring the elevated and mountainous parts of temperate countries, as it delights in a cold temperature. Its eggs are deposited on moss, and whenever left by the female, who is unassisted in the process of incubation, are covered over with leaves. The males and females live separate, except during the months of February and March. Their food consists of various plants and grains, and of buds of trees. The seeds of the pine and fir they are particularly fond of.

T. *tetrix*, or the black grouse, is larger than a common fowl, and abounds in the British islands, particularly in the northern districts. The birds of this species, and of the last, do not pair like other birds, and the male is generally seen with several females in his train. They subsist on seeds and herbage, and are particularly fond of the seeds of the birch and Siberian poplar.

T. *lagopus*, or the ptarmigan grouse, is fourteen inches long, and inhabits the north of Europe. It is not uncommon in the Orknies and the Hebrides, and is sometimes found in Cumberland. These birds subsist on seeds, fruits, and berries, and are like the last, silly and inadvertent to danger.

T. *perdrix*, the common partridge, is about nineteen inches long, and is principally found in the temperate regions of Europe; in England it is a favourite delicacy at the tables of the rich. The manners of the partridge much resemble those of poultry in general.

T. *coturnix*, or the quail, is between seven and eight inches long, and inhabits almost every country of the old world, but is not found in America. It is migratory, and moves in spring towards the colder climates, returning southerly in autumn. In these progresses quails fly in immense multitudes, and are taken in the islands of the Archipelago in such numbers as for a short time to be the principal article of food for the inhabitants, and to constitute an important source of income and revenue. Within a few miles, along the coasts of Italy, a hundred thousand are said to have been taken in a single day.

TEUTONIC ORDER, a military order of knights, established towards the close of the twelfth century, and thus called as consisting chiefly of Germans or Teutons. The origin, &c. of the Teutonic order is said to be this: The Christians, under Guy of Lusignan, laying siege to Acre, a city of Syria, on the borders of the Holy Land, some Germans of Bremen and Lubec, touched with compassion for the sick and wounded of the army, who wanted common necessaries, set on foot a kind of hospital under a tent, which they made of a ship's sail, and here betook themselves to a charitable attendance on them. This excited a thought of establishing a third military order, in imitation of the templars and hospitalers. The design was approved of by the patriarch of Jerusalem, the archbishops and bishops of the neighbouring places, the king of Jerusalem, the masters of the temple and hospital, and the German lords and prelates then in the Holy Land, and pope Calixtus III. confirmed it by his bull, and the new order was called the order of Teutonic knights of the house of St. Mary at Jerusalem.

TEXT, a relative term, contradistinguished to gloss or commentary, and signifying an original discourse exclusive of any note or interpretation. This word is particularly used for a certain passage of scripture, chosen by a preacher to be the subject of his sermon.

THALLITE, a stone found in the fissures of mountains in Dauphiny, and on Chamouni, in the Alps. It is sometimes amorphous, and sometimes crystallized. The primitive form of its crystals is a rectangular prism, whose bases are rhombs with angles of 114 deg. 37 min. and 65 deg. 23 min. The most usual variety is an elongated four-sided prism, (often flattened) terminated by four-sided incomplete pyramids; sometimes it occurs in regular six-sided prisms. The crystals are often very slender. Its texture appears fibrous. Lustre 2. Glassy. Causes single refraction. Brittle. Specific gravity 3.45 to 3.46. Colour dark green. Powder white or yellowish green, and feels dry. It does not become electric by heat. Before the blowpipe, froths, and melts into a black slag. With borax melts into a green bead.

THEA, the *tea-tree*, in botany, a genus of the class and order polyandria monogynia. The corolla is six or nine-petalled; the calyx five or six-leaved; the capsule tricoccous. There are two species, or at least principal varieties; the viridis or green, and the bohea, which again admit of various subdivisions or varieties.

The tea plant is a native of Japan, China, and Tonquin, and has not been found growing spontaneously in any other part of the world. This plant delights in valleys, and is frequent on the sloping sides of mountains and the

banks of rivers, where it enjoys a southern exposure. It flourishes in the northern latitudes of Pekin as well as round Canton; but attains the greatest perfection in the mild temperate regions of Nankin. In this country teas are generally divided into three kinds of green, and five of bohea: the former are, 1. Imperial, or bloom tea, with a large loose leaf, light green colour, and a faint delicate smell. 2. Hyson, so called from the name of the merchant who first imported it; the leaves of which are closely curled and small, of a green colour, verging to a blue. 3. Singlo tea, from the name of the place where it is cultivated. The boheas are, 1. Souchong, which imparts a yellow-green colour by infusion. 2. Camho, so called from the place where it is made; a fragrant tea, with a violet smell; its infusion pale. 3. Congo, which has a larger leaf than the preceding, and ts infusion somewhat deeper, resembling common bohea in the colour of the leaf. 4. Pekoe

white flowers mixed with it. 5. Common bohea, whose leaves are of one colour. There are other varieties, particularly a kind of green tea, done up in roundish balls, called gunpowder tea.

THEFT, in law, an unlawful felonious taking away another man's moveable and personal goods against the owner's will, with intent to steal them. It is divided into theft or larceny, properly so called, and petit theft, or petit larceny; the former whereof is of goods above the value of 12*d.* and is deemed felony; the other, which is of goods under that value, is not felony.

THEODOLITE, a mathematical instrument much used in surveying, for the taking of angles, distances, &c.

THEOREM, a proposition which terminates in theory, and which considers the properties of things already made or done. Or a theorem is a speculative proposition, deduced from several definitions compared together.

THERMOMETER. An instrument for measuring heat, founded on the principle, that the expansions of matter are proportional to the augmentations of temperature. A common thermometer, therefore, is merely a vessel in which very minute expansions of mercury may be rendered perceptible; and, by certain rules of graduation, be compared with expansions made on the same liquid, by other observers.

Air is the most expansible fluid, but it does not receive nor part with its heat so quickly as mercury. Alcohol does not expand much by heat. In its ordinary state it does not bear a much greater heat than 175° of Fahrenheit; but when highly rectified it can bear a greater degree of cold than any other liquor hitherto employed as a measure of temperature. At Hudson's Bay, Mr. Macnab, by a mixture of vitriolic acid and snow, made it to descend to 69° below 0 of Fahrenheit. There is an inconvenience, however, attending the use of this liquor; it is not possible to get it always of the same degree of strength. As to oil, its expansion is about 15 times greater than that of alcohol; it sustains a heat of 600°, and its freezing point is so low that it has not been determined; but its viscosity renders it useless.

Mercury is far superior to alcohol and oil, and is much more manageable than air. 1. As far as the experiments already made can determine, it is of all the fluids hitherto employed in the construction of thermometers, that which measures most exactly equal differences of heat by equal differences of its bulk: its dilatations are, in fact, very nearly proportional to the augmentations of heat applied to it. 2. Of all liquids it is the most easily freed from air. 3. It is fitted to measure high degrees of heat and cold. It sustains a heat of 600° of Fahrenheit's scale, and does not congeal till it fall 39 or 40 degrees below 0. 4. It is the most sensible of any fluid to heat and cold, even air not excepted. Count Rumford found, that mercury was heated from the freezing to the boiling point in 58 seconds, while water took 2 minutes 13 seconds, and common air 10 minutes and 17 seconds. 5. Mercury is a homogeneous fluid, and every portion of it is equally dilated or contracted by equal variations of heat. Any one thermometer, made of pure mercury, is *cæteris paribus*, possessed of the same properties with every other thermo-

of pure mercury. Its pov

expansion is indeed about six times less than that of spirit of wine, but it is great enough to answer most of the purposes for which a thermometer is wanted. The fixed points, which are now universally chosen for adjusting thermometers to a scale, and to one another, are the boiling and freezing water points. In order to ensure uniformity, therefore, in the construction of thermometers, it is now agreed, that the bulb of the tube be plunged in the water when it boils violently, the barometer standing at 30 English inches, and the temperature of the atmosphere 55 degrees.

As artists may be often obliged to adjust thermometers under very different pressures of the atmosphere, philosophers have been at pains to discover a general rule which might be applied on all occasions.

1. To convert the degrees of Reaumur into those of Fahrenheit; $\frac{R\times9}{4}+32=F$.

2. To convert the degrees of Fahrenheit into those of Reaumur; $\frac{(F-32)\times4}{9}=R$.

To such readers as are unacquainted with the algebraic expression of arithmetical formulæ, it will be sufficient to express one or two of these in words to explain their use: 1. Multiply the degree of Reaumur by 9, divide the product by 4, and to the quotient add 32, the sum expresses the degree of the scale of Fahrenheit. 2. From the degree of Fahrenheit subtract 32, multiply the remainder by 4, and divide the product by nine, the quotient is the degree according to the scale of Reaumur, &c.

Thermometers have been made of a great variety of shapes and sizes.

The most common form is represented by Fig. 3, plate XXXIV. This figure shows merely the tube and index-plate; these are fitted up in cases of various kinds, according to the purpose for which they are wanted.

The common contrivance for a self-registering thermometer, now sold in most of the London shops, consists simply of two thermometers, one mercurial, and the other of alcohol, Fig. 4. having their stems horizontal; the former has for its index a small bit of magnetical steel wire, and the latter a minute thread of glass, having its two ends formed into small knobs, by fusion in the flame of a candle.

The magnetical bit of wire lies in the vacant space of the mercurial thermometer, and is pushed forward by the mercury whenever the temperature rises, and pushes that fluid against it; but when the temperature falls, and the fluid retires, this index is left behind, and consequently shows the maximum. The other index, or bit of glass, lies in the tube of the spirit thermometer immersed in the alcohol; and when the spirit retires, by depression of temperature, the index is carried along with it, in apparent contact with its interior surface; but, on increase of temperature, the spirit goes forward and leaves the index, which therefore shows the minimum of temperature since it was set. As these indexes merely lie in the tubes, their resistance to motion is altogether inconsiderable. The steel index is brought to the mercury by applying a magnet on the outside of the tube, and the other is duly placed at the end of the column of alcohol, by inclining the whole instrument.

THORACIC, a term applied to an order of fishes in the Linnæan system; the character of this order of fishes is, that they have bony gills, and ventral fins placed directly under the thorax.

THRASHING or *Threshing*, in agriculture, the art of beating the corn out of the ears.

THRAVE, or *Threave of corn*, twenty-four sheaves, or four shocks of six sheaves to the shock, though in some counties, they only reckon twelve shocks to the thrave.

THREAD, a small line made up of a number of fine fibres of any vegetable or animal substance, such as flax, cotton, or silk; from which it takes its name of linen, cotton, or silk thread.

THREATENING LETTER. See LETTERS.

THRUSH. See TURDUS.

THUMERSTONE. See MINERALOGY.

THUNDER, the noise occasioned by the explosion of a flash of lightning passing through the air: or it is that noise which is excited by a sudden explosion of electrical clouds, which are therefore called thunder clouds.

The rattling in the noise of thunder, which makes it seem as if it passed through arches, is probably owing to the sound being excited among clouds hanging over one another, and the agitated air passing irregularly between them.

THYMUS, THYME, a genus of plants of the class didynamia, and order gymnospermia; and in the natural system ranging under the 42d order, verticillatæ. The calyx is bilabiate, and its throat closed with soft hairs. There are 22 species; of which only two are natives of Britain, the serpyllum and acinos.

TIDES. See ASTRONOMY.

TIERCE, or TERCE, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons. See MEASURE.

TIGER. See FELIS.

TIGERSHELL, a beautiful species of voluta, of a dusky-red colour, spotted all over with large irregular blotches of white: it is brought from the East Indies, and is about two inches and a half in length, and about an inch in diameter.

TILE, in building, a sort of thin brick, used on the roofs of houses; or more properly a kind of clayey earth, kneaded and moulded of a just thickness, dried and burned in a kiln, like a brick and used in the covering and paving of different kinds of military and other buildings.

TILLER *of a ship* a strong piece of wood fastened in the head of the rudder, and in smal ships and boats called the helm.

TIMBER, includes all kinds of felled and seasoned woods. Of all the different kinds known in Europe, oak is the best for building and even when it lies exposed to air and water, there is none equal to it. Fir-timber is however perhaps more generally useful than any other. It is used for flooring, wainscoting, and the ornamental parts of building within doors. Elm is the next in use, especially in England and France; it is very tough and pliable, and therefore easily worked; it does not readily split, and it bears driving of bolts and nails better than any other wood. Ash is chiefly used by wheelrights, and coachmakers, for shafts, naves, &c. Beech is also used for many purposes; it is very tough and white when young, and of great strength, but liable to warp very much when exposed to the weather, and to be worm-eaten when used within doors; its greatest use is for planks, bedsteads, chairs, and other household goods.

The goodness of timber not only depends on the soil and situation on which it stands, but likewise on the season wherein it is felled. In this, people disagree very much; some are for having it felled as soon as its fruit is ripe, others in the spring, and many in the autumn. But as the sap and moisture of timber is certainly the cause that it perishes much sooner than it otherwise would do, it seems evident that timber should be felled when there is the least sap in it, viz. from the time that the leaves begin to fall, till the trees begin to bud. This work usually commences about the end of April in England, because the bark then rises most freely; for where a quantity of timber is to be felled, the statute requires it to be done then, for the advantage of tanning.

After timber has been felled and sawed, it must be seasoned; for which purpose some advise it to be laid up in a very dry airy place, yet out of the wind and sun, or at least free from the extremities of either; and that it may not decay, but dry evenly, they recommend it to be daubed over with cow-dung. It must not stand upright, but lie all along, one piece over another; only kept apart by short blocks, interposed to prevent a certain mouldiness, which they otherwise are apt to contract in sweating on one another; from which arises frequently a kind of fungus, especially if there be any sappy parts remaining. Others advise the planks of timber to be laid for a few days in some pool or running stream, in order to extract the sap, and afterwards to dry them in the sun or air. By this means, it is said, they will be prevented from either chopping, casting, or cleaving, but against shrinking there is no remedy.

TIMBER-TREES, in law, are properly oak, ash, and elm. In some particular countries, by local custom, other trees, being commonly there made use of for building, are considered as timber. Of these, being part of the freehold, larceny cannot be committed; but, if they be severed at one time, and carried away at another, then the stealing of them is larceny

And by several late statutes, the stealing of them in the first instance is made felony, or incurs a pecuniary forfeiture. For the better preservation of roots, shrubs, and plants, it is enacted by 6 George III. c. 48, that every person convicted of damaging, destroying, or carrying away any timber-tree, or trees, or trees likely to become timber, without consent of the owner, &c. shall forfeit for the first offence not exceeding £20, with the charges attending; and on non-payment shall be committed for not more than twelve, nor less than six months; for the second offence, a sum not exceeding £30, and on non-payment shall be committed for not more than eighteen, and not less than twelve months; and for the third offence, is to be transported for seven years. All oak, beech, chesnut, walnut, ash, elm, cedar, fir, asp, lime, sycamore, and birch-trees, shall be deemed and taken to be timber trees, within the true meaning and provision of this act.

TIME, a succession of phenomena in the universe; or a mode of duration, marked by certain periods or measures, chiefly by the motion and revolution of the sun. The idea of time, in general, Mr. Locke observes, we acquire by considering any part of infinite duration as set out by periodical measures: the idea of any particular time, or length of duration, as a day, an hour, &c. we acquire first, by observing certain appearances at regular, and, seemingly, at equidistant periods.

Time, *astronomical*, is that taken purely from the motion of the heavenly bodies, without any other regard.

Time, *civil*, is the former time accommodated to civil uses, and formed and distinguished into years, months, days, &c.

Time, in music, is an affection of sound, whereby we denominate it long or short, with regard to its continuance in the same degree of time.

TIN. See Chemistry.

TINNING. Tin combines with iron, and adheres strongly to its surface, forming a thin covering. This is one of the most useful combinations of tin, for it renders the iron fit for a great many valuable purposes, for which, otherwise, on account of its strong tendency to oxidation, or rusting, it would be totally inapplicable. This is well known by the name of tin-plate, or white iron. The process of tinning iron is the following: the plates of iron being reduced to the proper thickness, are cleaned by means of a weak acid. For this purpose the surface is first cleaned with sand, to remove any rust that may have formed. They are then immersed in water, acidulated with a small quantity of sulphuric acid, in which they are kept for twenty-four hours, and occasionally agitated. They are then well rubbed with cloths, that the surface may be perfectly clean. The tin is fused in a pot, the surface of which is covered with an oily or resinous matter, to prevent its oxidation.

The plates of iron are then immersed in the melted tin, and are either moved about in the liquid metal, or are dipped several different times. They are then taken out, and rubbed with saw-dust or bran, to remove the impurities from the surface.

TITANIUM. See Chemistry.

TITHES, are the tenth part of the increase yearly arising and renewing from the profits of lands, the stock upon lands, and the personal industry of the inhabitants. And hence they are usually divided into three kinds, prædial, mixed, and personal.

TITLE, in law, denotes any right which a person has to the possession of a thing; or an authentic instrument, whereby he can prove his right.

TOBACCO, in botany, a genus of the pentandria monogynia class and order. Natural order of Luridæ. Essential character, corolla funnel-form, with a plaited border; stamina inclined; capsule two-valved, two-celled. There are seven species, of which N. rustica. English tobacco seldom rises more than three feet in height, having smooth alternate leaves upon short foot-stalks, flowers in small loose branches on the tops of the stalks of a yellow colour, appearing in July, which are succeeded by roundish capsules, ripening in the autumn. Sir Walter Raleigh, on his return from America, is said to have first introduced the smoking of tobacco into England. In the house in which he lived at Islington, are his arms, with a tobacco plant on the top of the shield. It is remarkable that tobacco has prevailed over the original name, petum, in all the European languages, with very little variation, and even in Tartary and Japan. Tobacco is derived from the island Tobago. Petum is the Brazilian name.

TODUS, the *tody*, in ornithology, a genus belonging to the order of picæ. The beak is slender, depressed, broad, and the base beset with bristles; the nostrils are small and oval; the toes are placed three before and one behind; the middle are connected to the outer. There are 15 species, according to Dr. Latham.

TOLUIFERA, the *balsam* of *tolu-tree*, a genus of plants of the class decandria, and order monogynia. The calyx is five-toothed, bell-shaped; petals five, obcordate; style none. There is only one species, the balsamum.

This balsam possesses the same general virtues with the balsam of Gilead, and that of Peru. It is, however, less heating and stimulating, and may, therefore, be employed with more safety. It has been chiefly used as a pectoral, and is said to be an efficacious corroborant in gleets and seminal weaknesses. It is directed by the Pharmacopœias in the syrupus tolutanus, tinctura tolutana, and syrupus balsamicus.

TOMBAC, a metal composed of copper and arsenic. See Arsenic.

TON WEIGHT, 20 hundred

TONE, or *Tune*, in music, a property of sound whereby it comes under the relation of grave and acute; or it is the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of sonorous bodies.

TONNAGE, a custom or impost due for merchandize brought or carried in tons from or to other nations after a certain rate in every ton.

TONTINE, a species of increasing annuity on which money is sometimes borrowed, either for the service of the state, or for erecting bridges, churches, theatres, taverns, and other expensive buildings. It is usually divided into a certain number of shares, for each of which a

life is nominated, and a certain annual sum being set apart for payment of interest on the money advanced, the same sum is to continue to be annually divided among the surviving nominees, by which means their annuities increase as the number of shares are reduced, till the whole are extinct.

TOP-*nautical*, an instrument to serve instead of the common artificial horizon used at sea for astronomical observations. The idea, we believe, originated with Mr. Serson, who was lost on-board of his Majesty's ship Victory about the middle of the last century. He observed, that when a top was spun, its upper surface directed itself, in the course of two minutes after it was set up, in a truly horizontal plane; and that this plane was not at all disturbed by any motion or inclination of the box on which it was placed; from which he inferred that it might be used advantageously as an artificial horizon. The ingenious Mr. Troughton has recently taken up the idea which had been long abandoned, and has brought the instrument to a great degree of perfection. It consists of a brass cylinder open at bottom, and terminated at the top by a circle of dark glass; the diameter about four inches, and the depth about 1½ inch. The newest form, however, is that of an inverted frustum of a cone; the base or lower surface about four inches, its height about 2½ inches; and the upper surface about six inches in diameter. The reflecting plane rests on a steel cup, half an inch wide, and on a steel point, which descends about half an inch below the upper surface of the frustum. To this beautiful contrivance motion is communicated by a train of wheel work. When the velocity is considered sufficient, the top is suddenly disengaged from the wheel work, and revolves alone with a velocity which has been calculated to be about 30 miles an hour. While thus revolving, the images of the objects reflected from the plate of glass appear to be absolutely fixed.

TOPAZ. See MINERALOGY.

TOPOGRAPHY, a description or draught of some particular place, or small tract of land, as that of a city or town, manor or tenement, field, garden, house, castle, &c. such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TORNADO, a sudden and vehement gust of wind from all points of the compass, frequent on the coast of Guinea.

A tornado seems to partake much of the nature of a whirlwind, or perhaps of a water-spout, but is more violent in its effects. It commences very suddenly, several clouds being previously drawn together, when a spout of wind, proceeding from them, strikes the ground, in a round spot of a few rods or perches diameter, and proceeds thus half a mile or a mile. The proneness of its descent makes it rebound from the earth, throwing such things as are moveable before it, but some sideways or in a lateral direction from it. A vapour, mist, or rain, descends with it, by which the path of it is marked with wet. The following is a description of one which happened a few years since at Leicester, about fifty miles from Boston, in New England: it happened in July, on a hot day, about four o'clock in the afternoon. A few clouds having gathered westward, and coming overhead, a sudden motion of their running together in a point being observed, immediately a spout of wind struck the ground at the west of a house, and instantly carried it away, with a negro man in it, who was afterwards found dead in the path of it. Two men and a woman, by the breach of the floor, fell into the cellar; and one man was driven forcibly up into the chimney-corner. These were preserved, though much bruised: they were met with a vapour or mist, as were the remains of the floor, and the whole path of the spout. This wind raised boards, timbers, &c. A joist was found on one end, driven nearly three feet into the ground. The spout probably took it in its elevated state, and drove it forcibly down. The tornado moved with the celerity of a middling wind, and constantly declined in strength till it entirely ceased.

TORPEDO. See RAY.

TORTOISE-SHELL, the shell of the testaceous animal called a tortoise; used in inlaying, and in various other works, as for snuff-boxes, combs, &c.

TOUCH, or FEELING, *sense of.* The sense of feeling differs from the other senses in belonging to every part of the body, external or internal, to which nerves are distributed. The term touch is most correctly applied to the sensibility which is diffused over the surface of the body. Touch exists with the most exquisite degree of sensibility at the extremities of the fingers and thumbs, and in the lips. The sense of touch is thus very commodiously disposed for the purpose of encompassing smaller bodies, and for adapting itself to the inequalities of larger ones.

The sensations acquired by the sense of feeling are those of heat, hardness, solidity, roughness, dryness, motion, distance, figures, &c. and all those corporeal feelings which arise from a healthy or diseased state of the nerves, and the part of the body to which they belong.

The pains of this sense are more numerous and vivid than those derived from any other sense; and therefore the relicts of them coalescing with one another, constitute the greatest share of our mental pains, that is, pains not immediately derived from sensation. On the other hand, its pleasures being faint and rare, in comparison with others, and particularly those of the taste, have but a small share in the formation of the mental pleasures.

TOUCH-NEEDLE, among assayers, refiners, &c. little bars of gold, silver, and copper, combined together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touchstone, with those of the bars.

TOURMALINE. See MINERALOGY.

TOURNEQUET, in surgery, an instrument made of rollers, compresses, screws, &c. for compressing any wounded part, so as to stop hæmorrhages.

TOW *to*, in naval affairs, is to draw a ship, or boat, forward in the water, by means of a rope attached to another vessel or boat, which advances by the effort of rowing or sailing.

TOWER, any high building raised above another, consisting of several stories, usually of a round form, though sometimes square or polygonal; a fortress, a citadel. Towers are built

for fortresses, prisons, &c. as the tower of the Bastile, which was destroyed by the inhabitants of Paris in 1789.

TRACHINUS, Weever, a genus of fishes of the order jugulares: the generic character is, head slightly roughened, compressed; gill-membrane six-rayed; gill-covers serrated on the edge; body compressed, vent situated near the breast.

TRADE, the practice of exchanging goods, wares, money, bills and other articles of value, with the view of advantage or profit. It is generally distinguished into foreign trade, or the export and import of commodities to and from other countries, and the internal or home trade, or that which is carried on within the country, which two branches, however, are rather distinct in appearance than reality; for a very considerable portion of the internal trade, arising from manufactures carried on to supply foreign markets, could not subsist without foreign commerce, while a large part of the returns for manufactures sent abroad being articles for consumption, or raw materials which are converted to use in the different manufactures, depends upon our internal trade, so that the one supports the other, and by their mutual connection and dependence, the foreign and the domestic trade of Great Britain have risen together to their present unparalleled height.

TRAGACANTH. This substance, which is vulgarly called gum-dragon, exudes from a prickly bush, the *astragalus tragacantha*, Linn. which grows wild in the warmer climates, and endures the cold of our own, but does not here yield any gum. This commodity is brought chiefly from Turkey, in irregular lumps, or long vermicular pieces bent into a variety of shapes: the best sort is white, semitransparent, dry, yet somewhat soft to the touch.

Tragacanth is usually preferred to the other gums for making up troches, and other like purposes, and is supposed likewise to be the most effectual as a medicine; but on account of its imperfect solubility, is unfit for liquid forms. It is commonly given in powder with the addition of other materials of similar intention; thus, to one part of gum-tragacanth are added one of gum-arabic, one of starch, and six of sugar.

TRAGEDY, a drama which represents some grand and serious action, and which has frequently a fatal issue or end. Its genuine object is to purify and moderate the passions, by exhibiting them in their excess, and to hold forth such a picture of the crimes and miseries of mankind as may teach us, by fear, to be prudent, for our own sake; and, by compassion, to be charitable, for the sake of others.

TRAJECTORY, a term often used, generally for the path of any body moving either in a void, or in a medium that resists its motion; or even for any curve passing through a given number of points.

TRAMMELS, in mechanics, an instrument used by artificers for drawing ovals upon boards, &c. One part of it consists of a cross with two grooves at right angles; the other is a beam carrying two pins which slide in those grooves, and also the describing pencils.

TRANSCENDENTAL or **Transcendant**, something elevated or raised above other things, which passes and transcends the nature of other inferior things.

The term has been ostentatiously applied to the metaphysical speculations of Kant, hence called the transcendental philosophy; but with what degree of propriety this assumption is made, remains to be proved.

TRANSIT, in astronomy, signifies the passage of any planet, just by or over a fixed star, or the sun; and of the moon in particular, covering or moving over any planet.

Transit Instrument. See **Observatory.**

TRANSITION, in music, the softening a disjunct interval by the introduction of intermediate sounds. In harmony, transition is the changing the genus, or mode, in a sensible but regular manner.

Transition Rocks. See **Mineralogy.**

TRANSMUTATION, the act of transforming, or changing one nature, into another. Nature, Sir Isaac Newton observes, seems delighted with transmutations: he goes on to enumerate several kinds of natural transmutations; gross bodies, and light, he suspects, may be mutually transmuted into each other; and adds, that all bodies receive their active force from the particles of light, which enter their composition.

TRANSPARENCY, in physics, a quality in certain bodies whereby they give passage to the rays of light, in contradistinction to opacity, or that quality of bodies which renders them impervious to the rays of light.

TRANSPORTATION, the act of conveying or carrying a thing from one place to another.

Transportation is a kind of punishment, or more properly an alleviation or commutation of punishment, for criminals convicted of felony; who for the first offence, unless it is an extraordinary one, are generally transported to the plantations (at present to New South Wales), there to bear hard labour for a term of years; within which, if they return, they are executed without further trial than identifying their persons.

TRANSPOSITION, in algebra, the bringing any term of an equation over to the other side.

TRANSUBSTANTIATION, in theology, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ, which the Romish church hold is wrought by the consecration of the priest. This is a main point in the Romish religion, and is rejected by the protestants, the former maintaining the transubstantiation to be real, the latter only figurative; interpreting the text, hoc est corpus meum, "this *signifies* my body;" but the council of Trent stood up strenuously for the literal sense of the verb *est*, and say expressly, that in transubstantiation the body and blood of our Lord Jesus Christ are truly, really, and substantially, under the species of bread and wine. The controversies about this point are almost innumerable, a circumstance not to be wondered at when we reflect on the little attention paid by the generality of the Christian world to the language in which Jesus expressed himself, which was purely symbolical.

TRANSVERSE, something that goes across another, from corner to corner; thus bends and bars, in heraldry, are transverse pieces or bearings.

TRAP, in mineralogy, is a Swedish term signifying stair. It was first applied to desig-

nate a certain class of mountains, composed of nearly horizontal strata, with perpendicular breaks, which were supposed to give a rude resemblance to a flight of stairs.

TRAPEZIUM. See GEOMETRY.

TRAVERSE, in law, signifies sometimes to deny, sometimes to overthrow or undo a thing, or to put one to prove some matter; much used in answer to bills in chancery: or it is that which the defendant pleads or says in bar to avoid the plaintiff's bill, either by confessing and avoiding, or by denying and traversing the material part thereof.

TRAVESTY, or TRAVESTI, a French term, derived from the verb travestir, to disguise one's self, or to appear in masquerade: and hence, travesty is applied to the disfiguring of an author, or the translating him into a style and manner different from his own, by which means it becomes difficult to know him.

TREACLE. See SUGAR, &c.

TREAD-*mill*, a mill erected in a prison for the purpose of grinding corn, differing from other mills only in this, that the moving power is supplied by the prisoners who are stationed on the main wheel for this purpose.

TREASON, in law, is divided into high treason and petty treason. High treason is defined to be an offence committed against the security of the king or kingdom, whether it be by imagination, word, or deed; as to compass or imagine the death of the king, queen, or prince, or to deflower the king's wife, or his eldest daughter unmarried; or his eldest son's wife; or levy war against the king in his realm, adhere to his enemies, counterfeit his great seal, privy seal, or money, or wittingly to bring false money into this realm, counterfeited like the money of England, and utter the same; to kill the king's chancellor, treasurer, justices of either bench, justices in eyre, of assize, or of oyer and terminer, being in their place doing this office; forging the king's sign manual or privy signet, privy seal, or foreign coin current here, or diminishing or impairing current money. In case of treason, a man shall be drawn, hanged, and quartered, and forfeit his lands and goods to the king.

TREASON, *petit.* Whenever a wife murders her husband, a servant his master, or mistress, or an ecclesiastic a prelate, or to whom he owes obedience, every one of these offences is petit treason.

As every petit treason implies a murder, it follows, that the mere killing of a husband, master, or prelate, is not always petit treason; for if there are not such circumstances in the case of killing one of these persons, as would have made it murder in the case of killing any other person, it does not amount to this offence.

There can be no accessary in high treason. And it seems to be always agreed that what would have made a man an accessary before the fact in any other felony, makes him a principal in high treason.

TREASURE TROVE, is where any money or coin, gold, silver, plate, or bullion, is hidden in the earth, or other private place, the owner being unknown: in which case, the treasure belongs to the king, or some other who claims by the king's grant or by prescription. But if he that hid it is known, or afterwards found out, the owner, and not the king, is entitled to it. If it is found in the sea, or upon the earth, it does not belong to the king, but to the finder, if no owner appear.

TREASURER, an officer to whom the treasure of a prince, or corporation, is committed to be kept and duly disposed of.

TREMELLA, a genus of plants of the class of cryptogamia, and natural order of algæ. It is of a gelatinous membranous substance; the parts of the fructification scarcely visible. There are eleven species.

TREMOLITE. See MINERALOGY.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach more securely to the place attacked; whence they are also called lines of approach.

TRESPASS, is any transgression of the law, under treason, felony, or misprision of either.

TRET, in commerce, an allowance made for the waste or the dirt, that may be mixed with any commodity, which is always four pounds in every hundred and four pounds weight.

TRIAL, the proceeding of a court of law, when the parties are at issue, such as the examination of witnesses, &c. to enable the court deliberately weighing the evidence given on both sides, to draw a true conclusion, and administer justice accordingly.

TRIANDRIA, in the Linnæan system of botany, a class of plants, the third in order; comprehending all such plants as have hermaphrodite flowers, with three stamina, or male parts, in each; whence the name.

TRIANGLE. See GEOMETRY.

TRIANGULAR COMPASSES, are such as have three legs, or feet, whereby to take off any triangle at once; much used in the construction of maps, globes, &c.

TRICHECUS, the *walrus,* in natural history, a genus of mammalia of the order bruta. Generic character: no fore-teeth in the full grown animal, above or below; tusks in the upper jaw solitary; grinders with wrinkled surfaces; body oblong; lips doubled; hind feet stretched, uniting into a fin. These animals are all natives of the sea, and feed on sea-weeds and shell-fish, but are never known to eat flesh. There are three species, of which the principal are, *Trichecus rosmarus,* the arctic walrus, or the morse. This is an animal of a very inelegant structure. It has a small head to a vast body. Its under lip is covered with bristles nearly of the thickness of a crow-quill. In its upper jaw it has two large tusks from one to two feet in length, and weighing from three to twenty pounds. The walrus sometimes grows to the length of eighteen feet, and the circumference, about the thickest part, of twelve. It is principally found in the high latitudes of the Northern Ocean. These animals are gregarious, and are often seen upon floating masses of ice, in immense numbers, the greater part sleeping, but some always on the watch to give notice of approaching danger. They are harmless when not provoked, but some accounts represent them as highly formidable in a state of irritation, the efforts of many being combined against the enemy, and fastening with their teeth against boats to make holes in them, or draw them to the bottom.

Trichecus borealis, or the whale-tailed manati, inhabits the seas between Kamtschatka and America. These animals live in families, generally consisting of a male and female, and two young ones of different ages, and the at-

tachment of the male to the female is so great, that he will defend her when attacked to the last extremity; and if she happens to be destroyed and dragged to the shore, he will swim for some days off the fatal and detested spot. The manati approaches very nearly to the cete tribe, and its feet are little more than pectoral fins. It attains the immense length of twenty-seven feet, and the weight of four tons. In winter it is extremely lean, and its ribs may be distinctly numbered. It will, when pierced with the harpoon, sometimes adhere to rocks with its feet with uncommon tenacity, and when forced from them by a cord drawn by thirty men or more, is found to have left part of the skin of the feet behind. When any individual is harpooned, others are stated to swim to its aid, endeavouring, some to overturn the boat, others to break the cord, and others again by blows with their tails, striving to dislodge the harpoon. Their sounds somewhat resemble the snorting of a horse. They are never seen on land.

TRICHIURUS, a genus of fishes of the order apodes; the generic character is, head stretched forwards, with lateral gill-covers; teeth ensiform, semisagittate at the tips; gill-membrane seven-rayed; body ensiform, compressed, with subulate finless tail.

TRIFOLIUM, *trefoil* or *clover*, a genus of plants of the class diadelphia, and order decandria, and in the natural system ranging under the 22d order, papilionaceæ. The flowers are generally in round heads; the pod is scarcely longer than the calyx, univalve, not opening, deciduous. The leaves are three together. There are 51 species; of which 17 are natives of Britain.

TRIGONOMETRY. The business of this important science is to find the angles where the sides are given; and the sides of their respective ratios, when the angles are given; and to find sides and angles, when sides and angles are partly given. To effect this, it is necessary not only that the peripheries of circles, but also certain right lines in and about circles, be supposed divided into certain numbers of parts. The ancients, feeling the necessity of such a pre-division, portioned the circles into 360 equal parts, which they called degrees; each degree was again dividid into 60 equal parts, called minutes; and each minute comprised 60 equal parts, called seconds. The moderns have improved upon this division by the addition of a nonius, or vernier, which may be carried to any extent, but is usually limited to decimating the seconds; noting each tenth part thereof.

The following definitions will be found useful: 1. The complement of an arc is the difference thereof from a quadrant: thus, if an arc measures 60 deg. the complement is 30 deg. 2. A chord, or subtense, is a right line drawn from one to the other end of an arc. 3. The sine, or right sine, of an arc, is a perpendicular falling from one end of an arc to the radius drawn, at right angles thereto, towards the other end of the arc. Hence it is clear that an arc of 60 deg. must have its secant, its radius, and its chord, all of the same length, forming an equilateral triangle. The secant and radius both proceed from the centre, but all sines are parallel to a vertical line passing through the centre and invariably fall upon a dian[illegible]r; drawn perpendicular to that right line.

For the same reason that we avoided giving a system of arithmetic in this little work, we may perhaps be expected to pass by the doctrin of trigonometry; but as works on this subject are much more expensive than works on common arithmetic, we shall here subjoin the leading rules for plane trigonometry.

Case I. When two of the three given things are a side and its opposite angle, to find the rest.

Rule. The sides of any plane triangle are to each other as the sines of their opposite angles, and vice versa:—That is,

As any side is to the sine of its opposite angle, so is the sine of any other angle to its opposite side.

Or, As the sine of any angle is to its opposite side, so is the sine of any other angle to its opposite side.

Hence, to find an angle, begin the proportion with a side opposite to a given angle; and to find a side, begin with an angle opposite to a given side.

Example I. In the plane triangle ABC, fig. 5, plate LI.

$$\text{Given}\begin{cases}AC\ 236\\ BC\ 350\\ \angle B\ 38^\circ\ 40'\end{cases}\text{yards. Required the other parts.}$$

By Calculation.

As side AC	-	236		2.3729120
				7.6270880
Is to sine ∠B	-	38° 40′		9.7957330
So is side BC	-	350	-	2.5440680
To Sine ∠A	67° 51′	or	112° 6′	9.9668890
	38° 40′		38° 40′	
Sum	106° 31′	or	150° 46′	
Subtract	180° 0′		180° 0′	
Leaves	73° 26′	or	29° 14′ ∠C	

Then,

: Sine ∠ B 36° 40′	9.7957330
	0.2042670
: Side AC 236 -	2.3729120
: : Sine ∠ C 29° 14′	9.6887467
: Side AB 184.47	2.2659257

Case II. When two sides and their included angle are given, to find the rest.

Rule as the sum of any two sides of a plane triangle, is to their difference, so is the tangent of half the sum of their opposite angles, to the tangent of half their difference.

Then the half difference of these angles, added to their half sum, gives the greater angle, and subtracted from it gives the less.

And as all the angles are now known, the remaining side may be found by Case I.

Note. Instead of the tangent of half the sum of the two unknown angles, we may use the co-tangent of half the given angle, or the tangent of half its supplement, which are all equal to each other.

Example. In any plane triangle ABC,

$$\text{Given}\begin{cases}AB\ 1075\\ BC\ 2394\\ \angle B\ 34^\circ\ 46'\end{cases}\text{feet. Required the rest.}$$

By Calculation.

$AB + BC$ 3469 - 3.54

6.4597957
$AB \backsim BC$ 1319 3.1202448
.: Tan. $\frac{A+C}{2}$ 72° 37′ 10.5043702

Tan. $\frac{A \backsim C}{2}$ 50° 32′ 10.0844107

Sum 123° 9′ $\angle A$
Diff. 22° 5′ $\angle C$.

Then,
: Sine $\angle A$ 123° 9′ or 56° 51′ 9.9228509

0.0771491
: Side BC - 2394 - 3.3791241
:: Sine $\angle B$ - 34° 46′ - 9.7560544

Side AC - 1630.5 - 3.2123276

Case III. When the three sides are given, to find the angles.

Rule. Make the longest side the base, and let fall a perpendicular upon it from the opposite angle.

Then, as the base or sum of its segments, is to the sum of the other two sides, so is the difference of those sides, to the difference of the segments of the base.

And half this difference, being added to half the base, will give the greater segment; and subtracted from it, will give the less.

Then, in each of the right-angled triangles, formed by the perpendiculars, there will be known two sides and an angle opposite to one of them; from whence the other angles may be found, by Case I.

Example I. In any plane triangle ABC, fig. 6.

Given $\begin{cases} AB\ 464 \\ AC\ 348 \\ BC\ 690 \end{cases}$ yards. Required the angles.

By Calculation.

Having let fall the perpendicular AD, it will be
: BC or $BD + DC$ 690 - 2.8388941

7.1611509
: $AB + AC$ 812 - 2.9095560
:: $AB \backsim AC$ 116 - 2.0644580

: $BD \backsim DC$ 136.51 2.1351649

$$\text{Hence } \frac{690 + 136.51}{2} = 413.25 = BD.$$

$$\text{And } \frac{690 - 136.51}{2} = 276.75 = CD.$$

Then, in the triangle ABD, right-angled at D,
: AB - 464 - 2.6665180
: BD - 413.25 - 2.6162129
Sine $\angle D$ - 90° - 10.0000000

Sine $\angle BAD$ 62° 57′ - 9.9496949
90° 0′

27° 3′ $\angle B$.

And, in the triangle ACD, right-angled at D,
: AC - 348 - 2.5415792
: DC - 276.75 - 2.4420876
:: Sine $\angle D$ 90° 0′ - 10.0000000

Sine $\angle CAD$ 52° 40′ 9.900508
90° 0′

37° 20′ $\angle C$
Also 62° 57′ $\angle BAD$
And 52° 40′ $\angle CAD$

Makes 115° 37′ $\angle BAC$.

Whence $\angle B = 27° 3′$, $\angle C = 37°'25$, and $\angle BAC = 115° 37′$.

Case IV. In any right angled triangle, As radius is to the tangent of either of the acute angles, so is the side adjacent to that angle, to the side opposite to it; and vice versa.

Example I. In any right-angled plane triangle ABC, fig. 7.

Given $\begin{cases} BC\ 324 \\ \angle B\ 53° 7′ 48″ \end{cases}$ Required the other parts.

By Calculation.

: Rad. or sine - 90° - 10.0000000
: Tan. $\angle B$ - 53° 7′ 48″ 10.1249371
:: Side BC 324 2.5105450

: Side AC 432 2.6354821

: Sine $\angle A$ or cos. $\angle B$ 53° 7′ 48′ 9.7781524
: Side BC - - 324 - 2.5105450
: Rad. or sine $\angle C$ - 90° - 10.0000000

: Side AB - - 540 - 2.7323926

And 90° 53° 7′ 48″ = 36° 52′ 12″ $\angle A$.

TRILLION, in arithmetic, a billion of billions.

TRIM *of a ship*, her best posture, proportion of ballast, and hanging of her masts, &c. for sailing. To find the trim of a ship is to find the best way of making her sail swiftly, or how she will sail best.

TRINGA, *sandpiper*, a genus of birds belonging to the order of grallæ. The bill is somewhat tapering, and of the length of the head; the nostrils are small; the toes are four in number and divided, the hind toe being frequently raised from the ground. According to Dr. Latham, there are 45 species, of which 18 are British.

TRINITARIANS, those who believe in the trinity: those who do not believe therein, being called anti-trinitarians.

TRINITY-*house*, a kind of college at Deptford, belonging to a company or corporation of seamen, who, by the king's charter, have power to take cognizance of those persons who destroy sea-marks, and to get reparation of such damages; and to take care of other things belonging to navigation. At present, many gentry and some nobility are members of that community.

TRINOMIAL, or Trinomial root, in mathematics, is a root consisting of three parts connected together by the signs + or —, as $x + y + z$, or $a + b - c$.

TRIO, in music, a part of a concert wherein three persons sing; or more properly a musical composition consisting of three parts. Trios are the finest kinds of composition, and these are what please most in concerts.

TRIPLE *time*, in music, a time consisting of three measures in a bar; the two first of which are beat with the hand or foot down and the third marked by its elevation

TRIPOLI, a mineral found sometimes in an earthy form, but more generally indurated. Its texture is earthy. Specific gravity 2 to 2.5. It absorbs water, feels harsh and dry. Scarcely adheres to the tongue; takes no polish from the nail; does not stain the fingers. Colour gene- [illegible] also different kinds of yellow, brown, and white.

TRISECTION, or TRISSECTION, the dividing a thing into three. The term is chiefly used in geometry, for the division of an angle into three equal parts. The trisection of an angle geometrically, is one of those great problems whose solution has been so much sought by mathematicians for these two thousand years, being in this respect on a footing with the quadrature of the circle, and the duplicature of the cube angle.

TRITICUM, *wheat*, a genus of plants of the class triandria, and order digynia, and in the natural system ranging under the fourth order, gramina. The calyx is bivalve, solitary, and generally containing three florets; the corolla is bivalve, one valve being bluntish, the other acute. There are 19 species.

TRITOMA, a genus of insects of the coleoptera order. The generic character is, antennæ clavate, the club perfoliate; lip emarginate; anterior feelers hatched-shaped; shells as long as the body. There are 10 species.

TRITON, a genus of vermes mollusca. The generic character is, body long: mouth with an involute spiral proboscis; tentacula, or arms twelve, viz. six on each side, divided nearly to the base, the end ones cheliferous. There is only a single species.

TROCHAIC VERSE, in the Latin poetry, a kind of verse, so called because the trochees chiefly prevail, as the iambus does in the iambic. It generally consists of seven feet and a syllable; the odd feet, for the most part, consist of trochees, though a tribrachys is sometimes admitted, except in the seventh foot; these two feet are likewise used in the other places, as is also the spondæus, dactylus, and anapæstus. The following is an example:

1 2 3 4 5 6
Solus | aut rex | aut po | eta | non quot | annis |
7 ½
nasci | tur.

TROCHEE, in the Greek and Latin poetry, a foot consisting of two syllables; the first long and the second short, as in the words *mūsă* and *sērvăt*.

TROCHILUS, *humming bird*, a genus of birds belonging to the order of picæ.—The rostrum is subulate, filiform, and longer than the head, the apex being tubular; the upper mandible sheaths the lower. The tongue is filiform and tubulous, the two threads coalescing; the feet are slender and fit for walking; the tail has ten feathers. There are 65 species, none of which are natives of Britain. They are all remarkable for the beauty of their colours, and most of them for the smallness of their size, though some are eight or nine inches in length. They are divided into two families, viz. those with crooked bills, and those with straight bills.

TROGON, or *curucia*, a genus of birds of the order picæ. The generic character is. bill shorter than the head, sharp edged, hooked, the mandibles serrate, at the edge; feet formed for climbing. There are nine species.

TRONAGE, the mayor and commonalty of the city of London, are ordained keepers of the beams and weights for weighing merchants commodities, with power to assign clerks, porters, &c. of the great beam and balance, which weighing of goods and wares is called tronage.

TROPÆOLUM, the *Indian cress*, or *nasturtium*, a genus of the octandria-monogynia class of plants, the flower of which consists of five roundish petals inserted into the divisions of the cup; the two upper petals are sessile; the three others have very long and barbated ungues: the fruit consists of three convex capsules, fulcated, and striated on one side, and angular on the other; the seeds are three, gibbous on one side, and angulated on the other, but upon the whole somewhat roundish, and striated deeply. There are five species.

TROPHY, *tropæum*, among the ancients a pile or heap of arms of a vanquished enemy, raised by the conqueror in the most eminent part of the field of battle. The trophies were usually dedicated to some of the gods, especially Jupiter. The name of the deity to whom they were inscribed, was generally mentioned, as was that also of the conqueror.

TROPICS. See ASTRONOMY, and GEOGRAPHY.

TROVER is the remedy prescribed by the law, where any person is in possession of the property of another, which he unlawfully detains.

TROUT. See SALMO.

TROY-*weight*, one of the most ancient of the different kinds used in Britain. The ounce of this weight was brought from Grand Cairo in Egypt, about the time of the crusades, into Europe, and first adopted in Troyes, a city of Champagne, whence the name. The pound English troy contains 12 ounces, or 5760 grains.

TROY-*weight*, *Scots*, was established by James VI., in the year 1618, who enacted, that only one weight should be used in Scotland, viz. the French troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7600 grains, and is equal to 17 oz. 6 dr. avoirdupois. The cwt. or 112 lb. avoirdupois, contains only 103 lb. 2¼ oz. of this weight, though generally reckoned equal to 104 lb. This weight is nearly, if not exactly, the same as that of Paris and Amsterdam; and is generally known by the name of Dutch weight. Though prohibited by the articles of union, it is still used in weighing iron, hemp, flax, most Dutch and Baltic goods, meal, butchers-meat, unwrought pewter, and lead, and some other articles.

TRUCE, in war, denotes a suspension of arms, or a cessation of hostilities between two armies, in order to settle articles of peace, bury the dead, or the like.

TRUFFLES, in natural history, a kind of subterraneous puff-ball, being a species of fungi, which grows under the surface of the earth. See LYCOPERDON.

TRUMPET, the loudest of all portable wind instruments, and consisting of a folded tube generally made of brass, and sometimes of silver.

TRUMPET, *hearing*, is an instrument to assist the hearing of persons who are deaf. Instruments of this kind are formed of tubes, with a

wide mouth, and terminating in a small canal, which is applied to the ear. The form of these instruments evidently shows how they conduce to assist the hearing; for the greater quantity of the weak and languid pulses of the air being received and collected by the large end of the tube, are reflected to the small end, where they are collected and condensed; thence entering the ear in this condensed state, they strike the tympanum with a greater force than they could naturally have otherwise done.

TRUMPET, *speaking*, is a tube from six to fifteen feet long, made of tin, perfectly straight, and with a very large aperture; the mouth-piece being large enough to receive both lips. It is used for magnifying sound, particularly that of speech, and thus causing it to be heard at a great distance.

TRUNCATED, in general, is an appellation given to such things as have, or seem to have, their points cut off.

TRUNCHEON, a short staff, or battoon, used by kings, generals, and great officers, as a mark of their command.

TRUNNIONS, or **TRUNIONS** *of a piece of ordnance*, are those knobs or bunches of the gun's metal which bear her up on the cheeks of the carriage.

TRUSS, a bundle, or certain quantity of hay, straw, &c. A truss of hay is to contain fifty-six pounds, or half an hundred weight; thirty-six trusses make a load.

TRUSS, is also used for a sort of bandage or ligature, made of steel, or the like matter, wherewith to keep up the parts, in those who have hernias or ruptures.

TRUST, is a right to receive profits of land, and to dispose of the land in equity; and one holding the possession and disposing thereof at his will and pleasure, are signs of trust.

TUBE, in general, pipe, conduit, or canal; a cylinder, hollow within side, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage or conveyance through.

TUBE, in astronomy, is sometimes used for a telescope, or, more properly, for that part into which the lenses are fitted, and by which they are directed and used.

TUBULARIA, a genus of zoophyta: stem tubular, simple or branched, fixed by the base: animal proceeding from the end of the tube, and having its head crested with tentacula. There are 26 species.

TUFAS, beds of lime deposited on vegetables, which by their destruction give great lightness and porousness to the mass.

TULIPA, *tulip*, a genus of plants of the class hexandria, and order monogynia, and in the natural system ranging under the 10th order, coronariæ. The corolla is hexapetalous and campanulated, and there is no stile. The species of this genus are five; the sylvestris, or Italian yellow tulip, a native of the south of Europe; the gesneriana, or common tulip, a native of the Levant: the breyniana, or Cape tulip, a native of the Cape of Good Hope, the biflora, and the suavolens.

TUMOUR, or **TUMOR**, in medicine and surgery, a preternatural rising or hard swelling on any part of the body.

TUN, or **TON**, originally signifies a large vessel or cask of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandize, for convenience of carriage; as brandy, oil, sugar, skins, hats, &c. This word is also used for certain vessels of extraordinary bigness, serving to keep wine for several years.

TUN is also a certain measure for liquids, as wine, oil, &c.

TUN is also a certain weight, whereby the burden of ships, &c. are estimated.

TUNE, or **TONE**, in music, that property of sounds whereby they come under the relation of acute and grave to one another.

TUNGSTEN. See CHEMISTRY.

TUNGSTEN, a mineral found in Sweden, of an opaque white colour and great weight, whence its name tungsten, or ponderous stone. This ore was analysed by Scheele, who found that it was composed of lime and a peculiar earthy-like substance, which from its properties he called tungstic acid.

TUNGSTIC *acid*. The substance called tungstic acid by Scheele and Bergman was discovered by Scheele in 1781. This philosopher obtained it from the tungstat of lime, by treating it with nitric acid and ammonia alternately. The acid dissolves the lime, and the ammonia combines with the tungstic acid. The ammoniacal solution, when saturated with nitric or muriatic acid, deposits a white powder, which is the tungstic acid of Scheele.

TUNICA, a kind of waistcoat or under-garment, in use amongst the Romans.

TURBO, the *wreath*, in zoology, a genus of insects belonging to the order of vermes testacea. The animal is of the snail kind; the shell consists of one spiral solid valve, and the aperture is orbicular. There are 66 species.

TURDUS, the *thrush*, a genus of birds belonging to the order of passeres. The bill is straight, bending towards the point, and slightly notched near the end of the upper mandible. The nostrils are oval, half covered with a membrane; the corners of the mouth are furnished with a few slender hairs, and the tongue is slightly jagged at the end. Gmelin enumerates 135 species, the principal of which are:

Turdus viscivorus, or the missel-thrush. This bird is well known throughout Europe, and some think confined to it. In England it is stationary, in some other countries migratory. It builds its nest of moss and leaves in low trees, or rather shrubs, and lays four eggs. It feeds on the berries of holly, hawthorn, and other trees, and on caterpillars and insects. It is valued for food, but far more for that melody, which ought ever to be its security from the gun of the sportsman, and which it frequently commences so early as the very beginning of the year, animating the dulness, and softening the rigour of the season by its delightful song.

Turdus musicus, or the throstle, is nine inches long, and weighs three ounces, being considerably less than the former. It breeds so early as the beginning of April, and sometimes again in each of the two following months. Its nest is made of earth, straw, and moss, and plastered inside with clay. It is never seen in companies in England, where it remains through the whole year: in France it is migratory. Its song commences early in the season, and continues for

nine months, and its notes are so rich and various, that, in the language of Milton, they can "charm all sadness but despair."

Turdus pilaris, or the field-fare, is ten inches long, passes the winter in England, when the season is extremely rigorous, in immense flocks, but in small parties when the winter is mild. These birds are said to have been much esteemed for the table by the Romans. In Sweden they build in high trees. They subsist principally on various sorts of berries.

Turdus merula, or the black-bird, is ten inches long, and found generally throughout Europe. It is fond of solitude, and never, or very rarely, seen in flocks. In summer it haunts orchards and gardens. In winter it secludes far from human society in the recesses of the woods. It lays four or five eggs of a dusky green colour, marked with irregular spots. The note of the male is extremely fine, but too loud for any place except the woods; it begins to sing early in the spring, continues its music part of the summer, desists in the moulting season, but resumes it for some time in September and the winter months.

TURKEY. See MELEAGRIS.

TURMERIC. See CURCUMA.

TURNING, the art of forming hard bodies, as wood, ivory, or iron, into a round or oval shape, by means of a machine called a lathe, of which there are various kinds, and several instruments, as gouges, chisels, drills, formers, and screw-tales, used for cutting what is to be turned into its proper form as the lathe turns round. The lathe should be fixed in a place very well lighted; it should be immoveable, and neither too high nor too low. The puppets should neither be so low as to oblige the workman to stoop in order to see his work properly, nor so high that the little chips, which he is continually driving off, should come into his eyes.

To succeed in turning iron, it is necessary to have a lathe exceedingly strong in all its parts, and exceedingly well fixed. The puppets should be short, and the rest well fixed very near the work; the back of the rest should be two or three lines lower than the iron to be turned.

For turning ovals, a lathe of somewhat different construction is used. The axis or spindle, having on it the pulley over which the band-cord passes for turning the lathe, is fixed between the two puppets so as to turn round easily; one end of it passes through one of the puppets, and to it is firmly fixed a circular plate of brass, so that it turns round along with the spindle. Upon this plate two brazen segments of circles are fastened, the circumferences of which correspond to the circumference of the plate, their chords are parallel and equally distant from the centre of the plate, so that they leave a distance between them. They have a groove in each of them; in these grooves another plate is placed, which exactly fills up the space between the two grooves, but is shorter than the diameter of the larger circular plate on which it is laid. This plate is made to slide in the grooves. To its centre is annexed a short spindle, on which the piece of wood to be turned is fixed. When the lathe is set a going, the circular plate moves round, and carries the piece along with it; the plate of brass on which the piece is fixed, being fixed loosely in the grooves already described, slides down a little every time that the grooves become perpendicular to the floor (and there are particular contrivances to prevent it from sliding down too far); and by these two motions combined (the circular one of the large plate, and the straight one of the small), the circumference of the piece of wood to be turned necessarily describes an oval; and gouges or other tools being applied in the usual manner, supported on the rest, it is cut into an oval accordingly. The small plate may be made to slide, either more or less, in the grooves; and by this contrivance the transverse diameter of the oval, or rather ellipse, may be made longer or shorter, at pleasure.

The art of turning is so extensively applicable, that it would require a volume to describe its uses, and the methods of practising it. Every round thing which is made by human hands, may be referred to this art, as one of its products. The largest columns, the most ponderous artillery, and the minutest pivots of watch-work, with all wheel-work, rotatory machines, vessels, &c. are worked in this method.

TURNPIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travellers, waggons, coaches, &c. to take toll of them towards repairing or keeping the roads in repair.

TURPENTINE, a resinous juice extracted from several trees. Common turpentine is obtained largely in the pine forests in the south of France, in Switzerland, in the countries on the north of the Pyrenees, in Germany, and in many of the southern States of North America. The greater part of what is consumed in this country is imported from North America The method of obtaining it is by making a series of incisions through the bark of the tree, from which the turpentine exudes, and falls down into holes, or other receptacles at the foot.

TUTENAG. This name is given in India to the metal zinc. It is sometimes applied to denote a white metallic compound, brought from China, called also *Chinese copper*, the art of making which is not known in Europe. It is very tough, strong, malleable, may be easily cast, hammered, and polished; and the better kinds of it, when well manufactured, are very white, and not more disposed to tarnish than silver is. Three ingredients of this compound may be discovered by analysis: namely, copper, zinc, and iron.

TWILIGHT, that light, whether in the morning before sun-rise, or in the evening after sun-set, supposed to begin and end when the least stars that can be seen by the naked eye cease, or begin, to appear. By means of the atmosphere it happens, that though none of the sun's direct rays can come to us after it is set, yet we still enjoy its reflected light for some time, and night approaches by degrees; for after the sun is hidden from our eyes, the upper part of our atmosphere remains for some time exposed to its rays, and from thence the whole is illuminated by reflection.

The beginning and end of twilight has been variously stated, by different observers; but, in our latitude, it may be said to begin and end when the sun is about eighteen degrees below the horizon: hence, when refraction is

allowed for, the atmosphere must be capable of reflecting sensible light at the height of about forty miles.

TYGER. See FELIS.

TYMPAN, among printers, is a double frame, belonging to the press, covered with parchment, on which the blank sheets are laid, in order to receive the impression.

TYMPANUM, or TYMPAN, in mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves, for the more easy turning the axis, in order to raise a weight required.

TYMPANUM *of a machine*, is also used for a hollow wheel, wherein one or more people, or other animals, walk to turn it; such as that of some cranes, calenders, &c.

TYPE, a copy, image, or resemblance of some model. This word is much used among divines, to signify a symbol, sign, or figure of something to come.

TYPE, among letter-founders and printers, the same with letter.

TYPHA, *cat's-tail*, a genus of plants of the class monœcia, and order triandria; and in the natural system ranging under the third order, calamariæ. The amentum of the male flower is cylindrical; the calyx is scarcely distinguishable; there is no corolla. The female has a cylindrical amentum below the male; the calyx is composed of villous hair; there is no corolla, and only one seed fixed on a capillary pappus. Two species.

TYPOGRAPHY. See PRINTING.

U, V.

U, or V, the twentieth letter of our alphabet. In numerals V stands for five; and with a dash added at top, thus $\bar{V}$, it signifies five thousand. In abbreviations, amongst the Romans, V. A. stood for veterani assignati; V. B. viro bono; V. B. A. viri boni arbitratu; V. B. F. vir bonæ fidei; V. C. vir consularis; V. C. C. F. vale, conjux charissime, feliciter; V. D. D. voto dedicatur; V. G. verbi gratia; Vir. Ve. virgo vestalis; VL. videlicet; V. N. quinto nonarum.

VACATION, in law, is the whole time betwixt the end of one term and the beginning of another. This word is also applied to the time from the death of a bishop, or other spiritual person, till the bishopric, or dignity, is supplied with another.

VACCINATION. Inoculation with the vaccine virus, for the purpose of securing against the infection of the small-pox.

VACCINIUM, the *whortle-berry, or bilberry*, a genus of plants of the class octandria, and order monogynia; and arranged in the natural system under the 18th order, bicornes. The calyx is superior; the corolla monopetalous; the filaments inserted into the receptacle; the berry quadrilocular and polyspermous. There are twenty-seven species.

VACUUM, in philosophy, denotes a space empty, or devoid, of all matter or body.

VADE MECUM, or VENI MECUM, a Latin phrase, used in English to express a thing that is very handy and familiar, and which one usually carries about with them; chiefly applied to some favourite book.

VAGINALIS, a genus of birds of the order grallæ; the generic character is, bill strong, thick, conic-convex, compressed, the upper mandible covered above with a moveable horny sheath; nostrils small, placed before the sheath; tongue above round, beneath flattened, pointed at the tip; face naked, papillous; wings with an obtuse excrescence under the flexure; legs strong, four toed, naked a little above the knees; toes rough beneath, claws grooved. There is but a single species.

VAGRANTS, are all persons threatening to run away and leave their wives and children to the parish. All persons unlawfully returning to the parish or place whence they have been legally removed by order of two justices, without bringing a certificate from the parish or place whereto they belong. All persons who have not wherewith to maintain themselves, live idle, and refuse to work for the usual wages given to other labourers in the like work, in the parishes or places where they are. All persons going from door to door, or placing themselves in the streets, highways, or passages, to beg or gather alms in the parishes or places where they dwell. All these shall be deemed idle and disorderly persons, and one justice may commit such offenders (being thereof convicted before him, by his own view, confession, or oath of one witness,) to the house of correction, to hard labour, not exceeding one month. And any person may apprehend and carry before a justice, any such persons going from door to door, or placing themselves in the streets, highways, or passages, to beg alms in the parishes or places where they dwell; and if they shall resist, or escape from the person apprehending them, they shall be punished as rogues and vagabonds.

VALERIANA, a genus of plants of the class triandria and order monogynia, and in the natural system arranged under the 48th order aggregatæ. There is hardly any calyx; the corolla is monopetalous, gibbous at the base, situated above the germen; there is only one seed. Thirty-one species.

VALLISNERIA, in botany, a genus of the diœcia diandria class of plants, with a monopetalous tripartite flower; its fruit is a long, cylindraceous, and unilocular capsule, containing numerous oval seeds. Two species.

VALVE, in hydraulics, pneumatics, &c. is a kind of lid or cover to a tube, vessel, or orifice, contrived to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture, like the clapper of a bellows.

VALVE, in anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours going one way, and prevent their reflux towards the place whence they came.

VAN, in sea-language, denotes the foremost division of any naval armament, or the part that usually leads the way to battle, or advances first in the order of sailing.

VANE, in a ship, &c. a thin slip of some

kind of matter, placed on high in the open air, turning easily round on an axis or spindle, and veered about by the wind, to shew its direction or course.

VANES, in mathematical or philosophical instruments, are sights made to slide and move upon cross-staves, fore-staves, quadrants, &c

VAPOUR, in meteorology, a thin humid matter, which, being rarefied to a certain degree by the action of heat, ascends to a particular height in the atmosphere, where it is suspended, until it returns in the form of dew, rain, snow, &c.

VARIABLE, in geometry and analytics, is a term applied by mathematicians to such quantities as are considered in a variable or changeable state, either increasing or decreasing. Variable quantities are generally denoted by the last letters of the alphabet, z, y, x, &c.; while the constant ones are denoted by the leading letters, a, b, c, &c.

VARIANCE, in law, signifies any alteration of a thing formerly laid in a plea; or where the declaration in a cause differs from the writ, or from the deed upon which it is grounded.

VARIATION, in geography and navigation, is the deviation of the magnetical needle, in the mariner's compass, from the true north point, towards either the east or west; or it is an arch of the horizon, intercepted between the meridian of the place of observation and the magnetic meridian. See MAGNETISM and NAVIGATION.

VARNISH, a thick, viscid, shining liquor, used by painters, gilders, and various other artificers, to give a gloss and lustre to their works; as also to defend them from the weather, dust, &c.

A coat of varnish ought to possess the following properties: 1. It must exclude the action of the air, because wood and metals are varnished to defend them from decay and rust. 2. It must resist water; for otherwise the effect of the varnish could not be permanent. 3. It ought not to alter such colours as are intended to be preserved by this means. It is necessary, therefore, that a varnish should be easily extended or spread over the surface, without leaving pores or cavities, that it should not crack or scale, and that it should resist water.

Resins are the only bodies that possess these properties, consequently they must form the basis of every varnish. For this purpose, they must be dissolved, as minutely divided as possible, and combined in such a manner, that the imperfections of those that might be disposed to scale, may be corrected by others.

Lac-varnishes or lacquers consist of different resins in a state of solution, of which the most common are mastich, sandarach, lac, benzoin, copal, amber, and asphaltum. The menstrua are either expressed or essential oils, as also alcohol. For a lac-varnish of the first kind, the common painter's varnish is to be united by gently boiling it with some more mastich or colophony, and then diluted again with a little more oil of turpentine. The latter addition promotes both the glossy appearance and drying of the varnish.

A varnish, of the consistence of thin turpentine is obtained for aerostatic machines, by the digestion of one part of elastic gum, or caoutchouc, cut into small pieces, in thirty-two parts of rectified oil of turpentine. Previously to its being used, however, it must be passed through a linen cloth, in order that the undissolved parts may be left behind.

VARNISH, among medallists, signifies the colours antique medals have acquired in the earth.

VAULT, in architecture, an arched roof, so contrived that the stones which form it sustain each other. Vaults are, on many occasions, to be preferred to soffits or ceilings, as they give a greater height and elevation, and are besides more firm and durable.

VECTOR, in astronomy, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipsis, to that centre or focus.

VEER, a sea-term variously used. Thus veering out a rope, denotes the letting it go by hand, or letting it run of itself. It is not used for letting out any running-rope, except the sheet.

VEGETABLE. A vegetable is composed of a root, stem, leaves, flowers, fruits, and seeds; and when all these different parts are fully developed, the vegetable is said to be perfect. When any are deficient, or at least less obvious, the vegetable is said to be imperfect.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chirl, croil, browhen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue. The nap, or shag, called also the velveting, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channelled ruler or needle, which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp.

VENEERING, or VANEERING, a kind of inlaying, whereby several thin slices or leaves of fine woods, of different kinds, are applied and fastened on a ground of some common wood. There are two kinds of inlaying: the one, which is the most common and more ordinary, goes no farther than the making of compartments of different woods; the other requires much more art, in representing flowers, birds, and the like figures. The first kind is properly called veneering; the latter is more properly called marquetry. The wood used in veneering is first sawed out into slices or leaves about a line in thickness; *i. e.* the twelfth part of an inch. In order to saw them, the blocks, or planks, are placed upright, in a kind of sawing press. These slices are afterwards cut into narrow slips, and fashioned divers ways, according to the design proposed; then the joints having been exactly and nicely adjusted, and the pieces brought down to their proper thickness, with several planes for the purpose, they are glued down on a ground or block, with good strong glue. The pieces being thus jointed and glued, the work, if small, is put in a press; if large, it is laid on a bench covered with a board, and pressed down with poles or pieces of wood one end of which reaches to the ceiling of th

room, and the other bears on the board. When the glue is thoroughly dry, it is taken out of the press and finished; first with little planes, then with divers scrapers, some of which resemble rasps, which take off the dents, &c. left by the planes. After it has been sufficiently scraped, they polish it with the skin of a sea-dog, wax, and a brush, or polisher of shave-grass; which is the last operation.

VENTRILOQUISM, an art by which certain persons can so modify their voice, as to make it appear to the audience to proceed from any distance, and in any direction. Some faint traces of this art are to be found in the writings of the ancients; and it is the opinion of M. De la Chapelle, who in the year 1772 published an ingenious work on the subject, that the responses of many of the oracles were delivered by persons thus qualified, to serve the purposes of delusion. As the ancient ventriloquists, when exercising their art, seemed generally to speak from their own bellies, the name by which they were designed was abundantly significant: but it is with no great propriety that modern performers are called ventriloquists, and their art ventriloquism, since they appear more frequently to speak from the pockets of their neighbours, or from the roof or distant corners of the room, than from their own mouths or their own bellies.

The history of ventriloquism affords some very striking instances of the power which it exercises over the imagination. About the beginning of the last century, the famous Tom King, who is said to have been the first man who gave public lectures on experimental philosophy in this country, was attended by the whole fashionable world, for a succession of many nights, to hear him "kill a calf." This performance was done in a separated part of the place of exhibition, into which the exhibitor retired alone; and the imagination of his polite hearers was taxed to supply the calf and three butchers, besides a dog who sometimes raised his voice, and was checked for his unnecessary exertions. It appears, from traditional narrative, that the calf was heard to be dragged in, not without some efforts and conversation on the part of the butchers, and noisy resistance from the calf; that they conversed on the qualities of the animal, and the profits to be expected from the veal; and that, as they proceeded, all the noises of knife and steel, of suspending the creature, and of the last fatal catastrophe, were heard in rapid succession, to the never-failing satisfaction of the attendants; who, upon the rise of the curtains, saw that all these imaginary personages had vanished, and Tom King alone remained to share the praise.

VENUE, in law, the neighbourhood whence juries are to be summoned for trial of causes.

VENUS, in astronomy, one of the inferior planets, revolving round the sun in an orbit between that of Mercury and the Earth.

VENUS, in zoology, a genus of insects belonging to the order of vermes testacea. This animal is a tethys; the shell is bivalve; the hinge with three teeth near each other, one placed longitudinally and bent inwards.

VEPRECULÆ, diminutive from vepres, "a briar or bramble," the name of the 31st order in Linnæus's Fragments of a Natural Method.

VERB, in grammar, a word serving to express what we affirm of any subject, or attribute to it.

VERDEGRIS, is an acetat of copper, useful in the arts as a pigment.

VERDEROR, a judicial officer of the king's forests, chosen by the king's writ in the full county court of the same shire, within the forest where he dwells; he is sworn to maintain and keep the assizes of the forest, and to view, receive, and enrol the attachments and presentments, of all manner of trespasses of vert and venison in the forest.

VERDICT, the answer of a jury made upon any cause, civil or criminal, committed by the court to their examination: and this is twofold, general or special. A general verdict is that which is given or brought into the court in like general terms to the general issue; as guilty or not guilty generally. A special verdict is, when they say at large that such a thing they find to be done by the defendant, or tenant, so declaring the course of the fact, as in their opinion it is proved; and as to the law upon the fact, they pray the judgment of the court: and this special verdict, if it contain any ample declaration of the cause from the beginning to the end, is also called a verdict at large.

VERDITER is a blue pigment, obtained by adding chalk or whiting to the solution of copper in aquafortis.

VERGE signifies the compass of the king's court, which bounds the jurisdiction of the lord steward of the household, and which is thought to have been twelve miles round.

The term verge is also used for a stick or rod, whereby one is admitted tenant to a copyhold estate, by holding it in his hand and swearing fealty to the lord of the manor.

VERGERS, certain officers of the courts of king's-bench and common-pleas, whose business it is to carry white wands before the judges. There are also vergers of cathedrals, who carry a rod tipped with silver before the bishop, dean, &c.

VERJUICE, a kind of harsh, austere vinegar, made of the expressed juice of the wild apple, or crab. The French give this name to unripe grapes, and to the sour liquor obtained from them.

VERMES, in natural history, the last class of the animal kingdom, according to the Linnæan system. The animals in this class are not merely those commonly known by the name of worms, but likewise those which have the general character of being "slow in motion, of a soft substance, extremely tenacious of life, capable of reproducing such parts of their body as may have been taken away or destroyed, and inhabiting moist places." There are five orders in this class, viz. the

Infusoria
Intestina
Mollusca.
Testacea
Zoophyta

VERMICELLI, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces, like worms, by forcing it with a piston through a number of little holes.

VERNIER SCALE, a scale excellently adapted for the graduation of mathematical instruments, thus called from its inventor Peter Vernier, a person of distinction in the Franche Compté. Vernier's method is derived from the following principle:—If two equal right lines,

or circular arcs, A, B, are so divided, that the number of equal divisions in B is one less than the number of equal divisions of A, then will the excess of one division of B above one division of A, be compounded of the ratios of one of A to A, and of one of B to B.

VERSE. See POETRY.

arch.

VERTICAL *circle*, in astronomy, a great circle of the sphere passing through the zenith and nadir, and cutting the horizon at right angles: it is otherwise called azimuth.

VESPA, *wasp*, a genus of insects of the order hymenoptera. The generic character is, mouth with jaws, without proboscis; upper wings pleated; sting concealed; eyes lunated; body smooth.

The genus vespa is of great extent, 140 species; and is remarkable, like that of apis or bee, for the singular dexterity with which it constructs its habitation, which in many species is of considerable size. The common wasp, or vespa vulgaris, is known to every one. The nest of this species is a highly curious structure, and is prepared beneath the surface of some dry bank, or other convenient situation. Its shape is that of an upright oval, often measuring ten or twelve inches at least in diameter: it consists of several horizontal stages or stories of hexagonal cells, the interstices of each story being connected at intervals by upright pillars; and the exterior surface of the nest consists of a great many layers or pieces, disposed over each other in such a manner as best to secure the interior cavity from the effects of cold and moisture; the whole nest, comprising both walls and cells, is composed of a substance very much resembling the coarser kinds of whitish-brown paper, and consists of the fibres of various dry vegetable substances, agglutinated by a tenacious fluid discharged from the mouths of the insects during their operations. The female wasps deposit their eggs in the cells, one in each cell appropriated for that purpose; from these are hatched the larvæ or maggots, which bear a near resemblance to those of bees; they are fed by the labouring wasps with a coarse kind of honey, and when arrived at their full size, close up their respective cells with a fine tissue of silken filaments, and, after a certain period, emerge in their complete or perfect form. The male insect, like the male bee, is destitute of a sting. The society or swarm of the common wasp, consists of a vast number of neutral or labouring insects, a much smaller number of males, and still fewer females. They do not, like bees, prepare and lay up a store of honey for winter use; but the few which survive the season of their birth, remain torpid during the colder months. Wasps in general are both carnivorous and frugivorous.

VESPERTILIO, *bat*, a genus of mammalia, of the order primates. The generic character is, teeth erect, sharp-pointed, approximated; hands palmated, with a membrane surrounding the body, and giving the animal the power of flight. Bats fly only by night, in quest of their food, consisting of gnats and moths, and when deprived of their eyes, appear to feel no want of them, having a supplemental power of perception, by which they avoid objects in the way with nearly as much precision as in their perfect state. In cold climates they pass the winter in torpor, assembling in holes and in caverns, in which they are occasionally seen adhering in great numbers to the walls, and sometimes suspended by their hind legs. The bones of the

enabled to unfold optionally, for flight, or to withdraw into a very small compass, when they wish to repose. The general division is into those which have tails, and those which have none. There are twenty-five species. The common bat is well known, the most remarkable of the species is the vespertilio vampyrus, or vampyre bat.

This remarkable animal is an inhabitant of India and South America, is about twelve inches long, and the extent of its wings is four feet, and in some extraordinary instances, it is said, six. Its tongue is pointed, and terminated by sharp prickles. It is reported to suck the blood of cattle, by inserting the point of its tongue into one of their veins during sleep, so as to excite little or no pain. This is said to be done by them with respect to men also. Various writers, of general respectability, concur in these statements, and have observed, that in some parts of South America, and in India, it is on this account highly dangerous to sleep in the open air, or in apartments with open windows. This property of sucking the blood of human beings has long been affirmed of the bats of Europe; but though assertions of this nature are incapable of being contradicted, there does not appear to be any detail of well authenticated facts in their support. The two last species have no tail.

VESTIBULE, in architecture, a kind of entrance into a large building; being a place before the hall, or at the bottom of the staircase

VESTRY, a place adjoining to a church where the vestments of the minister are kept; also a meeting at such place where the minister, churchwarden, and principal men of most parishes, at this day make a parish vestry.

VESUVIAN, a mineral found in lava, especially at Vesuvius, and formerly confounded with hyacinth. Its colour is brown or greenish. It is found in masses, but usually crystalized in rectangular eight-sided prisms The primitive form of its crystal is the cube. The specific gravity is from 3. 39. to 3. 4.

VETERINARY ART; or FARRIERY, according to the modern acceptation of the term, comprehends the medical treatment of the horse. The first object that comes under notice is the mechanical operation of shoeing.

Shoeing of horses.—The shoes should be made three times as thick at the toe as at the heels, so that by this means the frog may come down to the ground. The nails are all placed forward, four on each side, but not approaching too near the heels. They should be counter sunk in conical or wedge-shaped holes. For horses which go in shafts, or are used in hunting, it is usual to make shoes with only one heel, which should be outward. The horse's heel must be rather lowered on that side, and the inner heel of the shoe somewhat thickened so as to balance and bear equally. The best breadth

for the shoe of a medium-sized horse is said to be one inch at the toe, and three quarters at the heel; the weight about eighteen or twenty ounces. In order to fit the shoe without causing the horse to stand too much on his heels, the under part of the crust, or wall of the hoof, is pared away to receive the excess of thickness in front; for the bottom of the shoe ought to be perfectly flat, without any stubs or calkings in front. Paring away the heels is a most destructive practice, except in case of absolute excrescence in those parts; nor should the bars, (or diagonal ridges) that extend from the heels to the frog, or central projection, ever be cut more than is absolutely proper for the purpose of keeping them in a clean and healthy state. A good open heel is the indication of a powerful foot; hence the sides of shoes ought not to be much contracted. When the heels are tender, what is called a bar-shoe ought to be applied. On the frog the horse chiefly depends for a spring, or resistance, at the bottom of his foot. If this part does not touch the ground, the whole motion will be derived from the upper parts of the limbs and a very uneasy gait will inevitably follow. This points out the necessity for leaving it fully at liberty to come in contact with the ground.

Teeth and age of horses.—The horse has 24 grinders, four tushes or single teeth, and twelve front teeth or gatherers. Mares in general have no tushes. The black mark or cavities denoting the age are to be found in the corner front teeth, adjoining the tushes. At four years and a half old, the mark teeth are just visible above the gum, and the cavity is very conspicuous. At five, the remaining colt's-teeth are shed, and the tushes appear. At six, the tushes are up, and appear white, small, and sharp; near which is observable a small circle of young growing flesh. The horse's mouth is then complete, the corner teeth being filled up. At eight the black marks disappear.

DISEASES.

Horses are subject to various diseases. *Anarsarca*, or dropsy of the skin, generally called the *water farcy*, is known by pits remaining after the skin has been pressed by the finger. The cure is effected by stimulant applications and by diuretics; smart friction and gentle exercise and nourishing food are highly serviceable. When only the lower extremities are diseased, rollers dipt in spirits or in oil of turpentine, will generally remove the complaint.

In *Ascites*, or dropsy of the belly, every means should be used for strengthening and accelerating the secretion in general. Drastic purges, diuretics, sweating, and, in some cases, mercury, seldom fail to render important service.

Bleeding should be performed with a lancet of a suitable size; the fleam being very uncertain and dangerous. The jugular vein is usually opened. A piece of thin cord should be passed round the horse's neck a little above the withers, and the part be wetted, so as to shew the vein. The quantity must depend on the case; but one or two quarts for periodical bleeding are enough to be drawn from a full-sized horse in good condition. When the bleeding is to be stopped, slacken the line, and pass a pin through the lips of the orifice; then with a few hairs, or a piece of thread, pass over the head and point of the pin, in an alternate (i. e. a figure of 8) direction, and make fast.

Breaking-down, proceeds from a rupture of the suspensory ligaments. The fetlock nearly touches the ground, but the foot can be bent when raised. Few cures are made, though much palliation may be effected by reducing the inflammation.

Broken wind, is supposed to proceed from a rupture of the cells in the lungs. The following are among the most frequent causes, viz. catarrhs, working after a full meal, or after drinking freely; girting too tight; being suddenly put into hot stables after standing out in a cold air, &c. &c. The food should be compact and nutritious, such as corn and old hay. Carrots are excellent in this case, as are parsnips and beet roots. The exercise ought to be regular; but never beyond a walking pace.

Canker, is a sharp humour, called the thrush, which in some instances, attacks the sole of the foot, rising like a fungous excrescence, covering the diseased part. Cut away freely from the horny sole, and dress the surface with tow dipped in a solution of lunar caustic.

Catarrh, often called *morfoundering*, is usually the effect of cold. If acute fever attends it, the greatest service will be rendered by warm diluting drinks, or by mild purges, aided by bleeding. The stable ought not to be kept too hot, as it would render the horse tender in his lungs. Encourage the running at the nose.

Corns, consist of extravasated blood or lymph, collected between the crust or wall of the hoof and the bars. Cut away as far as the extravasation, and apply a pledget of lint, dipped in tincture of myrrh, or in balsam of Peru: then turn the horse out to grass without shoes, or let a chambered shoe be put on, so as to avoid pressing the part.

Cough. The following has proved serviceable in chronic cough: Tar eight pounds, lime twelve pounds, water six gallons, mixed. Give a quart every morning.

Cracks in the heels proceed from a gross habit, filth, or washing the legs without rubbing them dry. Wash with strong soap suds, lower the food, give mild purges, or diuretics, and if the habit be full, bleed freely.

Diabetes, or a profuse discharge of urine, is generally incurable. It is often brought on by violent diuretics. Bad food is also a frequent cause. Opium, bark, and other tonics, will give relief.

Diarrhœa is sometimes critical; in which instance it should not be checked, but treated, with copious diluents: when induced by hard labour, with bad stabling, or bad food, it is to be treated with great caution; lest it should degenerate into dysentery inject the anodyne clyster, and give twice daily, opium two drachms, ipecacuanha three drachms, prepared chalk four ounces, thin starch a pint. If it does not answer the intention within four days, give alum whey, and encourage sweat by means of good clothing. Litter well, and allow a moderate current of air if the stable be hot.

Dysentery, commonly called *moltengrease*, is a most dangerous complaint. The animal is usually afflicted with tenesmus, and voids a great quantity of slimy mucus. The safest

purge, in the first stage, is about a quart of castor oil. If that does not remove the fæces, give calomel four drachms, gum arabic two drachms, with honey enough to form a bolus. ample clysters of gruel, linseed, water, &c. should be frequently injected. In obstinate cases administer the following: take ten poppy-heads, boil them in six quarts of water till only a gallon be left, and starch enough to soften into a thin mucilage, throw up three or four times daily. Internally the following may answer: Opium two drachms, ipecacuanha four drachms, nux vomica, in powder, one drachm, port wine one quart. Mix and repeat morning and evening. Let the horse be well clothed, so as to keep his skin moist; the stable should not be hot. If the dung smells offensively the stable must be fumigated and kept extremely clean.

Farcy is easily removed when it consists of merely a superficial inflammation, by burning the bud or swelling with a hot iron, or by caustic; but when the blood is infected, (which is known by the buds being ulcerated and a discharge at the nose,) a scruple of corrosive sublimate, levigated, mixed with butter, or in gruel, must be given in two doses, i. e. night and morning. If the sublimate should prove too powerful, substitute a drachm of calomel, night and morning. Green food is peculiarly serviceable. Destroy the clothing after a cure, or the disease will be regenerated.

Fever. If the common inflammatory symptoms are indicated by the pulse, the eyes, and the general action of the horse, bleeding, emetics, and glyster, are necessary. Avoid whatever is heating; let the animal be kept in a cold stable, and clothed moderately. Let him have plenty of warm drink of a diluent kind. When a fever is symptomatic, the cause must first be removed; in the meanwhile soothing palliating treatment should be resorted to. When the fever is of a malignant species, and the horse is in a robust state, bleed copiously: but if emaciated, or of a weak frame, avoid that evacuation. Wash the body with warm vinegar, in which aromatic herbs have been boiled: remove the dung instantly, and change the bedding twice or thrice within the day. Burn nitre every half hour, so as to occasion a thick smoke, and let a piece of touchpaper be always smothering in a corner of the stable, which ought to be very cool. Keep the body open with antiseptic purges, and use little clothing. Encourage every sore which may appear, and open rowels. This complaint being highly infectious, no other horses or horned cattle, should be allowed to stand within the same area.

Fistulous withers, are very troublesome complaints. Great cleanliness is necessary; and the part should be laid open, if the situation may admit: or, at all events, that a seton should be passed through the bottom of the sore, whence the matter might be discharged. Keep the body open, and let the diet be soft and cooling; allow free ventilation, and approach the animal gently.

Founder, is an affection of the feet. When all the feet are affected the horse lies down, and is unwilling, and perhaps unable to rise. The complaint requires very copious bleeding, and ease and rest. The shoes ought to be taken off, and very soft litter be allowed. Bleeding at the toes rarely fails of giving great relief endeavour to prevent the collection of matter. Purge well, and keep the feet cool by the frequent application of salt and water, or sugar of lead in water, or sal-ammoniac and vinegar. Pare away the crust, so as to liberate the foot from its usual constriction. When recovering, turn the animal out into a rich soft paddock, if the season permits; or into a soft straw yard. Allow no corn, unless when the horse is extremely weak; and then scalded malt, &c will answer best.

Grease. If it proceed from redundancy, bleed, purge, and use gentle exercise, with moderate friction. When from weakness, or over-labour allow rest and nourishing food, giving good standing, and preserving perfect cleanliness.

Gripes, have remissions of pain, which distinguish them from inflammation in the bowels, as does the disposition to roll on the back. Rake well, throw up clysters as warm as can be borne, and in large quantities. If the pain be very acute and obstinate, bleed copiously, and give a lump of opium, about the size of a large hazel-nut. But this must be done before any symptoms of inflammation appear. Foment the bowels with hot water by means of blankets. Give a draught of castor-oil, one pint; oil of peppermint, one drachm; mix them with the yolks of two eggs, and add a pint of water. If the bowels have not been well opened, give calomel, half an ounce; gumgamboge, one drachm; Castile soap, half an ounce; made into bolus, with honey, and given at night; keeping on warm clothing, and cautiously avoiding a draught of wind.

Hepatitis, may be known by a yellowness of the eyes and mouth, attended with considerable fever. Bleed freely, and blister the sides, applying numerous rowels underneath. Rake and clyster; then purge well, by giving the following bolus night and morning, till it operates freely. Calomel, half a drachm; aloes, one drachm and a half; Castile soap, two drachms; mix with honey.

Inflammation, in whatever part is generally the index to blood-letting. But local inflammations which seem to be critical, and push forward to suppuration, should rather be encouraged than resolved; unless they settle upon some part endangering the life. When the *brain* is inflamed, the lancet must be freely used, as must the blistering ointment and purges. The *eye* must, when in a state of irritation be kept cool, and the habit lowered. Mild solutions of white vitriol, added to a few drops of extract of saturn, should be applied, in the form of poultice, cold and frequently. When the stomach is inflamed, bleed, and clyster with soft cooling liquors. In inflamed bladder avoid diuretics; administer clysters, and give mucilaginous, soothing drinks. When the kidneys are inflamed, the animal ought to be kept very low, after ample evacuations, both by bleeding and gentle purges.

Lampas, is a swelling of the bars in the roof of the mouth, chiefly in young horses. Rub the part with alum and honey; if they do not subside, you may scarify the part very slightly with a sharp instrument guarded with tow, &c. near its point, so that you cannot, in case of accident, do injury by making too deep a wound.

Lethargy, is occasioned by too great a determination of blood towards the head. Bleed freely, unless when the debility is great; open the body by active purges, rake, and clyster, and endeavour to excite perspiration. Give nitre three drachms; resin, three drachms; cream of tartar, three drachms; all finely powdered, and mixed with honey into a bolus: repeat every morning, until the discharge of urine is abundant.

Mange, commonly arises from filth, or from poorness of condition, and is extremely infectious. Wash well with soap-suds, and apply common brimstone, levigated, eight ounces; of alum and white vitriol, each five drachms; horse turpentine, three ounces; lard, half a pound; mix and rub frequently.

Pole evil, arises chiefly from the friction of the collar at the back of the ears, or other such cause: it often forms a tumour, which must be brought forward, unless by blistering, &c. the fluid can be removed. Take care to open below the abscess, else there will be danger of sinuses.

Stag-evil, or locked jaw, is often caused by sudden changes from heat to cold. The cure will chiefly depend on opium, the warm bath, and other antispasmodics. Sometimes the sudden application of cold water in great quantities has been serviceable.

Staggers, or *phrensy*, is a variety of lethargy; only that the pressure on the brain is extreme, and the animal rendered outrageous. To effect a cure, bleed copiously, from three to four quarts every eight hours, until the symptoms abate. Blister the head and neck with Spanish flies mixed in spirits of turpentine: rake well, and administer a strong clyster. Let the stables be very cool, and sprinkled with hot vinegar. Give a bolus composed of calomel two drachms; aloes six drachms, Castile soap two drachms, mixed with honey. Allow very little drink. In desperate cases sling the horse, and throw cold water over his head and neck.

Strangles. This disease usually begins with a fever, a cough, a running at the nose, and a swelling at the sub-maxillary glands. Repel, if possible, by copious bleedings, opening the body, exciting perspiration, and by gentle diuretics. Give, night and morning, nitre six drachms, cream of tartar six drachms, emetic tartar a drachm and a half, warm gruel one quart.

Swelled legs. Gentle exercise and friction will be found the safest and most effectual remedy.

Thrush or *running-thrush*, is a discharge from the sensible frog. The running ought to be dried, taking care to bring the frog into action, by lowering the heels gradually, and bearing upon it by means of a bunch of tow. Use as warm as it can be borne, a wash composed of tar two ounces, and six drachms of oil of vitriol. Gentle purges and mild diuretics will greatly aid towards a cure.

Ulcers require soft dressings, and their edges should be kept low, and free from callous matter. Dress often, and in case of a sinus be careful to have the vent downwards, so that the discharge may be free. If fungous flesh arise, or the edges become hard, touch with blue vitriol, or with lunar caustic, and alteratives must be given. When the wound cicatrizes, apply a little lard very gently to soften the skin; and if the flies are troublesome, mix a very small quantity of tobacco in the lard.

Warbles, from under the saddle, in consequence of unequal pressure. Perfect rest is the best remedy; but a solution of sugar of lead in vinegar will greatly promote dispersion. If they become firm, blister them, or fully extirpate by the knife.

Wind-galls must be removed by firm pressure on a bolster that immediately sits upon the swelling; when subdued, the part should be fired, to prevent recurrence of the complaint. The sweating blister, made by steeping Spanish flies in vinegar, often has a good effect.

Worms. When a horse rubs his tail, and a yellow matter appears at times about the anus, worms may be suspected. Common salt is one of the most powerful remedies; but subjects the horse to considerable inquietude. The root of the male fern, levigated, and given fresh, is highly extolled, as is soot also. Strong doses of calomel and gamboge will be found the most efficient, provided they be persevered in so as to scour for a number of days; but this must greatly depend on the condition and constitution of the horse.

VIBRATION, in mechanics, a regular reciprocal motion of a body, as a pendulum, &c. which, being freely suspended, swings or oscillates, first this way, then that.

VICAR, one who supplies the place of another. The priest of every parish is called rector, unless the prædial tithes are appropriated, and then he is styled vicar; and when rectories are appropriated, vicars are to supply the rector's place.

VICARAGE. For the most part vicarages were endowed upon appropriations; but sometimes vicarages have been endowed without any appropriation of the parsonage; and there are several churches where the tithes are wholly impropriated, and no vicarage endowed; and there the impropriators are bound to maintain curates to perform divine service, &c.

VICE, in smithery, and other arts employed in metal, is a machine or instrument, serving to hold fast any thing they are at work upon, whether it is to be filed, bent, rivetted, &c.

Vice, *hand*, is a small kind of vice serving to hold the lesser works, that require often turning about.

Vice, is also a machine used by the glaziers to turn or draw lead into flat rods, with grooves on each side to receive the edges of the glass.

VICINAGE. Common of vicinage is, where the inhabitants of two townships, which lie contiguous, have usually inter-commoned with one another, the beasts of the one straying mutually into the other's fields without any molestation from either.

VILLAIN, or *Villein*, in our ancient customs, denotes a man of servile and base condition, viz. a bondman or servant; and there were anciently two sorts of bondmen or villains in England: the one termed a villain in gross, who was immediately bound to the person of his lord and his heirs; the other a villain regardant to a manor, he being bound to his lord as a member belonging and annexed to the manor whereof the lord was owner.

VINE. See Vitis.

VINEGAR is a liquid of a reddish or yellowish colour, a pleasant sour taste, and an agreeable odour. Its specific gravity varies from 1.0135 to 1.0251, and it differs also in its other properties according to the liquid from which it has been procured. It is very subject to decomposition: but Scheele discovered that if it is made to boil for a few moments, it may be kept afterwards for a long time without alteration. Besides acetic acid and water, vinegar contains several other ingredients, such as mucilage, tartar, a colouring matter, and often also two or more vegetable acids. When distilled at a temperature not exceeding that of boiling water, till about two thirds of it have passed over, all these impurities are left behind, and the product is pure acid diluted with water.

VINEYARD, a plantation of vines.

VIOL, a stringed instrument resembling in shape and tone the violin, of which it was the origin; that impressive and commanding instrument being little more than an improvement of the old viol.

VIOLA, a tenor violin. This instrument is similar in its tone and formation to the violin, but its dimensions are somewhat greater, and its compass a fifth lower in the great scale of sounds.

Viola, a genus of plants of the class syngenesia, order monogynia; in the natural system arranged under the 29th order, campanaceæ. The calyx is pentaphyllous; the corolla five-petalled, irregular with a nectarium behind, horn-shaped: the capsule is above the germen, three-valved, monolocular, 43 species.

VIOLIN, or *Fiddle*, a well known stringed instrument of brilliant tone and active execution. The four strings of which it consists, are tuned in fifths from each other. The pitch of the lowest string is G, under the second ledger line in the treble stave; consequently that of the next is D, under the first line of the stave; the pitch of the next above that A on the second space; and that of the upper string, E on the fourth space.

VIOLONCELLO, a bass viol, containing four strings, the lowest of which is turned to double C. The strings are in fifths, consequently the pitch of that next the gravest is C gamut; that of the next, D on the third line in the bass; and that of the upper string, A on the fifth line.

VIPER. See Serpentes.

VIRGO, in astronomy, one of the signs or constellations of the zodiac, and the sixth according to order.

VITIS, a genus of the class pentandria, and order monogynia; and in the natural system arranged under the 46th order, pectoraceæ. The petals cohere at the top, and are withered; the fruit is a berry with five seeds. There are 12 species; the most important of which is the vinifera, or common vine, which has naked, lobed, sinuated leaves. There are a great many varieties; but a recital of their names would be tiresome without being useful. All the sorts are propagated either from layers or cuttings; the former of which methods is greatly practised in England, but the latter is much preferable.

VITRIOL, *martial* or *sulphat of iron*. In commerce it is usually denominated green vitriol or copperas. It is not prepared by dissolving iron in sulphuric acid, but by moistening the pyrites which are found native in abundance, and exposing them to the open air. They are slowly covered with a crust of sulphat of iron, which is dissolved in water, and afterwards obtained in crystals by evaporation. Sometimes the salt is found ready-formed, either in a state of solution in water, or mixed with decayed pyrites. In some cases it is found necessary to roast the pyrites before they can be made to undergo spontaneous decomposition. Sulphat of iron has a fine green colour. Its crystals are transparent rhomboidal prisms, the faces of which are rhombs with angles of 79 deg. 50 min. and 100 deg. 10 min. inclined to each other at angles of 98 deg. 37 min. and 81 deg. 23 min. It has a very strong styptic taste, and always reddens vegetable blues. Its specific gravity is 1.8399. It is soluble in about two parts of cold water, and in $\frac{3}{4}$ths of its weight of boiling water. It is insoluble in alcohol.

VITUS'S DANCE. See Medicine.

VIVERRA, a genus of quadrupeds of the order of feræ. The generic character is, cutting-teeth six, sharpish; canine teeth longer; tongue in some smooth, in others aculeated backward; body of a lengthened form. This genus comprehends all the animals of the weasel kind, which seem to be somewhat unnecessarily separated by Linnæus into two distinct genera, under the titles viverra and mustela; in which latter genus the otters are also included. There are forty-five species, of which the following are principally deserving of notice.

Viverra, *ichneumon*, or the ichneumon, of which there are two varieties, the Indian and the Egyptian. The Egyptian ichneumon is nearly three feet and a half in full length, and of a pale reddish grey colour. It bears a mortal enmity to rats, and snakes, and other offensive animals, with which Egypt is infested, and is domesticated frequently in that country for the sake of its services on this account.

Viverra, *striata*, is a native of Mexico, and discriminated by five longitudinal stripes of white on its back of chocolate colour. When irritated by fear or anger it emits a vapour extremely fetid, in comparison with which every other odour, generally deemed repulsive and disgusting, is pronounced to be the most exquisite perfume.

Viverra, *civetta*, or the civet, is a native of the warm territories of Asia and Africa, and above two feet long, exclusively of the tail. It subsists on smaller quadrupeds and birds. This animal is distinguished for its perfume, for which it was well known to the ancients, who considered it as one of the most powerful stimuli, and for which it is kept in a state of confinement in Holland at the present day, as well as in the East. The drug produced by the civets is formed in a glandular receptacle, and is taken from it by its keeper several times in the course of a week; the quantity generally procured from each civet at a time being about a drachm, but varying with the state of the animal's health, and the nourishing quality of its food.

Vivera, *furor*, or the ferret, resembles the pole-cat both in form and manners. It is a native of Africa, whence it is stated to have

been imported into Spain for the destruction of the rabbits, which had multiplied in that country to the most injurious excess. It was thence introduced into other European countries, but is ill adapted to endure the rigours of a northern winter, being particularly susceptible of cold.

Viverra, *vulgaris*, or the common weasel, is about nine inches long, including the tail, is elegant in its appearance, and light in its movements, but unpleasant by the odour which accompanies it. It dwells under the roots of trees, and subsists on field mice, small birds, and even young rabbits. It is also particularly fond of eggs. It is often fatal to the hare itself, which appears to entertain for the weasel extreme terror, and to be overwhelmed at the sight of it into a complete incapacity for resistance. It is a more formidable enemy to rats and mice than even the cat itself, as it has greater facility for pursuing them to their retreats, and on this account it is much valued and encouraged by the farmer. Its bite is said to be almost certainly, though not always immediately fatal.

VIVIPAROUS, in natural history, an epithet applied to such animals as bring forth their young alive and perfect, in contradistinction to them that lay eggs, which are called oviparous animals.

ULLAGE, in gauging, is so much of a cask, or other vessel, as it wants of being full. See Gauging.

ULMUS, a genus of plants of the class pentandria, and order digynia, and in the natural system arranged under the 53d order, scabridæ. There are six species, two of which are natives of Britain, viz. the campestris, common elm, and the montana, or wych elm. All the sorts of elm may be either propagated by layers or suckers taken from the roots of the old trees, the latter of which is generally practised by the nursery gardeners. The elm delights in a stiff, strong soil. It is observable, however, that here it grows comparatively slow. In light land, especially if it is rich, its growth is very rapid; but its wood is light, porous, and of little value, compared with that which grows upon strong land, which is of a closer, stronger texture, and at the heart will have the colour, and almost the heaviness and the hardness, of iron. On such soils the elm becomes profitable, and is one of the trees which ought, in preference to all others, to engage the planter's attention.

ULVA, a genus of plants of the class cryptogamia, and order of algæ. The fructification is inclosed in a diaphanous membrane. There are 26 species of British plants. They are all sessile, and without roots, and grow in ditches, and on stones along the sea-coast.

UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like an umbrella, on each little subdivision of which there is growing a small flower; such are fennel, dill, &c.

UMBER, or Umbre, *umbria*, among painters, &c. a kind of dry dusky-coloured earth, which, diluted with water, serves to make a dark brown colour, usually called with us a hair colour.

UNCIA, in general, a Latin term denoting the twelfth part of any thing, particularly the twelfth part of a pound, called in English an ounce; or the twelfth part of a foot, called an inch.

UNCIÆ, in algebra, the numbers prefixed before the letters of the members of any power produced from a binomial, residual, or multinomial root. Thus, in the fourth power of $a + b$, viz. $a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$, the unciæ are 4, 6, and 4, being the same with what others call co-efficients.

UNDULATION, in physics, a kind of tremulous motion or vibration observable in a liquid, whereby it alternately rises and falls like the waves of the sea. Thus undulatory motion, if the liquid be smooth and at rest, is propagated in concentric circles, as most people have observed upon throwing a stone, or other matter, upon the surface of a stagnant water, or even upon touching the surface of the water lightly with the finger, or the like.

UNGULA, in geometry, the section of a cylinder cut off by a plane passing obliquely through the plane of the base and part of the cylindric surface.

UNITARIANS, in church history, are those who believe that there is but one God, the supreme object of religious worship; and that this God is the Father only, and not a Trinity consisting of Father, Son, and Holy Ghost. The prime article in the system of this religious body is, that Jesus Christ was a mere man, and that therefore worship addressed to him is idolatry.

UNIVALVE *shells*, in natural history, a term used to express one of the three general classes of shell-fish; the other two being the bivalves and multivalves.

UNIVERSALISTS, those who hold that all future punishment is designed for correction; and that, consequently, all rational beings will be ultimately rendered happy by the God of love and mercy.

UNIVERSITY. This term signifies the establishment of many colleges in one particular situation, all of which are subject to the same general government, and which are formed by the residence of numerous professors in every branch of science, who teach them to students assembled from all parts of Europe, and particularly the countries possessing those seats of learning.

VOLCANO, in natural history, a burning mountain, or one that occasionally vomits forth fire, flame, ashes, cinders, &c. Volcanoes are peculiar to no climate, and have no necessary connection with any other mountains, but seem to have some with the sea, being generally in its neighbourhood; they frequently throw out matters which belong to the sea, as the relics of fishes, sea-weed, and sometimes sea-water itself. The most celebrated volcanoes are those of Ætna and Vesuvius.

The combustion of those enormous masses of bitumen, which are deposited in the bowels of the earth, produces volcanoes. They owe their origin more especially to the strata of pyritous coal. The decomposition or action of water upon the pyrites determines the heat, and the production of a great quantity of hydrogen, which exerts itself against the surrounding obstacles, and at length breaks them. This effect appears to be the chief cause of earthquakes; but when the concourse of air facilitates the combustion of the bitumen and the hydrogen, the flame is seen to issue out of the chimneys or vents which are made: and this occasions the fire of volcanoes.

As volcanoes exist in our earth, there is every

reason to believe that they exist also in other earths. An appearance of this kind was discovered some years ago by Don Ulloa in an eclipse of the sun. It was a small bright spot, like a star, near the margin of the moon, and which he at that time supposed to have been a hole, with the sun's light shining through it. Succeeding observations, however, have induced astronomers to attribute appearances of this kind to the eruption of volcanic fire; and Dr. Herschel has particularly observed several eruptions of the lunar volcanoes, the last of which he gives an account of in the Philosophical Transactions for 1787.

VOLVOX, in zoology, a genus of animals belonging to the order of vermes infusoria. The body is round, simple, and pellucid. There are ten species, all of which live in water.

VOLUTA, in natural history, a genus of animals belonging to the class and order of vermes testacea. There are 144 species.

VOLUTE, a spiral scroll, used in the Ionic and Composite capitals, whereof it makes the principal characteristic and ornament. See Architecture.

VOMITING. See Medicine.

VORTEX, in the Cartesian philosophy, is a system or collection of particles of matter moving the same way, and round the same axis.

VORTICELLA, a genus of vermes infusoria. The generic character is, body contractile, naked, and furnished with ciliate rotatory organs. There are nearly sixty species of this genus.

VOWEL, in grammar, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard, and to form a distinct voice. See Grammar.

The vowels are six in number, viz. A, E, I, O, U, Y, and are called vowels in contradistinction to certain other letters, which depending on a particular application of some part of the mouth, as the teeth, lips, or palate, can make no perfect sound without [illegible] opening of the mouth, that is, without the addition of a vowel, and are therefore called consonants.

UPUPA, in ornithology, a genus belonging to the order of picæ. The beak is arcuated, convex, and something blunt; the tongue is obtuse, triangular, entire, and very short; and the feet are fitted for walking. There are ten species, one of which, the epops, hoopoe, or dung-bird, is frequently seen in Britain.

URANAIUM. See Chemistry.

URANOSCOPUS, star-gazer, a genus of fishes of the order jugulares. The generic character is, head large, depressed, rough; mouth furnished with an internal cirrus; gill-covers edged by a ciliated border gill-membrane five-rayed. There are only two species.

UREA, the constituent and characteristic matter of urine, may be obtained by the following process:—Evaporate by a gentle heat a quantity of human urine, voided six or eight hours after a meal, till it is reduced to the consistence of a thick syrup. In this state, when put by to cool, it concretes into a crystalline mass. Pour at different times upon this mass four times its weight of alcohol, and apply a gentle heat; a great part of the mass will be dissolved, and there will remain only a number of saline substances. Pour the alcohol solution into a retort, and distil by the heat of a sand-bath till the liquid, after boiling some time, is reduced to the consistence of a thick syrup. The whole of the alcohol is now separated, and what remains in the retort crystallizes as it cools. These crystals consist of the substance known by the name of urea.

URIC *acid*. This acid was discovered by Scheele in the year 1776. It was at first called lithic acid. It constitutes one of the component parts of urinary calculi, and is also found in human urine. There is one species of calculus which is almost entirely composed of this substance; it is that species which resembles wood in appearance and colour. This acid is insipid, inodorous, almost insoluble in cold water, and soluble only in about 360 parts of boiling water.

URINE. This excrementitious fluid, in its natural state, is transparent, of a yellow colour, a peculiar smell, and saline taste. Its production, as to quantity, and in some measure quality, depends on the seasons, and the peculiar constitution of the individual, and likewise modified by disease. It is observed, that perspiration carries off more or less of the fluid, which would else have passed off by urine; so that the profusion of the former is attended with a diminution of the latter.

From the alkaline smell of urine kept for a certain time, and other circumstances, it was formerly supposed to be an alkaline fluid; but by its reddening paper stained blue with litmus or the juice of radishes, it appears to contain an excess of acid.

Urine soon undergoes spontaneous changes, which are more or less speedy and extensive, according to its state, as well as the temperature of the air. Its smell, when fresh made, and healthy, is somewhat fragrant; but this presently goes off, and is succeeded by a peculiar odour termed urinous. As it begins to be decomposed, its smell is not very unlike that of sour milk; but this soon changes to a fetid, alkaline odour. It must be observed, however, that, turpentine, asparagus, and many other vegetable substances, taken as medicine, or used as food, have a very powerful effect on the smell of the urine. Its tendency to putrefaction depends almost wholly on the quantity of gelatin and albumen it contains; in many cases, where these are abundant, it comes on very quickly indeed.

Urine has been employed for making phosphorus, volatile alkali, and sal ammoniac; moulds to the produce of nitre beds; and it is very useful in a putrid state for scouring woollens.

URSA, the *bear*, in astronomy, a name common to two constellations of the northern hemisphere, near the pole, distinguished by major and minor.

URSUS, *bear*, a genus of quadrupeds of the order feræ: the generic character is, front teeth six both above and below: the two lateral ones of the lower jaw longer than the rest, and lobed; with smaller or secondary teeth at their internal bases; canine teeth solitary; grinders five or six on each side, the first approximated to the canine teeth; tongue smooth; snout prominent; eyes furnished with a nictitating membrane. There are ten species.

Ursus, *arctus*, the brown bear, is met with in almost all the northern territories of Europe and Asia, and lives solitary in remote forests,

subsisting principally on fruits and other vegetable substances, and occasionally devouring animals. It is particularly fond of honey, and is said to possess great sagacity in discovering it; and will ascend high trees to obtain it. It frequently resides in the hollows of trees, and sometimes fixes its habitation in the banks of rivers, for the sake of fish, which it sometimes takes and devours. Towards the close of autumn, it retires to its habitation in a state highly fleshy and fat, and remains for weeks together without food, and almost without motion.

Ursus *Americanus*, or the American bear, has a long pointed nose, and is generally smaller than the above species. It abounds in the northern territories of America, and is said to live exclusively on vegetable food, extreme hunger only being able to induce it to eat the flesh of animals. These bears reside in trees, mounting and descending them with great alertness. Their skins form an important article of merchandize; their flesh, when young, is thought delicious; and their fat is thought an admirable application for sprains and bruises. They are taken frequently by setting fire to the trees which they inhabit.

Ursus *maritimus*, or the Polar bear, is nearly double the size of the common bear, and is stated to have been seen of the length of twelve feet. It is completely white. Its principal residence is on the shores of Greenland and Hudson's Bay, and it inhabits only the coldest regions of the world. It possesses the most formidable strength and ferocity. They subsist on fishes, seals, and whales, at sea; and by land devour birds, hares, deer, and various other animals; and will also eat berries and various other vegetables. In Greenland they sometimes surround the habitations of the natives, allured by the strong smell of the seal oil, and attempt to break through to commit their depredations; but are reported to be effectually repelled by the smell of burnt feathers. In winter they ingulph themselves in the snow, or immure themselves in some cavern, where they pass in torpor the Polar night, making their egress only with the re-appearance of the sun: in summer they are often found on large masses of floating ice at sea, and, swimming with great excellence, they pass from one of these to another with much facility.

Ursus *meles*, the badger, is an inhabitant of all the temperate parts of Europe and Asia. Its usual length is about two feet from the nose to the tail, which measures six inches. It is an animal of very clumsy make, being thick-necked and thick-bodied, with very short legs. It commonly resides in a hole or den under ground, out of which it emerges by night in quest of food; feeding chiefly on roots and fruits; but it will also devour frogs, worms, &c.

URTICA, a genus of plants of the class monoecia, and order tetrandria; and in the natural system classed under the 53d order, scabridæ. The male flower has a calyx of four leaves; no corolla; a nectarium minute, central, urn-fashioned. The female a bivalve calyx; and a single, oval, glossy seed. There are 59 species, three of which are British plants.

Nettle-tops in the spring are often boiled and eaten by the common people instead of cabbage-greens. In Arran, and other islands, a rennet is made of a strong decoction of nettles: a quart of salt is put to three pints of the decoction, and bottled up for use.

USANCE, in commerce, is a determinate time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called because regulated by the usage and custom of the places whereon they are drawn.

USHER, an officer, or servant, who has the care and direction of the door of a court, hall, chamber, or the like.

Usher *of the Black Rod*, the eldest of the gentlemen-ushers daily waiters at court, whose duty is to bear the rod before the king at the feast of St. George, and other solemnities: he has also the keeping of the chapter-house door, when a chapter of the order of the garter is sitting, and in time of parliament attends the house of peers, and takes delinquents into custody. He wears a gold badge, embellished with the ensigns of the order of the garter.

USURY, in a strict sense, is a contract upon the loan of money, to give the lender a certain profit for the use of it, upon all events, whether the borrower made any advantage of it, or the lender suffered any prejudice for the want of it, or whether it be repaid at the appointed time or not; and in a large sense, it seems, that all undue advantages taken by a lender against a borrower, come under the notion of usury.

VULGATE, a very ancient Latin translation of the bible, and the only one the church of Rome acknowledges authentic. See Bible. The ancient vulgate of the old testament was translated almost word for word from the Greek of the LXX. The author of the version is not known, nor so much as guessed at.

Vulgate *of the New Testament*. This the Romanists generally hold preferable to the common Greek text, in regard it is this alone, and not the Greek text, that the council of Trent had declared authentic. Accordingly that church has, as it were, adopted this edition. The priests read no other at the altar, the preachers quote no other in the pulpit, nor the divines in the schools.

VULTUR, the *vulture*, in natural history, a genus of birds belonging to the order of accipitres. The beak is straight, and crooked at the point; the head has no feathers, on the forepart there being only naked skin, and the tongue is generally bifid. There are twenty-one species. The most remarkable are,

Vultur gryphus, or the condor vulture, is found particularly in South America, and from point to point of its wings is of the width of twelve feet. The feathers of its back are of a brilliant black. Its quill feathers are more than two feet and a quarter in length, and are half an inch in diameter.

Vultur harpya, or the crested vulture, is rather larger than a turkey, and is distinguished by a crest of four feathers on its head. Its strength is extraordinary, and with a single stroke of its bill it is reported to be able to cleave down the skull of a man. It is found in Mexico and Brazil.

Vultur aura, or the carrion vulture, is of the same size as the last, is common both in North and South America, and feeds on carcases and on snakes. Its odour is particularly rank. It is far from being ferocious and dangerous, may

be easily reared tame, and is considered in the West Indies as highly useful in destroying reptiles, vermin, and carrion, insomuch that the killing of them is prohibited by law. They roost together at nights in considerable numbers, in the manner of rooks.

Vultur sagittarius, or the secretary vulture, is distinguished by the extraordinary length of its legs, and when standing upright is a yard high. It is found in Africa, and in the Philippine Islands. It principally lives on lizards and rats, and various species of vermin. It strikes with its feet forwards, and never the contrary. It takes up tortoises in its claws, and dashes them with great force on the ground, and will repeat this process till these animals are completely killed.

UVULARIA, a genus of the hexandria monogynia class of plants, the flower of which consists of six very long lanceolated petals; and its fruit an ovate-oblong trilocular capsule, containing several roundish and compressed seeds. There are six species.

W.

W, or w, is the twenty-first letter of our alphabet, and is composed, as its name implies, of two v's. It was not in use among the Hebrews, Greeks, or Romans, but chiefly peculiar to the northern nations, the Teutones, Saxons, Britons, &c.

WACHENDORFIA, a genus of plants of the class triandria, and order monogynia; and arranged in Linnæus's natural method of classification under the 6th order, ensatæ. The corolla is hexapetalous, unequal, and situated below the germen; the capsule trilocular and superior. There are five species, none of which are natives of Britain.

WACKE, a mineral substance intermediate between clay and basalt. It is sometimes simple; but when it inclines to basalt, it contains hornblende and mica. It is sometimes spotted, and these spots are unformed crystals of hornblende, resembling the unformed crystals of felspar in certain varieties of porphyry. It never contains augite or olivine. When it approaches to an amygdaloid, it is vesicular. Its colour is greenish-grey. Massive and vesicular. Dull. Opaque. Streak shining. Soft. Easily frangible. Specific gravity 2.55 to 2.9. Fuses like basalt.

WADD, or WADDING, is a stopple of paper, hay, straw, or the like, forced into a gun upon the powder to keep it close in the chamber; or to put up close to the shot to keep it from rolling out.

WADD. This name is given to plumbago, or black-lead.

WADD, *black*. An ore of manganese found in Derbyshire. It is remarkable for the property of taking fire when mixed with linseed oil.

WAFERS are made thus: take very fine flour, mix it with glair of eggs, isinglass, and a little yeast; mingle the materials; beat them well together, spread the batter, being made thin with gum water, on even tin plates, and dry them in a stove; then cut them out for use. You may make them of what colour you please, by tinging the paste with brazil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAGER of law is a particular mode of proceeding, whereby, in an action of debt, brought upon a simple contract between the parties, without any deed or record, the defendant may discharge himself by swearing in court, in the presence of compurgators, that he owes the plaintiff nothing, in manner and form as he has declared, and his compurgators swear, that they believe what he says is true. And this waging his law is sometimes called making his law. It being at length considered, that this waging of law offered too great a temptation to perjury, by degrees new remedies were devised, and new forms of action introduced, wherein no defendant is at liberty to wage his law, as in assumpsit and trover.

WAGERS. In general a wager may be considered as legal, if it is not an incitement to a breach of the peace, or to immorality; or if it does not affect the feelings or interest of a third person, or expose him to ridicule: or if it is not against sound policy.

WAGES, what is agreed upon by a master to be paid to a servant, or any other person that he hires to do his business for him.

WAGTAIL, in ornithology. See MOTACILLA.

WAIFS. See ESTRAYS.

WAKE *of a ship*, is the smooth water astern when she is under sail. This shows the way she has gone in the sea, whereby the mariners judge what way she makes. For if the wake be right a-stern, they conclude she makes her way forwards; but if the wake be to leeward a point or two, then they conclude she falls to the leeward of her course.

WALE, or WALES, in a ship, those outermost timbers in a ship's side on which the sailors set their feet in climbing up. They are reckoned from the water, and are called her first, second, and third wale, or bend.

WALRUS. See TRICHECHUS.

WALNUT-*tree*. See JUGLANS.

WALTHERIA, a genus of the monadelphia pentandria class of plants, the flower of which consists of five petals, vertically cordated and patent; the fruit is an unilocular bivalve capsule, vertically ovated; and the seed is single, obtuse, and broadest at the top. There are six species.

WAPENTAKE, from the Saxon, the same with what we call a hundred, and more especially used in the northern counties beyond the river Trent.

WAR. The too frequent recurrence of this great and detestable calamity, unfortunately renders a definition of the word unnecessary. If we were called upon to define it, we should say, it is the wanton destruction, the cold-blooded slaughter, of the human race: we should call it an accumulation of every sin that degrades and vilifies mankind: we should mark it as a practice that diffuses misery and

perpetuates vice: we should say, that if there is a burlesque upon the boasted reason of man, it is this; when millions meet to murder each other for a quarrel in which, in general, they have not individually the smallest interest. The poet who wrote,

> "One murder makes a villain, millions a hero," &c.

deserves a statue of gold; and the writer of that verse may lift his head in the proudest assembly, and avow his principles in the face of the world.

WARD, in law-books, a word of divers significations; thus, a ward in London, is a part of the city committed to the special charge of one of the aldermen of the city.

WARDEN, one who has the charge or keeping of any person, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet-prison; who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

WARDMOTE, in London, is a court so called which is kept in every ward of the city, answering to the curiata comitia in ancient Rome.

WARNING WHEEL, in a clock, is the third or fourth, according to its distance from the first wheel. See CLOCK-WORK.

WARP, in the manufactures, is the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman by means of his shuttle passes the threads of the woof, to form a cloth, ribband, fustian, or other stuff.

WARRANT, a præcipe, under hand and seal, to some officer, to bring any offender before the person granting it; and warrants of commitment are issued by the privy council, a secretary of state, or justice of peace, &c. where there has been a private information, or a witness has deposed against an offender. Any one under the degree of nobility may be arrested for a misdemeanor, or any thing done against the peace of the kingdom, by warrant from a justice of the peace; though if the person be a peer of the realm, he must be apprehended for a breach of the peace by warrant out of the King's Bench.

WARRANT *of attorney*, is an authority and power given by a client to his attorney, to appear and plead for him; or to suffer judgment to pass against him by confessing the action, by nil dicit, non sum informatus, &c.

WARRANTY, a promise or covenant by deed, made by the bargainer, for himself and his heirs, to warrant or secure the bargainee and his heirs against all men, for the enjoying any thing agreed on between them.

WARREN, a franchise, or place privileged either by prescription or grant from the king, to keep beasts and fowl of warren in; as rabbits, hares, partridges, pheasants, &c.

WASH, among distillers, the fermentable liquor used by the malt distillers.

WASP. See VESPA.

WASTE, is the committing any spoil or destruction in houses, lands, &c. by tenants, to the damage of the heir, or of him in reversion or remainder; whereupon the writ or action of waste is brought for the recovery of the thing wasted, and damages for the waste done.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrol. At sea, the term denotes a space of four hours.

WATCH, strictly speaking, is a term denoting all such movements as shew the parts of time; and clocks are such as publish it, by striking a bell. But the name watch is commonly appropriated to such machines of this kind as are carried in the pocket; and clock to the larger movement whether they strike or not.

As nothing has been said on the construction of either of these machines, either under the article *clock*, or that of *horology*, a brief description of both shall now be given. By referring to the plates the reader will readily comprehend the nature of this beautiful and useful mechanism.

Fig. 1, Plate LI, exhibits a profile view of an eight-day clock, with repeating, striking mechanism. To this figure, and to figure 2, the letters are common; *a*, is the barrel of the going part, having a band of catgut *b* wound round it, and to which the weight which keeps the clock going, is suspended; 96 is a wheel, called the great, or first wheel, having that number of teeth, upon the end of the barrel, turning a pinion of eight leaves, on an arbour which carries the minute-hand. 64, is a wheel of 64 teeth on the same arbour, turning the wheel 60 by a pinion of eight leaves on its arbour; this gives motion to the pinion of eight, on the arbour of the swing wheel 30, of 30 teeth; *d, h*, are the pallets of the escapement fixed on an arbour *e*, fig. 1, going through the back plate of the clock's frame, and carrying a long lever *f*; this lever has a small pin projecting from its lower end, going into an oblong hole, made in the rod B of the pendulum. The pendulum consists of an inflexible metallic rod, suspended by a very slender piece of steel-spring, D, from a brass bar, E, screwed to the frame of the clock, having a weight at its lower end; when this pendulum is moved from the perpendicular line in either direction, and suffered to fall back again, it swings nearly as much beyond the perpendicular on the contrary side, and then returns; this it will continue to do for some time, and each of these vibrations will be performed in one second of time. This is the measurer of the time; and the office of the clock is only to indicate the number of vibrations it has made, and give it a small impulse each time to keep it going, as the resistance of the air and elasticity of the spring D would otherwise in a few hours cause it to stop. By the action of the weight applied to the cord *b*, the wheels are all turned round, and if the pallets *d, h* were removed, the swing wheel 30 would revolve with great velocity in the direction from 30 to *d*, until the weight reached the ground; the teeth of these pallets are so made that one of them always engages the wheel, and prevents it turning more than half a tooth at a time. The pinion of eight on its arbour is turned by a wheel of 60, which consequently will turn once in seven turns and a half of the other, or in seven minutes 30 seconds, or one-eighth of an hour; its pinion of eight is moved by a wheel of 64, or eight times itself, which will turn in one-eighth part of the time, this will be an hour; the arbour of this wheel therefore carries the minute hand of the clock. The great wheel of 96, being 12 times the number

of the pinion eight, will turn once in 12 hours, and the barrel *a* with it. The gut goes round 16 times, so that the clock will go eight days. The hour-hand of the clock is turned by the wheel-work shewn in fig. 3: on the end of the arbour of the centre-wheel 64 a tube is fitted, so as to go round with it by friction; this carries the minute hand, but if the clock should require correction, the hand may be slipped round without moving the wheels: this tube has a pinion of 40 teeth on its lower end, indicated by a dotted circle: this turns another wheel 40, of 40 teeth, which has a pinion of six teeth on its arbour, turning a wheel 72, of 72 teeth; the two wheels 40 will both turn in an hour; and 72 in 12 hours: the arbour of this wheel has the hour-hand. and is a tube going over the arbour of the minute-hand, so that the two hands are concentric.

The barrel *a* is fitted to an arbour coming through the plate of the clock, and. is filed square to put on a key to wind up the weight; the great wheel 96 is not fixed fast to the arbour, but has a click on it, which takes the teeth of a rachet wheel cut upon the barrel; so that the barrel may be turned in the direction to wind up the weight without the wheel; but by the descent of the weight, the wheels will be turned by the click.

Having now described the going part of the clock, it remains to describe the mechanism by which the hours are struck. 78, fig 2, is a great wheel of 78 teeth, with a barrel and click the same as 96; it turns a pinion of eight; 64 is a wheel on the same arbour, turning a pinion of eight on the arbour of the wheel *o* of 48, this turns another pinion of eight, and wheel *p* of 48, which turns a pinion of six, on the same arbour with a thin vane of metal, which is called the fly, and by the resistance of the air to its motion, regulates the velocity of the wheels. The wheel 64 has eight pins projecting from it, these raise the tail *n* of the hammer, as they revolve; the hammer is returned violently when the pins leave its tail, by a spring *m* pressing on the end of a pin put through its arbour, and strikes the bell, *l* is a short spring which the other end of the pin through the arbour touches, just before the hammer strikes the bell, its use is to lift the hammer off the bell the instant it has struck, that it may not stop the sound. The eighth pin in the wheel 64 must pass by the hammer tail 78 times in striking the 12 hours, $1 + 2 + 3 + 4 + 5 + 6 + 7 + 8 + 9 + 10 + 11 + 12 = 78$, and as its pinion has eight leaves, each leaf of the pinion answers to a pin in the wheel 64; now as the great wheel has 78 teeth, it will turn once in 12 hours, the same as the other great wheel 96. In the wheel 64 eight of its teeth correspond to one of the pins for the hammer, and as the pinion of the wheel *o* has eight teeth, it will turn once for each stroke of the hammer. By the remaining wheels, one, *o* multiplying six, and the other, *p*, eight times, the fly will turn $6 \times 8 = 48$ times for one turn of $o =$ one stroke of the hammer. Fig. 3 is also mechanism relating to the striking part: *r* is a small pinion of one tooth, called the gathering pallet, on the arbour of wheel *o*, and consequently turns once for each stroke of the hammer, *s* is a segment of a large wheel which it turns, (called the rack): *t* is an arm attached to the rack, whose end rests against the spiral plate, V, called the snail; this is fixed on the tubular arbour before described, of the hour hand and wheel 72, and turns round with it once in twelve hours. The plate is divided into twelve equal angles, 30 degrees each, and as it turns each of these answers to an hour. The circular part of the rack *s* is cut into teeth each of which is of such a length, that every step upon the snail shall answer to one of them; *w* is a spring pressing against the tail of the rack, and acting to throw the arm of the rack against the snail; *g* is a click or hawk's bill, taking into the teeth of the rack, and holding it up in opposition to the spring *w*; *i k* is a three-armed detent, called the warning-piece, the arm *k* is bent at its end, and passes through a hole in the front plate of the clock, so as to catch a pin placed in one of the arms of the wheel *p*, fig. 2, and which describes the dotted circle in fig. 3, the other arm *i* stands so as to fall in the way of a pin in the wheel 40. The wheel 40, turns once in an hour, and consequently at the expiration of every hour the pin in it takes the end *i*, and moves it towards the spring near it, this depresses the end *k* until it falls in the circle of the motion of the pin in the wheel *p*, fig. 2, at the same time the short tail depresses one end of the hawk's bill, and raises the other *g*, so as to clear the teeth of the rack *s*; immediately the spring *w* throws the rack back, until the end of its tail *t* touches that part of the snail which is nearest it; when the rack falls back, the pin in it is moved clear of the gathering pallet *r*, and the wheels set at liberty; the maintaining power puts them in motion; but in a very short time before the hammer has struck, the pin in the wheel *p* falls against the end of *k* and stops the whole: this operation happens a few minutes before the clock strikes, and this noise of the wheels turning is called the warning; when the hour is expired, the wheel 40 has turned so far as to allow the end of *t* to slip over its pin, as in the figure: the small pin pressing against it raises the end *k* so as to be within the circle of the pin in the wheel *p*, fig. 2: every obstacle is now removed, and the wheels run on the pinion; the wheel 64 raises the hammer *r*, and it strikes on the bell, the gathering palate *r*, and takes up the rack, a tooth at each turn, the hawk's bill *g* retaining it until the pin in the rack comes under the gathering palate *r*, and stops the motion of the whole machine, till the pin in the wheel 40 at the next hour takes the warning piece *i k*, and repeats the operation we have now described. As the gathering pallet turns once for each blow of the hammer, and its tooth gathers up one tooth of the rack at each turn, it is evident the number of teeth the rack is allowed to fall back limits the number of strokes the hammer will make. This is done by the rack's tail *t* resting on the snail; each step of the snail answers to one tooth of the rack, and one stroke of the hammer.

Plate LII, exhibits the principal parts of the mechanism of a common pocket watch.

The moving power is a spiral steel spring fig 3, which is coiled up close by a tool for the purpose, and put into a brass box, fig. 2, called the barrel: the spring has a hook at its outer end, which is put through a hole in the side of the barrel and rivetted; the inner end has an oblong opening cut through it, to receive a hook upon the barrel arbour, fig. 6. This arbour goes

through the bottom of the barrel, and is square to hold a worm-wheel *d*, fig. 5, which is turned round by a worm *b*; the ends of the arbour project below this, and it is pivoted into the lower plate A, fig. 8, of the watch; the top of the barrel has a cover put over it, through which the pivot of the arbour projects, and works in a socket in the upper plate D.

The barrel thus mounted has a steel chain *a*, figs. 1 and 8, hooked to its upper end, and coiled round it; the other end of this chain is hooked to the lower part of the fusee, figs. 1 and 8. It is evident, that when the fusee is turned by the watch key, it will wind the chain off the barrel on itself; and as one end of the spring is fastened to the barrel, and the other is hooked to the arbour (which is prevented from turning by the worm-wheel beneath,) the spring will be coiled up into a smaller compass than it was before; and by its re-action will, when the watch-key is taken off, turn the fusee, and keep the watch going. The fusee has a spiral groove cut round it, as shewn in fig. 4, in which the chain lies: this groove is cut by an engine, so that the chain shall pull from the smallest part of the fusee, when the spring is wound up, and act with its greatest force; and gradually increases in size as the spring unwinds, and acts with less power; so that the effect upon the great wheel *c*, figs. 1, 8, and 7, may be always the same, and cause the watch to go with regularity; and this effect can be at any time increased or diminished by turning the worm *b*, fig. 5, which coils the spring up closer, and causes it to act with greater force, or vice versa.

The fusee, fig. 4, has a ratchet wheel, at its lower end, which takes into a click fixed in a hollow cut in the great wheel, fig. 7, in order that when the watch is winding up, the fusee may slip round without the great wheel; and that when the spring draws it round in the other direction, it may move the great wheel with it, and the other wheels of the watch.

The great wheel *c* has 48 teeth, on its circumference, which take into and turn a pinion of 12 teeth, fixed on the same arbour with the centre wheel *b*, and fig. 9, which has 54 teeth to turn a pinion of six leaves on the arbour of the third wheel *h*, and fig. 10; the third wheel has 48 teeth, and turns a pinion of six on the arbor of the contrate wheel *i*, and fig. 11, which has 48 teeth cut parallel to its axis, by which it turns a pinion of six leaves, fixed to the balance-wheel *k*, figs. 8, 12, and 14. The pivots of the arbour of this wheel turn, one into a frame F, fig. 14, called the pottance, fixed to the upper plate; and the other in a small piece fixed to the upper part, called the counter pottance, so that when the two plates are put together, the balance-wheel pinion may work in the teeth of the contrate wheel. The balance wheel has 15 teeth, by which it impels the balance *l*, figs. 8, 13, and 15; the arbor of the balance, which is called the verge, has two pallets projecting from it nearly at right angles to each other; these are acted upon by the balance wheel, as shewn in fig. 14, where the lower pallet is supposed to be in contact with one of the teeth of the balance wheel, which, as it turns round, pushes the pallet round and the balance with it, till the balance has made about a quarter of a turn; the tooth of the balance wheel then slips off, and escapes. In this position the watch would run down, if it were not for the upper pallet at that instant taking another tooth on the opposite side of the balance wheel, which, as it moves in a contrary direction, pushes the balance back again till the tooth escapes the pallet; the lower pallet then engages the wheel as before. But for the better regulation of the time, the balance has a very fine spring *m*, fig. 15, called the pendulum spring, with the inner end fixed to the verge just beneath the balance, and the outer end pinned to a stud fixed to the top of the upper plate of the watch, so that the balance will rest only in one position, and if it is moved either way by the balance wheel, the spring will have a tendency to bring it to the same position again. When the lower pallet, for instance, has just liberated a tooth of the balance wheel, the pendulum spring is strained, and returns the balance to its point of rest instantaneously, the balance wheel following the upper pallet by the action of the main spring; and when the balance wheel comes to push the balance beyond its point of rest the other way, it moves slowly, because it has the elasticity of the pendulum spring to overcome.

It is evident, that by strengthening or weakening the spring, the velocity of the balance can be regulated, which is done by a contrivance shewn in fig. 15, and the under side of it in fig. 16. It is a plate of brass screwed to the top of the upper plate, close under the balance; and at one place it is hollowed out to receive a wheel *n*, which turns a segment of a wheel *p*, called the curb, which moves round in a circular groove: it has a projecting leaf *q*, with a notch in it to receive the pendulum spring; so that by turning the wheel with a key put on a square part of its arbor, the spring is lengthened or shortened, so as to give it a different power, and make the balance vibrate quicker, or slower; the arbour of the wheel *n*, has a dial *r*, fig. 15, upon it, with divisions to set it by. The upper pivot of the verge runs in a cock screwed to the upper plate, as shewn in fig. 8, which covers the balance, and protects it from violence; and the lower pivot works in the bottom of the pottance; the socket for the pivot of the balance wheel is made in a small piece of brass, which slides in a groove made in the pottance, as shewn in fig. 14; so that by drawing the slide in or out, the teeth of the balance wheel shall just clear one pallet before it takes the other.

The watch is so adjusted by the pendulum spring, that the balance shall vibrate so as to turn the centre wheel round once in an hour: the spindle of this projects through the lower plate, fig. 8, and has a tube fitted on it, which is square at the top, and carries the minute hand; the other end of this tube has a pinion of 12 teeth on it, which turns the minute wheel *s*, figs. 8 and 17, of 48, and its pinion of 16, which moves the hour wheel *t*, of 48 teeth: the spindle of this is a tube, which is put over the tube of the minute hand, and has the hour hand fixed on it to indicate the time upon the dial-plate.

WATER. It is scarcely necessary to give any definition or description of this universally known fluid. It is a very transparent fluid, possessing a moderate degree of activity with regard to organized substances, which renders

it friendly to animal and vegetable life, for both which it is indeed indispensably necessary. Hence it acts but slightly on the organs of sense, and is therefore said to have neither taste nor smell. It appears to possess considerable elasticity, and yields in a perceptible degree to the pressure of air in the condensing machine, as Canton proved, by including it in an open glass vessel with a narrow neck.

The solubility or insolubility of bodies in this fluid composes a large part of the science of chemistry.

Native water is seldom, if ever, found perfectly pure. The waters that flow within or upon the surface of the earth, contain various earthy, saline, metallic, vegetable, or animal particles, according to the substances over or through which they pass. Rain and snow waters are much purer than these, although they also contain whatever floats in the air, or has been exhaled along with the watery vapours.

WATER-BAILIFF, is an officer in seaport towns, appointed for the searching of ships; and in London, the water-bailiff hath the supervising and search of fish, brought thither, and the gathering of the toll arising from the Thames; his office is likewise to arrest men for debt, &c. or other personal or criminal matters upon the river Thames.

WATER-COLOURS. The general or simple colours, and the various species of each, fit for painting in water-colours, are as follow:

Whites.

Ceruse
Constant white
White lead
Spanish white
Flake white
Spodium.

Blacks.

Burnt cherry stones
Ivory black
Keating's black
Lamp black.

Greens.

Green bice
Green verditer
Grass green
Sap green
Verdigrise distilled.

Blues.

Sanders blue
Terre blue
Blue verditer
Indigo
Litmus
Smalt
Prussian blue
Light ditto
Ultramarine
Ultramarine ashes
Blue bice.

Browns.

Spanish brown
Spanish liquorice
Umber
Bistre
Burnt Terra de Sienna
Unburnt ditto.

Reds.

Native cinnabar
Burnt ochre
Indian red
Red lead
Minium
Lake
Vermilion
Carmine
Red ink
Indian lake.

Yellows.

English ochre
Gall-stone
Gamboge
Masticot
Ochre de luce
Orpiment
Roman ochre
Dutch pink
Saffron water
King's yellow
Gold yellow
French berries.

See Painting.

WATER COURSE. A water course does not begin by prescription, nor assent, but begins ex jure naturæ, having this course naturally; and cannot be diverted.

WATER *of crystallization.* Many salts require a certain proportion of water to enable them to retain the crystalline form, and this is called their water of crystallization. Some retain this so feebly, that it flies off on exposure to the air, and they fall to powder. These are the efflorescent salts. Others have so great an affinity for water, that their crystals attract more from the air, in which they dissolve. These are the deliquescent.

WATERMEN. In London, the lord mayor and court of aldermen have much power in governing the company of watermen, and appointing the fares for plying on the river Thames; and justices for Middlesex, and other adjoining counties, have also power to hear and determine offences, &c.

WATER-SPOUT, an extraordinary aqueous meteor, most frequently observed at sea. It is a truly formidable phenomenon; and is indeed capable of causing great ravages. It commonly begins by a cloud, which appears very small, and which mariners call the squall; which augments in a little time into an enormous cloud of a cylindrical form, or that of a reversed cone, and produces a noise like an agitated sea, sometimes emitting thunder and lightning, and also large quantities of rain or hail, sufficient to inundate large vessels, overset trees and houses, and every thing which opposes its violent impetuosity.

WATER-WORKS, in general, denote all manner of machines moved by, or employed in raising or sustaining water; in which sense water-mills of all kinds, sluices, aqueducts, &c. may be called water-works.

WAX. The upper surface of the leaves of many trees is covered with a varnish, which may be separated and obtained in a state of purity, and is found to possess all the properties of bees' wax: hence it is justly inferred that wax is a vegetable product, and that the bees extract it unaltered from the leaves of trees, and other vegetable substances that contain it. Several plants contain wax in such abundance as to make it worth while to extract it from them.

WAY, a road, or passage. A way may be by prescription, as if the owners and occupiers of such a farm have immemorially used to cross another's ground; for this immemorial usage supplies an original grant. A right of way may also arise by act and operation of law; for if a man grants to another a piece of ground in the middle of his field, he at the same time tacitly gives him a way to come at it, for where the law gives any thing to any person, it gives implied by whatever is necessary for enjoying the same.

Way *of a ship*, is sometimes used for her wake or track. But more commonly the term is understood of the course or progress which she makes on the water under sail: thus when she begins her motion, she is said to be under way.

WEASEL. See Viverra.

WEATHER. See Meteorology.

Weather-glasses, are instruments contrived to indicate the state or disposition of the atmosphere, and the various alterations in the weather: such are barometers, thermometers, hygrometers, &c.

WEAVING, is that art by means of which single threads, whether of cotton, silk, wool, or flax, are formed into a close fabric called cloth. To enter into the complicated mazes of this useful art, would require a volume of no ordinary size. It has somehow happened

that, till very lately, this art has been considered unworthy the notice of any writer who could do it justice; but this defect is amply supplied by the appearance of Mr. Murphy's volume on weaving, to which the reader is referred for all the information respecting the process which he may be in pursuit of. See also Duncan's Essays on the Art of Weaving.

WEDGE, one of the mechanical powers, as they are called. The wedge is a triangular prism, whose bases are equilateral acute-angled triangles. See MECHANICS.

WEEK, in chronology, a division of time comprising seven days. See CHRONOLOGY.

WEIGHT, in physics, is a quality in natural bodies, by which they tend towards the centre of the earth. See GRAVITATION. Weight may be distinguished into absolute, specific, and relative.

WEIGHT, in commerce, denotes a body of a known weight, appointed to be put in the balance against other bodies, whose weight is required.

WEIGHTS, *Modern English*. By the 27th chapter of Magna Charta, the weights all over England are to be the same; but for different commodities, there are two different sorts, viz. troy weight, and avoirdupois weight. The origin from which they are both raised, is a grain of wheat gathered in the middle of the ear.

In troy weight, twenty four of these grains make a pennyweight sterling, twenty pennyweights make one ounce, and twelve ounces one pound.

By this weight we weigh gold, silver, jewels, and liquors. The apothecaries also use the troy pound, ounce, and grain; but they differ from the rest in the intermediate divisions. They divide the ounce into eight drachms, the drachm into three scruples, and the scruple into twenty grains.

In avoirdupois weight, the pound contains sixteen ounces, but the ounce is less by near one-twelfth than the troy ounce, this latter contains 480 grains, and the former only 448. The ounce contains 16 drachms: 80 ounces avoirdupois are only equal to 73 ounces troy, and 17 pounds troy equal to 14 pounds avoirdupois.

By avoirdupois weight are weighed mercury, grocery, wares, base metals, wool, tallow, hemp, drugs, bread, &c.

Table of Troy Weight, as used by the Goldsmiths.

Grains.			
24	Pennyweights.		
480	20	Ounce.	
5760	340	12	Pound.

Apothecaries.

Grains.				
20	Scruple.			
60	3	Drachm.		
480	24	8	Ounce.	
5760	218	96	12	Pound.

Table of Avoirdupois Weight.

Scruples.					
3	Dram.				
24	8	Ounces.			
384	128	16	Pound.		
43008	14336	1792	112	Quintal, or hundred.	
860160	286720	35840	2240	20	Ton.

Mr. Ferguson gives the following comparison between troy and avoirdupois weight:

175 troy pounds are equal to 144 avoirdupois pounds.

175 troy ounces are equal to 192 avoirdupois ounces.

1 troy pound contains 5760 grains.

1 avoirdupois pound contains 7000 grains.

1 avoirdupois ounce contains 437½ grains.

1 avoirdupois dram contains 27.34375 grains.

1 troy pound contains 13 oz. 2.651428576 drams avoirdupois.

1 avoirdupois lb. contains 1 lb. 2 oz. 11 dwts. 16 gr. troy.

Therefore the avoirdupois lb. is to the lb. troy as 175 to 144, and the avoirdupois oz. is to the oz. troy, as 437½ is to 480.

The moneyers, jewellers, &c. have a particular class of weights for gold and precious stones, viz. carat and grain: and for silver, the pennyweight and grain. The moneyers have also a peculiar subdivision of the troy grain: thus, dividing

the grain into 20 mites,
the mite into 24 droits,
the droit into 24 periots,
the periot into 24 blanks.

The dealers in wool have likewise a particular set of weights, viz. the sack, weigh, tod, stone, and clove; the proportions of which are as below, viz.

the sack containing 2 weighs,
the weigh - - - 6½ tods,
the tod - - - - 2 stones,
the stone - - - 2 cloves,
the clove - - - 7 pounds,

Also 12 sacks make a last, or 4363 pounds.

Farther,

56 lb. of old hay, or 60 lb. new hay, make a truss.
40 lb. of straw make a truss.
36 trusses make a load of hay or straw.
14 lb. make a stone.
5 lb. of glass a stone.

WEIGHTS and MEASURES. The standard of measures was originally kept at Winchester, which measure was by the law of king Edgar, ordained to be observed throughout the kingdom. By stat. 35 G. III. c. 102, the justices in quarter-sessions in every county, are required to appoint persons to examine the weights and balances within their respective jurisdictions. These inspectors may seize and examine weights in shops, &c. and seize false weights and balances; and the offender being convicted before one justice, shall be fined

from 5s. to 20s. Persons obstructing the inspectors to forfeit from 5s. to 40s. Inspectors to be recompensed out of the county-rate. Standard weights to be purchased by the sessions out of the county-rate, and produced to all persons paying for the production thereof. Informations to be within one month.

WELD, or **Woald** (reseda luteola, Linn.), is a plant cultivated in Kent, Herefordshire, and many other parts of this kingdom. The whole of the plant is used for dyeing yellow; though some assert, that the seeds only afford the colouring matter.

Two sorts of weld are distinguished: the bastard or wild, which grows naturally in the fields; and the cultivated, the stalks of which are smaller and not so high. For dyeing, the latter is preferred, it abounding more in colouring matter. The more slender the stalk, the more it is valued.

WELDING. Welding is that intimate union produced between the surfaces of two pieces of malleable metal, when heated almost to fusion, and hammered.

WHALE. See Balæna.

Whale fishery. See Fishery.

WHARF, a space on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading of vessels upon.

WHEAT. See Triticum, and Husbandry.

WHEAT-EAR. See Motacilla.

WHEEL, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis. The wheel is one of the principal mechanic powers; it has place in most engines; in effect, it is of an assemblage of wheels that most of our engines are composed.

WHEEL-ANIMALS, *brachionus*, a genus of animalcules which have an apparatus of arms for taking their prey.

WHIRLPOOL, an eddy, vortex, or gulph, where the water is continually turning round. These in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare but more dangerous.

WHIRLWIND, a wind that rises suddenly, is exceedingly rapid and impetuous, in a whirling direction, and often progressively also; but it is commonly soon spent. Dr. Franklin, in his Physical and Meteorological Observations, read to the Royal Society in 1756, supposes a whirlwind and a waterspout to proceed from the same cause: their only difference being, that the latter passes over the water, and the former over the land. This opinion is corroborated by the observations of many others, who have remarked the appearances and effects of both to be the same. They have both a progressive as well as a circular motion; they usually rise after calms and great heats, and mostly happen in the warmer latitudes: the wind blows every way from a large surrounding space, both to the water-spout and whirlwind; and a water-spout has, by its progressive motion, passed from the sea to the land, and produced all the phenomena and effects of a whirlwind; so that there is no reason to doubt that they are meteors arising from the same general cause, and explicable upon the same principles, furnished by electrical experiments and discoveries.

WHISPERING-PLACES depend upon this principle: if the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis, and by that means prevented from spreading, till they get out of it: whereby they will be exceedingly increased, and the sound rendered much louder than it would otherwise be.

WHIST, a well-known game at cards, which requires great attention and silence; hence the name.

WICKLIFFISTS, or *Wicklifites*, a religious sect which sprang up in England in the reign of Edward III. and took its name from John Wickliff, doctor and professor of divinity in the university of Oxford, who maintained that the substance of the sacramental bread and wine remained unaltered after consecration; and opposed the doctrine of purgatory, indulgences, auricular confession, the invocation of saints, and the worship of images. He maintained that children may be saved without being baptised; that priests may administer confirmation; that there ought to be only two orders in the church, that of priests, and that of deacons. He made an English version of the Bible, and composed two volumes, called Alethia, that is, Truth, from which John Huss learned most of his doctrines.

WIDOW, a woman who has lost her husband by death. In London, and throughout the province of York, the widow of a freeman is by custom entitled to her apparel, and the furniture of the bed-chamber, called the widow's chamber.

WIFE. After marriage, all the will of the wife, in judgment of law, is subject to the will of the husband, and it is commonly said a feme coverte has no will.

WILDERNESS, in gardening, a kind of grove of large trees, in a spacious garden, in which the walks are commonly made either to intersect each other in angles, or have the appearance of meanders and labyrinths.

WILL. In the Hartleyan acceptation of the term, the will is that state of mind which is immediately previous to, and causes, those express acts of memory, imagination, reasoning, or bodily motion, which we term voluntary; corresponding to the common acceptation of the term *volition*. In the more customary use of the term, it comprehends the whole class of feelings by which volition is produced.

WILL *and* **TESTAMENT**, in law. Every person capable of binding himself by contract, is capable of making a will. Also a male infant of the age of 14 years and upwards, and female of twelve years and upwards, are capable of making a will respecting personal estates only. But a married woman cannot make a will unless a power is reserved in a marriage settlement; but wherever personal property, however, is given to a married woman for her sole and separate use, she may dispose of it by will. If a feme sole makes her will, and afterwards marries, such marriage is a legal revocation of the will. Wills are of two kinds, written and verbal; the former are most usual and secure. It is not absolutely necessary that a will should be witnessed; and a testament of chattels, written in the testator's own hand, though it should have neither the testator's name

nor seal to it, nor witnesses present at his publication, will be good, provided sufficient proof can be had that it is his hand-writing.

A codicil is a supplement to a will, or an addition made by the person making the same, annexed to, and to be taken as part of, the will itself, being for its explanation or alteration, to add something to, or take something from, the former disposition, and which may also be either written or verbal under the same restrictions as regard wills.

WIND. See METEOROLOGY.

WINDS, *trade*. See METEOROLOGY.

WINDMILL, a kind of mill, the internal parts of which are much the same with those of a water mill; from which, however, it differs in being moved by the impulse of the wind upon its vanes, or sails, which are to be considered as a wheel on the axle.

WINDLASS, or **WINDLACE**, a machine used to raise large weights, as guns, stones, anchors, &c. See MECHANICS.

WIND-SAILS, in a ship, are made of the common sail-cloth, and are usually betwen 25 and 30 feet long, according to the size of the ship, and are of the form of a cone ending obtusely.

WINDWARD, in the sea langrage, denotes any thing towards that point from which the wind blows in respect of a ship: thus, windward tide is the tide which runs against the wind.

WINDAGE *of a gun, mortar, or howitzer.* The difference between the diameter of the bore, and the diameter of the shot or shell.

WINE. All wines contain an acid, alcohol, tartar, extract, aroma, and colouring matter. The presence and nature of each of these principles may be ascertained in the following way:—

1. Acid. All wines, even the softest and mildest, redden litmus, and therefore contain an acid. This abounds, however, chiefly in the thin wines of wet and cold climates, where the grape juice or must contains but a small portion of sugar. When wine has been boiled to extract the brandy, the liquor that remains in the still, and is thrown away as useless, is a sour nauseous fluid with an acrid and burnt flavour. When filtered and allowed to remain at rest for a time, it deposits a good deal of extractive matter, becomes covered with mould, and then contains a notable quantity of acetous acid, which may be separated by distillation. The wines that contain the greatest quantity of these acids yield the worst brandy, nor is there any method yet known of separating or neutralizing the acid without materially injuring the quality, or lessening the quantity of the ardent spirit. 2. Alcohol. The existence of this principle and mode of extraction by distillation has been fully described under the article brandy. The quantity of alcohol varies prodigiously. The strong, rich, full-bodied wines of the warmer vine countries will yield as much as a third of ardent spirit; whilst the thin light wines will often give no more than about one-sixteenth of the same strength. 3. Tartar. This substance has also been fully described in its proper place. Tartar is not altogether a product of the fermentation of wine, since it is contained in must, though in small quantity. 4. Extract. Must contains an abundance of extractive matter, which materially assists the fermentation, and is afterwards found, in part at least, in the lees, but another portion may be obtained from the wine by evaporation. It is also extract that mixes with and colours the tartar. By age the quantity of extractive matter diminishes. 5. Aroma. All wines possess a peculiar and grateful smell, which would indicate a distinct aromatic principle, but it has never been exhibited in the form of essential oil, or condensed in any smaller quantity by distillation or any other mode. To give wine all its aroma it should be fermented very slowly. 6. Colouring matter. The husk of the red grape contains a good deal of colour, which is extracted when the entire fruit is pressed, and becomes dissolved in the wine when the fermentation is complete. Many substances will separate the colour. If lime-water is added to high-coloured wine, a precipitate is formed of malat of lime that carries down with it all the colouring matter, which cannot again be separated either by water or alcohol. But if wine alone is evaporated gently to dryness, and the residue treated with alcohol, the colouring matter dissolves therein. We may add, too, that the natural colour of wine is entirely and speedily destroyed by the addition of hot well-burnt charcoal in pretty fine powder. The colour of red wine in the state in which we receive it is not entirely that of the grape, but is given by other colouring substances, which, however, are quite innoxious.

WINGED, in botany, a term applied to such stems of plants as are furnished all their length with a sort of membranaceous leaves, as the thistle, &c.

WINNOWING MACHINES. Machines of this sort are in pretty general use where thrashing-mills, to which they may be attached, are not erected; they are made on different principles, according to particular circumstances.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire are gold, silver, copper, and iron.

Gold wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller; till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is no where more conspicuous than in this gilt wire. A cylinder of 48 ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr. Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain: whence 98 yards of the wire weigh no more than 49 grains, and one single grain of gold covers the 98 yards, so that the ten-thousandth part of a grain is above one-eighth of an inch long.

Wires are drawn square, and of other figures in their sector. In particular they are drawn grooved, so that any small part will form the pinion of a clock or watch work.

As the violent action of the drawing plate renders the wire hard and brittle, it is necessary to anneal it several times during the course of drawing. Very small holes are made by

hammering up the larger, and the point, in very thin wire, is made by rolling or crushing the end by a smooth burnishing tool upon a polished plate.

WIT, a faculty of the mind, consisting, according to Mr. Locke, in the assembling and putting together of those ideas, with quickness and variety, in which any resemblance or congruity can be found, in order to form pleasant pictures and agreeable visions to the fancy. This faculty, the same author observes, is just the contrary of judgment, which consists in the separating carefully from one another, such ideas wherein can be found the least difference, thereby to avoid being misled by similitude and affinity, to take one thing for another. It is the metaphor and allusion, wherein, for the most part, lies the entertainment and pleasantry of wit, which strikes so lively on the fancy, and is therefore so acceptable to all people, because its beauty appears at first sight, and there is required no labour of thought to examine what truth or reason there is in it. The mind, without looking any further, rests satisfied with the agreeableness of the picture, and the gaiety of the imagination; and it is a kind of affront to go about to examine it by the severe rules of truth or reason. Wit is also an appellation given to the person possessed of this faculty.

WITENA-MOT, or WITENA-GEMOT, among our Saxon ancestors, was a term which literally signified the assembly of the wise men, and was applied to the great council of the nation, of latter days called the parliament.

WITHERNAM, in law, a writ that lies where a distress is driven out of the county, and the sheriff cannot make deliverance to the party distrained; in that case, this writ is directed to the sheriff, commanding him to take as many of the beasts, or goods, of the party into his keeping till he make deliverance of the first distress.

WITNESS, one who is sworn to give evidence in a cause. If a man is subpœnaed as a witness upon a trial, he must appear in court on pain of £100 to be forfeited to the king, and £10 together with damages equivalent to the loss sustained by the want of his evidence to the party aggrieved.

Where a witness cannot be present at a trial, he may, by consent of the plaintiff and defendant, or by rule of court, be examined upon interrogatories at the judges' chambers. No witness is bound to appear to give evidence in a cause unless his reasonable expence is tendered him, nor need he appear till such charge is actually paid him, except he both resides and is summoned to give evidence within the bills of mortality.

WOAD, isatis, glastum, is a plant which grows wild in some parts of France, and on the coast of the Baltic Sea; the wild woad, and that which is cultivated for the use of the dyers, appear to be the same species of plant. See DYEING.

WOLFRAM. See MINERALOGY.

WOOD, *cutting in*, is used for various purposes; as for initial and figured letters, head and tail-pieces of books; and even for schemes, mathematical and other figures, to save the expense of engraving on copper: and for prints, and stamps for papers, calicoes, linens, &c. The invention of cutting in wood, as well as that in copper, is ascribed to a goldsmith of Florence but Albert Durer and Lucas brought both these arts to perfection. About two hundred years ago, the art of cutting in wood was carried to a very great pitch, and might even vie, for beauty and neatness, with that of engraving on copper. See ENGRAVING.

WOODY-FIBRE, or LIGNIN. If a piece of wood be boiled in a great quantity of water, till it no longer gives out taste or smell, and if it be afterwards digested in alcohol, the substance which remains is the woody fibre. It is either in a fibrous, lamellated, or pulverulent form. This substance, which is more or less coloured, has neither taste nor smell; is not altered by exposure to the air; and is insoluble in water and alcohol. When it is heated in contact with air, it blackens, exhales dense, acrid, pungent fumes, and leaves behind a coaly matter, which does not change its form. By reducing it to ashes, it is found to contain a little potash, sulphate of potash and lime, and phosphate of lime. When it is distilled in a retort it yields water, acetic acid contaminated with oil, a thick oily matter, carbonated hydrogen, and carbonic acid gases, and a portion of ammonia, combined with acetic acid. The pure ligneous fibre is decomposed by being heated with strong nitric acid, and yields a very considerable quantity of oxalic and malic acid.

WOOL, the covering of sheep. Each fleece consists of wool of several qualities and degrees of fineness, which the dealers therein take care to separate by a process called wool-sorting.

The fineness and plenty of our wool is owing in a great measure, to the short sweet grass in many of our pastures and downs; though the advantage of our sheep feeding on this grass all the year, without being obliged to be shut up under cover during the winter, or to secure them from wolves at other times, contributes not a little to it.

WOOL-COMBERS. By 35 G. III., c. 124, all those who have served an apprenticeship to the trade of a wool-comber, or who are by law entitled to exercise the same, and also their wives and children, may set up and exercise such trade, or any other trade or business they are apt and able for, in any town or place within this kingdom, without any molestation; nor shall they be removeable from such place by the poor laws.

WORD, in a military sense, signifies signal, token, order, as watch-word.

The WORD, *Watch* WORD, is a peculiar word that serves for a token and mark of distinction, given out in the orders of the day in time of peace, but in war every evening in the field, by the general who commands, and in garrison by the governor, or other officer commanding in chief, to prevent surprise, and hinder an enemy, or any treacherous person, from passing backwards and forwards.

WORD, in language, an articulate sound, representing some idea or conception, of the mind. The copiousness of the English language is proved by the following enumeration of the words in Johnson's Dictionary;

Articles	3
Nouns substantive	20409
Adjectives	9053
Pronouns	41

Verbs	active	5445	7880
	neuter	2425	
	passive	1	
	defective (or imperfect)	5	
	auxiliary	1	
	impersonal	3	
Verbal noun			1
Participles			38
Participial	adjectives		125
	nouns		3
Adverbs		496	2592
——— in *ly*		2096	
Prepositions			69
Conjunctions			19
Interjections			63
Total			40301

It must be remarked, however, that in this list many of the compound words are not reckoned; that the participles are those only having no verbs to which they may be referred, as *beloved*; that though so few verbal and participial nouns are stated by Johnson, yet every active verb may supply one of the former description, and every verb one of the latter; and that both these (verbal and participial nouns) seem to be merely different applications of a true gerund.

WORKING *in harvest.* A person may go abroad to work in harvest, carrying with him a certificate from the minister, and one churchwarden or overseer, that he has a dwelling-house or place, in which he inhabits, and has left wife and children, or some of them, there (or elsewhere as his condition shall require,) and declaring him an inhabitant there. A person carrying such certificate with him shall not be apprehended under the stat. 17 G. II. c. 5, commonly called the vagrant act.

WORMS. See VERMES, and MEDICINE.

WORMWOOD. See ARTEMISIA.

WORSTED, a kind of woollen thread, which, in the spinning, is twisted harder than ordinary. It is chiefly used either wove or knit into stockings, caps, gloves, or the like.

WREATH, in heraldry, a roll of fine linen or silk consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest.

WRECK, such goods as, after a shipwreck, are cast upon the land by the sea, and left there within some county, for they are not wrecks so long as they remain at sea, being within the jurisdiction of the Admiralty.

WREN. See MOTACILLA.

WRIST. See ANATOMY.

WRIT, is the king's precept, by which any thing is commanded touching a suit or action; as the defendant or tenant to be summoned, a distress to be taken, a disseisin to be redressed, &c. And these writs are diversely divided; some in respect of their order, or manner of granting, are termed original, and some judicial.

WRIT *of inquiry of damages,* a judicial writ that issues out to the sheriff, upon a judgment by default, in action of the case, covenant, trespass, trover, &c. commanding him to summon a jury to enquire what damages the plaintiff has sustained occasione præmissiorum; and when this is returned with the inquisition, the rule for judgment is given upon it: and if nothing is said to the contrary, judgment is thereupon entered.

WRITERS *to the Signet,* a term used in Scotland to designate solicitors, who conduct causes before the courts of Edinburgh; they are so named from their having had the exclusive right of preparing papers which required the king's signet.

WRONG *stamp.* By 37 George III. c. 136, any instrument (except bills of exchange, promissory notes, or other notes, drafts, or orders) liable to stamp-duty, whereon shall be impressed any stamp of a different denomination, but of an equal or greater value than the stamp required, may be stamped with the proper stamp after the execution, on payment of duty and five pounds penalty, but without any allowance for the wrong stamp.

Likewise any such instrument (except as aforesaid) being engrossed without having been first stamped, or having a stamp thereon of less value than required, the same may be stamped after the execution, on payment of the duty and ten pounds penalty only, for each skin thereof: but in case it shall be satisfactorily proved to the commissioners of stamps, that the same hath been so engrossed either by accident or inadvertency, or from urgent necessity, or unavoidable circumstances, and without any intention of fraud, the Commissioners are authorized to stamp the same within sixty days after the execution, to remit the penalty in part, or in all, and to indemnify persons so engrossing the same.

WURMBEA, a genus of plants of the class and order hexandria trigynia. There are three species, herbs of the Cape.

X.

X, or x, the twenty-second letter of our alphabet. In numerals it expresses 10, whence in old Roman manuscripts it is used for denarius; and as such seems to be made of two V's placed one over the other. When a dash is added over it, thus $\bar{X}$, it signifies ten thousand.

XANTHE, a genus of plants of the class and order dioecia syngenesia. There are two species, shrubs of Guiana.

XANTHIUM, a genus of plants of the class monoecia, order pentandria, and arranged in the natural classification under the 49th order compositæ. There are five species, only one of which is a native of Britain, the strumarium or lesser burdock. Horses and goats eat it; cows, sheep, and swine, refuse it.

XANTHIORZA, a genus of plants of the class and order pentandria polygamia. There [illegible]ies, a shrub of North America.

XANTHOXYLUM, the tooth ache tree, a genus of plants of the class and order diœcia pentandria. There is one species, a tree of Jamaica.

XIMENIA, a genus of plants of the class and order pentandria monogynia. The calyx is a perianthium, composed of three small, cordated and deciduous leaves. There are three species, trees of the West Indies.

XIPHIAS, the *sword-fish*, in natural history, a genus of fishes of the order, apodes; generic character: head with the upper jaw ending in a sword shaped snout: mouth without teeth: gill-membrane eight-rayed; body roundish, without scales. There are three species; Xiphias, gladeus, or the common sword-fish, is of the length of twenty-feet, and is particularly distinguished by its upper jaw being stretched to a considerable distance beyond the lower, flat above and beneath, but edges at the sides, and of a bony substance, covered by a strong epidermis. It is a fish extremely rapacious, and finds in the above instrument a weapon of attack and destruction, able to procure it the most ample supplies. It first transfixes its prey with this snout, and then devours it. It is found in the Mediterranean, chiefly about Sicily, and is used as food by the Sicilians, who preserve it for a long time [illegible], salting it in small pieces.

Xiphias, *platypterus*, or the broad-finned sword-fish, is found in the Northern, Atlantic, and Indian Seas, and is considered as one of the most fatal enemies of the whale tribe. Its strength is so great that it is said to have pervaded with its snout, or sword, the plank of an East Indiaman; and a plank and snout in attestation of this circumstance, the latter closely driven [illegible] the former, are to be seen in the British Museum, having been communicated to Sir Joseph Banks by an East India Captain, of honour and veracity. When young this fish is used for food, but after it exceeds four or five feet in length.

XIPHIDIUM, a genus of plants of the class and order triandria monogynia. There is one species, a herb of the West Indies.

XYLO-ALOES, or ALOE-WOOD, in pharmacy. See EXCOECARIA.

XYLOCARPUS, a genus of plants of the class and order octandria monogynia. There is one species, a tree of the East Indies.

XYLOPHYLLA, a genus of plants of the class and order pentandria trigynia. There are seven species, shrubs of the West Indies.

XYLOPIA, a genus of plants of the class and order polyandria polygynia. There are three species, trees of the West Indies.

XYLOSMA, a genus of plants of the class and order dioecia polyandria. There are two species

XYRIS, a genus of the triandria monogynia class of plants, the flower of which consists of three plain, patent, large, crenated petals, with narrow ungues, of the length of the cup There are three species.

Y.

Y, the twenty-third letter of our alphabet. [illegible] is a numeral, signifying 150, or according to Baronius, 159; and with a dash at top, as $\overline{Y}$, it signifies 150,000.

YACHT. This word is taken from the Dutch. It is a small ship with one deck, carrying four, eight, or twelve guns, and thirty or forty men. Yachts, in general, are from thirty to 160 tons; contrived and adorned both withinside and without, for carrying state passengers. They answer the purposes of business as well as pleasure, being remarkably good sailers.

YANOLITE, AXINITE, or THUMERSONE, which see.

YARD. See MEASURE.

YARDS *of a ship*, are those long pieces of timber which are made a little tapering at each end, and are fitted each athwart its proper mast, with the sails made fast to them, so as to be hoisted up, or lowered down, as occasion serves. They have their names from the masts to which they belong.

Yards also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. There are, belonging to his Majesty's navy, six great yards, viz. Chatham, Deptford, Woolwich, Portsmouth, Sheerness, and Plymouth; these yards are fitted with several docks, wharfs, launches, and graving places, for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores, needful for the royal navy.

YARD ARM is that half of the yard that is on either side of the mast, when it lies athwart the ship.

YEAR, the time that the sun takes to go through the twelve signs of the zodiac. See CHRONOLOGY.

Year, or *solar year*, properly, and by way of eminence so called, is the space of time in which the sun moves through the twelve signs of the ecliptic. This, by the observations of the best modern astronomers, contains 365 days, 5 hours, 48 minutes, 48 seconds; the quantity assumed by the authors of the Gregorian calendar is 365 days, 5 hours, 49 minutes. But in the civil or popular account, this year contains only 365 days, except every fourth year, which contains 366.

Common civil year, is that consisting of 365 days; having seven months of thirty-one days each, four of thirty days, and one of twenty-eight days; as indicated by the following well-known memorial lines:

> Thirty days have September,
> April, June, and November;
> February twenty-eight alone,
> And all the rest have thirty-one.

Bissextile or leap-year, consists of 366 days, having one day extraordinary, called the intercalary, or bissextile day, which takes place every fourth year.

YEAR *and* **DAY**, is a time that determines a right in many cases; and in some works an usurpation, and in others a prescription; as in case of an estray, if the owner

proclamation being made, challenges it not within the time, it is forfeited. So is the year and day given in case of appeal; in case of descent after entry or claim, if no claim [illegible] on a fine or writ of right at the common law; so of a villein remaining in ancient demesne; of a man sore bruised or wounded; of protections; essoins in respect of the king's service; of a wreck; and divers other cases.

YEAR DAY *and* **WASTE**, is a part of the king's prerogative, whereby he challenges the profits of their lands and tenements for a year and a day, that are attainted of petty treason or felony, whoever is lord of the manor where the lands or tenements belong; and not only so, but in the end may waste the tenements, destroy the houses, root up the woods, garden, and pasture, and plough up the meadows, except the lord of the fee agrees with him for redemption of such waste afterwards restoring it to the lord of the fee.

YEARS *estate for*. Tenant for term of years, is where a man lets land or tenements to another, for a certain term of years agreed upon between the lessor and lessee; and when the lessee enters by force of the lease, then he is tenant for term of years.

YEAST, or *barm*, is the head, or scum which rises upon beer or ale during the process of fermentation. It is used for a leaven or ferment in the baking of bread, as serving to swell or puff it up very considerably in a little time, and to make it much lighter, softer, and more delicate. When there is too much of it, it renders the bread bitter. The following beautiful description of this process is given by Dr. Ure, in his Dictionary.

It is to the gluten that wheat flour owes its property of making a fermentable dough with water. This flour paste may indeed be regarded as merely a viscid and elastic tissue of gluten, the interstices of which are filled with starch, albumen, and sugar. We know that it is from the gluten that the dough derives its property of rising on the admixture of leaven. The leaven acting on the sweet principle of the wheat, gives rise in succession to the vinous and acetous fermentations, and of consequence to alcohol, acetic and carbonic acids. The latter gas tends to fly off, but the gluten resists its disengagement, expands like a membrane, forms a multitude of little cavities, which give lightness and sponginess to the bread. For the want of gluten, the flour of all those grains and roots which consist chiefly of starch are not capable of making raised bread, even with the addition of leaven or yeast. There does not appear to be any peculiar fermentation to which the name *panary* should be given.

This invaluable article in domestic economy is, at certain seasons of the year, very scarce in this country, and at those times what is to be obtained is generally of an inferior quality. Various expedients have been tried to remedy this defect, but the best ever made known to the public is unquestionably that described by Mr. W. Cobbet, as practised by the people of Long Island, America, which is as follows:

Rub between the hands three ounces of hops, so as to separate them, and then put them into a gallon of boiling water, where they are to boil for half an hour. Now strain the liquor through a fine sieve into an earthen vessel, and while it is hot, put in three pounds and a half of rye flour; stirring the liquor well, and quickly as the flour is put in. When it has become as cool as wort for brewing, add half a pint of good yeast. On the following day, whilst the mixture is fermenting or working, stir well into it seven pounds of Indian-corn meal; this will render the whole mass stiff like dough; this dough is to be well kneaded and rolled out into cakes about a third of an inch in thickness. These cakes are to be cut out into large disks, or lozenges, or any other shape, by an inverted tumbler or other instrument; and being placed on a sheet of tinned iron, or on a piece of board, are to be dried by the heat of the sun. If care be taken that they are frequently turned, and that they receive no wet or moisture, they will become as hard as ship-biscuit, and may be kept in a bag or box, which is to be hung up, or kept in an airy and perfectly dry situation. When bread is to be made, two cakes of the above mentioned thickness, and about three inches in diameter, are to be broken and put into hot water, where they are to remain all night; the vessel standing near the fire. In the morning they will be entirely dissolved, and then, the mixture is to be employed in setting the sponge in the same way that beer yeast is used.

YELLOW *earth*, named by Werner, gelberde, is of a yellow ochre colour of various degrees of intensity. It is massive, soft and friable: it adheres strongly to the tongue and feels greasy. It occurs in beds with iron-stone in Upper Saxony, and is employed as a yellow pigment.

YELLOW, *Naples*, a fine pigment so called from the city in which it was long prepared. It has the appearance of an earth, is very friable, heavy, porous, and not altered by exposure to the air.

YEOMAN, is defined to be one that hath fee land of 40*s*. a year; who was thereby, heretofore, qualified to serve on juries, and can yet vote for knights of the shire, and do any other act where the law requires one that is *probus et legalis homo*.

YEOMAN *of the guard*, one belonging to a sort of foot guards, who attend at the palace. The yeomen were uniformly required to be six feet high. They are in number 100 on constant duty, and 70 off duty. The one half carry arquebuses, and the other pertuisans. Their attendance is confined to the sovereign's person, both at home and abroad. They are clad after the manner of king Henry VIII.

YEW. See TAXUS.

YOKE, in agriculture, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

YOLK, a word used to designate the yellow part of an egg, from which the chick is produced. In the yolk of eggs there is a considerable quantity of oily matter, which may be obtained by pressure after boiling. This oil is yellow and tasteless.

The term yolk is also used for an animal soap which is found in wool, and which seems designed by nature as a preservative of that article.

YTTRIA. This is a new earth discovered in 1794 by Prof. Gadolin, in a stone from Ytterby in Sweden. See GADOLINITE.

It may be obtained most readily by fusing

the gadolinite with two parts of caustic potash, washing the mass with boiling water, and filtering the liquor, which is of a fine green.

Yttria is perfectly white, when not contaminated with oxide of manganese, from which it is not easily freed. Its specific gravity is 4.842. It has neither taste nor smell. It is infusible alone; but with borax melts into a transparent glass, or opaque white if the borax were in excess. It is insoluble in water, and in caustic fixed alkalis; but it dissolves in carbonate of ammonia, though it requires five or six times as much as glucine. It is soluble in most of the acids.

When yttria is treated with potassium in the same manner as the other earths, similar results are obtained; the potassium becomes potash, and the earth gains appearances of metallization; so that it is scarcely to be doubted, says Sir H. Davy, that yttria consists of inflammable matter, metallic in its nature, combined with oxygen.

YUCCA, *Adam's needle*, a genus of plants of the class *hexandria*, and order *monogynia*. There are four species, but none of them natives of Britain.

YUNX, in zoology, a genus of birds of the order picæ. The bill is short, roundish, and pointed; the nostrils concave and naked; the tongue very long and cylindric; there are two fore and two hind claws. There is only one species, the torquilla, wry-neck, which is a native of Europe, Asia, and Africa, and is often seen in Britain.

Z

Z, the twenty-fourth and last letter of our alphabet.

In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it has in earlier times been used to express the third part of an ounce, or eight scruples.

Z Z were used by the ancient physicians to express myrrh, and they are sometimes used at present to signify zinziber, or ginger.

ZAFFRE, is the oxide of cobalt, employed for painting pottery-ware and cobalt of a blue colour. See COBALT.

ZAMIA, a genus of the natural order of palmæ. The ament is shobile-shaped, scales with pollen underneath; fem. ament. shobile-shaped with scales at each margin; berry solitary. There are five species.

ZANNICHELLIA, horned pond-weed, a genus of the monœcia monandria class of plants, the male flower of which consists only of a single stamen; it has neither calyx nor corolla. In the female flower the calyx is composed of a single leaf; there is no corolla. There is one species.

ZEA, *Indian corn*, a genus of plants of the class monœcia, order triandria. There is only one species, the mays, or maize. The Indians in New England, and many other parts of America, have no other vegetable but maize or Indian corn for making their bread. They call it weachin, and in the United States of America there is much of the bread of the country made of this grain, not of the European corn. In Italy, Germany, Spain, and Portugal, maize constitutes a great part of the food of the poor inhabitants.

ZEBRA. See EQUUS.

ZENITH, in astronomy, the vertical point; or a point in the heavens directly over our heads.

ZEOLITE. See MINERALOGY.

ZERO, signifies the commencement of the graduation of the scale of the thermometer, and is marked 0. In Farenheit's thermometer this is 32° below the freezing point; and in Reamur it coincides with the freezing point, as it does also in the centigrade thermometer

ZEUS, in ichthyology, a genus of fishes of the order of thoracici. The head is compressed and declines, the upper lip being vaulted over by a transverse membrane; the tongue is subulated; there are seven rays in the gill-membrane; and the body is compressed. The species are eight; of which the most remarkable is the faber or doree.

ZIMOME. The gluten of wheat, treated by alcohol, is reduced to the third part of its bulk. This diminution is owing, not merely to the loss of gliadine, but likewise to that of water The residue is zimome, which may be obtained pure by boiling it repeatedly in alcohol, or by digesting it in repeated portions of that liquid cold, till it no longer gives out any gliadine.

ZINC is a metal of a bluish-white colour, somewhat brighter than lead; of considerable hardness, and so malleable as not to be broken with the hammer, though it cannot be much extended in this way. It is very easily extended by the rollers of the flatting mill. Its specific gravity is from 6.9 to 7.2. See CHEMISTRY.

ZIRCON. See MINERALOGY.

ZIZANIA, a genus of plants of the class monœcia, order hexandria; and in the natural system arranged under the 4th order, gramina. There are two species; the aquatica and terrestris, none of which are natives of Britain.

ZODIAC. See ASTRONOMY.

ZODIACAL *light*, a brightness sometimes observed in the zodiac, resembling that of the galaxy, or milky way. It appears at certain seasons, viz. towards the end of winter, and in spring after sun-set, or before his rising in autumn and beginning of winter, resembling the form of a pyramid, lying lengthways with its axis along the zodiac, its base being placed obliquely with respect to the horizon.

ZONE, in geography and astronomy, a division of the terraqueous globe, with respect to the different degree of heat found in [illegible] parts. A zone is the fifth part of the surface of the earth, contained between two parallels. The zones are denominated torrid, frigid, and temperate. The torrid zone is a band surrounding the terraqueous globe, and terminate

by the two tropics Its breadth is 46 deg 58 min The equator, running through the middle of it, divides it into two equal parts, each containing 23 deg 29 min. The ancients imagined the torrid zone uninhabitable The temperate zones are two bands, environing the globe, and contained between the tropics and the polar circles, the breadth of each is 43 deg 2 min. The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the artic circle The breadth of each is 46 deg 38 min

ZOOLOGY, is that part of natural history which relates to animals

In order to abridge the study of zoology, many methods of reducing animals to classes, genera, and species, have been invented but as that of Linnæus is undoubtedly the best, the most extensive, and the most generally adopted, we shall give a brief account of it

Linnæus divides the whole animal kingdom into six classes The characters of these six classes are taken from the internal structure of animals, in the following manner —

Class I *Mammalia* includes all animals that suckle their young The characters of this class are these The heart has two ventricles and two auricles, the blood is red and warm, and the animals belonging to it are viviparous.

Class II *Aves*, or birds The characters are the same with those of Class I excepting that the animals belonging to it are oviparous

Class III *Amphibia*, or amphibious animals The heart has but one ventricle and one auricle, the blood is red and cold, and the animals belonging to this class have the command of their lungs, so that the intervals between inspiration and expiration are in some measure voluntary

Class IV *Pisces*, or fishes The heart has the same structure, and the blood the same qualities with those of the amphibia but the animals belonging to this class are easily distinguished from the amphibia by having no such voluntary command of their lungs, and by having external branchiæ or gills

Class V *Insecta* or insects The heart has one ventricle, but no auricle the blood is cold and white, and the animals are furnished with antennæ or feelers See Insect

Class VI *Vermes* or worms The characters are the same with those of Class V only the animals have no antennæ, and are furnished with tentacula

For subdivision of these classes into orders see under the various articles, *Mammalia*, *Aves*, *Amphibia*, *Pisces*, *Insecta*, and *Vermes*

ZOOPHYTA, in natural history, an order of the class vermes Zoophyta are composite animals, holding a medium between animals and vegetables Most of them take root and grow up into stems, multiplying life in their branches and deciduous buds and in the transformation of their animated blossoms or polypes, which are endowed with spontaneous motion. Plants, therefore, resemble zoophyta, but are destitute of animation and the power of locomotion, and zoophyta are, as it were, plants, but furnished with sensation and the organs of spontaneous motion Of these some are [illegible] and naked, and others are covered with a hard shell the former are by some naturalists called zoophytes, and the latter are denominated lithophytes

The coral reefs that surround many islands particularly those in the Indian Archipelago, and round New Holland are formed by various tribes of these animals, particularly by the Cellepora, Isis, Madrepora, Millepora, and Tubipora The anim[illegible] in these corals with such rapidity that enormous masses of them very speedily appear where there were scarcely any marks of such reefs before

ZOSTERA, a genus of plants of the class gynandria, order polyandria, and in the natural system arranged under the second order piperitæ There is one species

ZWINGERA, a genus of the class and order of plants decandria monogynia There is one species, the amara, resembling quassia, a shrub of Guiana

ZYGÆNA See Squalus

ZYGIA a genus of insects of the order coleoptera The generic character is antennæ moniliform, feelers equal, filiform lip elongated, membranaceous jaw one toothed

ZYGOPHYLLUM *bean caper*, a genus of plants of the class of decandria and order monogynia and in the natural system arranged under the 14th order gruinales There are 11 species, partly shrubby and partly herbaceous plants, all natives of warm climates though some of them are hardy enough to endure the open air in this country

ZYMOSIMETER an instrument proposed by Swammerdam for the purpose of measuring the degree of fermentation occasioned by the mixture of different substances and the degree of heat attending such fermentation

---

Printed by J Maddison, Castle street Finsbury
